IT is often necessary in clinical work to determine the state of permeability of the arteries of the upper or lower limbs. In obliterating arteritis the need for determining the presence of an obliteration, its degree, its localization, and also the condition of the collateral circulation, is frequently felt. In arterial or arterio-venous aneurysms it is necessary to know if the limb is receiving a normal blood supply. In diabetes, in arterio-sclerosis, and in other morbid conditions the degree of permeability of the arteries of the limbs—especially of the lower limbs—is important from the points of view of diagnosis and prognosis. There are not many clinical methods which assist in answering these clinical problems. Digital examination of the radial or the femoral artery or the dorsalis pedis does not give very definite results. The Moschcowitz and Matas tests, which utilize the degree of the hyperaemic blush following artificial ischaemia caused by the application of an elastic bandage, also fail to give very definite results, and are not without danger in their application.

In 1912 I introduced the oscillometric method for the study of arterial permeability.[1] It is based on the use of Pachon's oscillometer, and has been developed in France by a great number of workers—principally by Heitz,[2]

* Tartar emetic was shown recently by Fairley[7] to be relatively innocuous to bilharzia cercaria in aqueous solutions, but it developed marked lethal properties in the presence of human serums derived from both normal and bilharzia patients

Guyot and Jeanneney,[3] Pagniez,[4] Gosset, Rénon, and others. An excellent review of this method has been given by Gallavardin[5] in his standard work on the arterial pressure, and by Pachon[6] in a paper on the oscillometry. If the work of Matas[7] be excepted, this method of examination is not used extensively in English-speaking countries. Buerger, in his review of the circulatory disturbances of the extremities, does not appear to have followed the literature on this subject, although for the diagnosis of the syndrome of arterial obturation and of thrombo-angiitis obliterans the oscillometric method is, in my opinion, very valuable.

The Method.

Pachon's oscillometer shows the oscillations of the arterial wall under progressive pressure with great accuracy. Fig. 1 shows the oscillations obtained after the armlet has been inflated until no oscillations are shown on the dial of the oscillometer. If the air is allowed to escape very gradually by the valve of the apparatus, and the index of the dial which indicates the oscillations is watched, at first a series of small and equal oscillations, which are called the supramaximal oscillations, are detected. Then comes an oscillation distinctly differing in its extent—the "differentiated oscillation." The oscillations continue to increase progressively and then diminish, and there may therefore be detected the maximum oscillation (MA) and immediately after this maximum oscillation the first descending oscillation (DF). By allowing the air to escape gradually small oscillations are reached once more, and the terminal oscillation (TE) may be determined.

Pachon, his pupils, and various other clinicians use the oscillometric method for the determination of blood pressure. The differentiated oscillation corresponds for Pachon to the systolic pressure, and the degree of this pressure is shown by reading the manometer of the apparatus. The first descending oscillation (DF) indicates the diastolic pressure.

For the application of the oscillometric method to the study of arterial permeability the two oscillations—DI and DF—necessary for the determination of the blood pressure need not be considered, but the three other oscillations—the initial oscillation, IN, the maximum oscillation, MA, and the terminal oscillation, TE—must be determined. More precisely we must try to determine: (1) the degree of pressure under which the initial (IN) and terminal oscillations appear; (2) the extent—in divisions of the dial of the oscillometer—of the maximum oscillation. This last determination, Pachon's oscillometric index, is the most important. This point should be thoroughly understood, and there must be no confusion between the application of the oscillometer for the determination of the blood pressure in general and its application for the determination of arterial permeability.

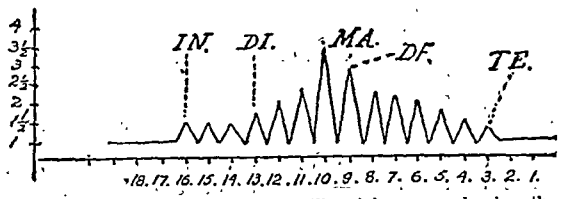

FIG. 1.—Diagrammatic clinical oscillometric curve, showing the oscillations as obtained in progressive decompression of the armlet of the oscillometer. The horizontal line indicates the pressure as read in the manometer. (For the corresponding English divisions a zero — must be added. Example: 18 is 180 mm. of mercury, 13 is 130 mm. of mercury.) The vertical line indicates the divisions of the dial measuring the extent of the oscillations. IN=Initial oscillation. DI=Differentiated oscillation. MA=Maximum oscillation. DF=First descending oscillation. TE=Terminal oscillation.

If the whole oscillometric curve be determined, or, more simply, if the numbers of the manometer corresponding to the three oscillations under consideration—the initial, the maximum, and the terminal—be noted, it will be found that under normal conditions in the upper limbs the initial is at about 15 or 16 (150 to 160 mm., using the mode of notation customary in England), the maximum extends to 2 or 3 degrees of the dial, and the terminal is found at about 6 or 7. The simple mode of notation 15—3°—7 is here adopted. In the lower limbs the initial is found at about 18, the maximum oscillation extends to 3 or 4 degrees, and the terminal oscillation is also found at about 7 or 6. Adopting the simple notation this may be stated for the lower limbs as 18—4°—6.

This is, of course, schematic because there are many individual variations, and in order to appreciate the differences in the oscillometric curves indicating arterial permeability, it is best to compare the oscillometric curves obtained in different arterial segments by applying the armlet of the oscillometer in various positions on the upper and lower limbs. A special "armlet" has been constructed by Boulitto for the thigh.

In cases of diminished arterial permeability of an artery of the limbs what may be called the oscillometric curve

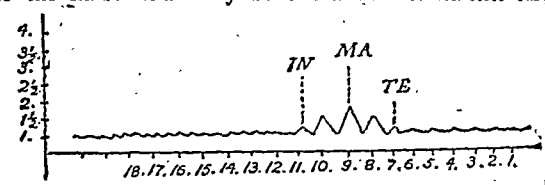

FIG. 2.—Oscillometric curve of arterial obstruction IN=Initial oscillation. MA=Maximum oscillation. TE=Terminal oscillation.

of arterial obstruction is found (Fig. 2), in which the initial oscillation appears at a lower pressure (say 7), the amplitude of the maximum oscillation is diminished (for example, to half a degree of the dial), and the terminal oscillation appears at a higher pressure than normally (say 6). This curve indicates that the oscillations of the arterial wall appear later, finish earlier, and are of less amplitude than normally. In other words, as Gallavardin puts it, the "pulsatility" of the artery is diminished.

Clinical Application.

1. The oscillometric examination of arterial permeability helps in determining whether obliteration exists, and thus in diagnosing whether a syndrome of intermittent claudication is due to an arterial obliteration or to a nervous cause (medullary intermittent claudication, a syndrome of the initial period of Erb's spastic paraplegia).

K. shows a definite symptom-complex of intermittent claudication. Oscillometric examination of the arterial permeability in the two lower limbs 12—1—6; in the two upper limbs 15—4—10. This patient had syphilis and certain difficulty on walking. The onset of a nervous spasmodic syphilitic paraplegia was suspected, but the oscillometric method allowed the diagnosis of the arterial origin of the disturbance to be made, and this diagnosis was confirmed at *post-mortem* examination, which showed the presence of big plaques of atheroma of the two external iliac arteries, almost completely obturating these vessels.

S., a diabetic, complains of numbness in the lower limbs and certain difficulty in walking. The oscillometric exploration shows low numbers for the left lower limb and less low for the right lower limb. This enabled the diagnosis of arterial origin of these disturbances to be made, a diagnosis which was confirmed by the appearance during the next year of early gangrene of the left toe.

When the collateral circulation is good, even although a main artery is obliterated, the oscillometric results are not abnormal findings. A negative result must not be considered, therefore, as absolute.

2. The oscillometric method allows the course of the disease and the effect of treatment to be followed.

K., aged 30, seen in Paris in 1910. Oscillometric mensurations: lower right limb 14—2—6, lower left limb 7—1/2—4; upper limbs 14—3—9. After a series of treatment in Royat he was examined two years later. He felt considerably better. Oscillometric mensurations of lower limbs: right 15—2—9, left 9—1/2—5. This satisfactory condition did not persist long, and after two years the readings for the upper limbs were 14—3—9; lower right 14—2—9, lower left 6—1/2—5. One year after no oscillation was detected in the left lower limb.

3. The oscillometric method enables a diagnosis to be made between arterial obliteration due to spasm and that due to definite organic obstacles. As Heitz has shown, when it is caused by spasm a hot local bath brings back normal oscillometric readings.

4. Oscillometric exploration allows the localization of the obliteration to be determined; the obturations curve being found precisely at the region of the obturation and under that region.

5. Oscillometric estimations have been applied to the examination of the arterial circulation in cases of arterial

and arterio-venous aneurysm by the author; as well as by Gosset, by Matas, and by Rénon.

M., Colonel in the Greek army, wounded at Kilkis, and showing an arterio-venous aneurysm in the right axilla. Oscillometric examination of the forearm: left 14–2–10, right 10–1–7. Two weeks after operation by Professor Gosset the initial oscillation was–12. Ten months after it was 13–2–8. The radial pulse could not be felt; oscillations were therefore due to collateral circulation.

This method also shows if a collateral circulation persists in a limb after extirpation of an arterial aneurysm. This is done by taking the oscillometric readings before and after compression of the artery under the aneurysm. If the oscillometric readings are good after compression, extirpation can be applied without danger.

6. Lastly, oscillometric examination will demonstrate the obliteration of a radial artery by an aortic aneurysm or by a tumour of the mediastinum. The involved artery will show the oscillometric curve of arterial obstruction.

Summary.

Pachon's oscillometer is a very simple clinical instrument and easy to apply. With a little practice anyone can determine the state of the permeability of the tibial artery, of the femoral artery, of the artery of the forearm, and of the brachial artery, and thus study an important element of the peripheral arterial circulation of the patient.

THE TREATMENT OF BURNS.

BY

D. MACKENZIE, M.B., CH.B.GLASG.,

SOUTHERN GENERAL HOSPITAL, GOVAN.

THIS note is the outcome of fourteen months' experience as house-surgeon in burns wards. There every known method of dealing with the primary shock and in the aseptic and antiseptic treatment of the burns was tried.

During the last five years I have used as a routine Wright's hypertonic saline (NaCl), with its recognized valuable results[1]; this in association with more active measures is the keynote of the method.

The line of treatment advocated is active surgical intervention, and consists of the immediate removal of all dead tissues under a general anaesthetic—preferably ether. The appreciation of what may be termed the demarcation line is soon acquired. My approach towards this appreciation was the removal of the dead tissue in fourth and fifth degree burns on the seventh day, at which time natural separation is appreciable, and thereafter proceeding in subsequent cases to earlier and eventually earliest removal. The degree of appreciation is not important, provided the error, if any, is on the side of free removal. The aim is the formation of a surgical field, and free removal, both at the skin and deep margin, is indicated. The presence of dead tissues results in toxaemia from the absorption of the products of autolysis, and usually a degree of septicaemia at the sloughing stage. To avoid this is the chief purpose; complete removal leaves a surgical field with the subsequent healthy granulation tissue of aseptic surgery.

The instruments used in the removal of dead tissue are razors, amputation knives, Volkmann spoons, heavy curettes, different types of scissors, toothed dissecting forceps, haemostatic forceps, etc. Where bone is involved the appropriate instruments are added. The solution employed is hypertonic (NaCl). When demarcation has been exact there has been no danger of haemorrhage from oozing with applications of 5 per cent. hypertonic saline, or, where oozing is extensive, 2 to 3 per cent. In no case has there been haemorrhage. The gauze is wrung out of the hot saline and applied in close contact to the raw surface, layer on layer, and covered with wool. Jaconet is used as a covering where modification of the hypertonicity and the nature of the field might result in a painful adherent dressing. The gauze is removed by warm saline, irrigation, as distinct from soaking, being employed. At a later stage in the repair, the stage where physiological saline is replacing hypertonic, "V" flap perforated silk is interposed to guard the granulations if required. The question of dressing daily, or twice daily, is particular to the case. Within a few days parts of the field are in most cases ready for pinch-grafts, provision for which should be made at the operation. When dealing with the skin margin, shelving of the margin is adopted, but at different parts small portions of the skin are left jutting towards the raw area, and these portions, when required, are readily removed by scissors curved on the flat. General pinch-grafting is governed by absolute freedom from dead tissue or sepsis and by the degree of granulation desired to replace loss of tissue. Dead tissue which may have been missed at operation should be dealt with by sharp scalpel or razor; for smaller portions the virtue of hypertonic saline need not be enlarged upon. A bland ointment is used to protect the rapidly germinating epithelium, otherwise physiological or hypertonic solutions of NaCl are employed throughout.

The question of how early the operation should be performed has to be viewed in relation to the degree of primary shock and the degree of difficulty which may be met with in estimating the line of demarcation at the particular site of the burn. Undue delay, on the other hand, must be guarded against on the following grounds. The active measures taken in combating the shock—the electric cage, pituitrin, camphor, ether, brandy, etc.; intravenous saline, rectal injections of saline, glucose, essential oils, etc.; analgesics such as morphine, nepenthe, etc.; the various types of soothing applications, aluminium acetate, picric acid, protective wax preparations, etc.—were in part nullified by the rapid absorption of the autolytic products, this absorption from its toxaemia sustaining the shock.[1] There is also the possibility that the autolytic processes in burns modify locally the natural efforts of repair, with a resultant change in the characteristics of the fibroblastic tissue. The ground for such a belief is the modification of the scar tissue, so frequently met with in burns, ranging as it does from hypertrophic scar tissue, keloidal to keloid, which, although regarded as an individual idiosyncrasy, is nevertheless most common in burns. It must be remembered too that equally severe shock is met with in other circumstances where immediate operation is indicated. There is also the stimulating effect of ether administration, and during this intravenous saline and other shock-combating treatment may be carried out. Post-operative treatment is attended to as in other surgical cases. Lastly, there is the psychological effect on the patient when the nausea of scorched flesh is replaced by the sense of comfort from the soothing aseptic dressings, painlessly applied. The necessity to operate at a later stage, when the patient is exhausted from toxaemia, if not by septicaemia, is avoided. The convalescence, characterized by asepsis and a rapid rate of healing, is considerably shortened and is free from discomfort.

The flexible type of scar tissue resulting from this procedure, with its potentiality for plastic considerations and minimum of contractures, lessens disfigurement. The nature also of the repair process prevents the former bugbear of burns repair. This was the terminal patch usually found at the summit or centre of the field. It was due to the inequality of repair rate at the deep and superficial parts of the scar, the contraction of the deep tissue interfering with the blood supply of the patch. The result was that this area might resist all methods of healing, including grafting, and take on a malignant character. Such a malignant ulcer is not infrequently seen on an old burn scar when it has broken down from stress or trauma. Similarly the treatment lessens the possibility of hypertrophic scar tissue. The absence of keloidal or keloid tissue in the cases dealt with must at present be regarded on the score of the patients' freedom from such idiosyncrasy. The

particular value of flexible scar tissue at the flexures of the body and at tendinous areas need not be mentioned.

In large voluntarily supported institutions the economical aspect—the saving in time and material—is also a consideration.

TREATMENT OF ENCEPHALITIS LETHARGICA ASSOCIATED WITH PARKINSONISM BY ULTRA-VIOLET RAYS.

BY

RICHARD FAWCITT, M.B., CH.B.ED.,

HONORARY SURGEON, ULVERSTON COTTAGE HOSPITAL.

MY object in publishing these few cases is to interest those members of our profession who are not yet acquainted with the possibilities of treatment of this unhappy condition by means of ultra-violet rays. I cannot claim that this line of treatment works miracles, but in some cases it appears to be definitely beneficial.

Some months ago I treated a case of chronic ulcerative tonsillitis by means of ultra-violet rays (mercury vapour lamp); as the tonsils healed quickly, and a persistent rhinitis cleared up also, I was led to think that the local application of ultra-violet rays to the mucous surfaces of the nose and throat might be beneficial in encephalitis lethargica. On June 8th I began to apply it to cases to which I was already giving general ultra-violet rays with what, I think, is a certain measure of success.

My technique, except in Case 5, consisted in stripping the patients in the usual way and application of the multiple carbon arc lamp, back and front, for gradually increasing periods up to half an hour, according to the patient's capacity, twice weekly. In addition to this, local treatment was given to the mucous surfaces of the nose and tonsillar area by a mercury vapour lamp with adaptor for a period of not exceeding two minutes to each area.

The points which seem most noticeable are: improvement in gait, feeling of well-being, diminution of salivation, and relaxation of the fixed expression of the face.

Case 1.—A schoolmaster, aged 33. The onset of the disease occurred two years before he was sent to me in April, 1926. Parkinsonism was well developed; he was unable to do anything for himself. The multiple carbon arc lamp was used twice weekly. After the third application he was able to turn over on the couch; after the fifth he walked much better; after the eighth he was able to help to dress himself; his facial expression also improved very much. On May 22nd he was sent to Birmingham to Dr. Eden for lavage of his sphenoidal sinus, etc.

Case 2.—A schoolboy, aged 14, contracted the disease a year previous to coming to me on April 16th, 1926. He was in a very poor condition—was extremely breathless on going upstairs, and the journey of eight miles in the car upset him very much; his heart was considerably dilated. He had three applications, but died suddenly in his own home four days after the last application.

Case 3.—A coppersmith, aged 42, had had the disease for two years before coming for treatment on April 16th. His improvement has been very marked from the commencement, particularly as to his expression, feeling of well-being, and locomotion. On June 8th, in addition to his general treatment by means of the multiple carbon arc lamp, I gave him short local applications to the nose and throat by means of an adaptor fitted to the mercury vapour lamp; this was continued twice weekly, and has appeared to be very beneficial. He is much straighter in posture, and can use his hands much better.

Case 4.—A joiner, aged 42. Onset of disease two years previous to coming for treatment on April 16th, 1926. The Parkinsonian syndrome was present, but not so well developed in this case; salivation was very troublesome. He also had very marked stiffness of the jaw. He ceased to come on July 27th, but was considerably improved; his jaw is still very stiff, and he is having difficulty in eating.

Case 5.—A married woman, aged 38, in whom the disease first appeared two years previously. She was delivered of a healthy female child (still alive and well) a week after the onset. Came for treatment on April 16th, 1926. She was treated throughout by means of the mercury vapour lamp, local and general, and her condition is much improved.

Case 6.—A labourer, aged 32. Duration of disease fifteen months. He had very marked tremors, and used to get up from bed to come for treatment. He showed some improvement, but not much. He ceased to come June 28th, and has since been confined to bed. I am inclined to think that this is a case of disseminated sclerosis. He came on April 16th, 1926. Same treatment as above.

Case 7.—A fruiterer, aged 19. Onset of attack two years previously. His gait and posture were very bad; there was much salivation. The posture and gait have much improved, and he is much freer from salivation. He was very mischievous when he first came, but his demeanour is much improved. He came on April 16th, 1926. Same treatment as above.

Case 8.—An insurance agent, aged 49. Date of attack indefinite, but he had been going downhill for six months, and had developed Parkinsonism. Treatment was started on July 14th, 1926, and the patient shows considerable improvement.

Case 9.—An engine-driver, aged 60. Duration of disease three years. He came once, but did not like the treatment, and would not come again.

BREATHING EXERCISES WITH MOVING ARMS.

BY

HORACE HILL, M.B., B.S., M.R.C.P.,

SURGEON COMMANDER, R.N.,

R.N. SCHOOL OF PHYSICAL AND RECREATIONAL TRAINING.

SOME systems of physical training still advocate the movements of the arms during a breathing exercise.

Arm movements hamper the expansion of the thorax and the descent of the diaphragm. As soon as the arms are raised the movements of the thorax are lessened, in order that it may supply a steady base on which the arms can pivot; also to supply a fixed base for the muscles which arise from the chest and are attached to the arms to work from. In addition the shoulder girdle has to be moved. Besides the arm group other muscle groups are immediately contracted. The supporting groups of muscles, which keep the body in position while the heavy arms are moving, come into play. The muscles of the leg contract to steady the pelvis, in order that the spine and thorax may be supported on it, and not be swung off their balance by the heavy arms.

The fixation of the pelvis enables the abdominal muscles to contract and hold the thorax firm; this prevents the ribs from rising. If, in addition, the head is thrown back, as is usually recommended, the abdominal muscles can be seen and felt to be rigidly contracted. This effectually prevents the descent of the diaphragm. The spirometer and x rays confirm these statements. Keith, in a Hunterian Lecture, says that arm movements increase the pressure in the abdomen. This also impedes the diaphragm.

The mere fact that no gross movement in these abdominal muscles may be seen does not prove that no contraction is taking place. The thin muscle fibres of voluntary muscle supplied by the sympathetic non-medullated nerves may be very strongly contracted without gross evidence to a casual eye, but it can be felt. (Compare the rigidity of the rectus abdominis.)

Nobody would advise the performance of a breathing exercise with a half-pound dumb-bell in each hand. Yet the addition of half a pound to the many pounds weight of each arm would not add much to the total weight which the body has to manipulate. The weight of each arm can be realized by holding it out at right angles to the body for a moment or two. If the weights of dumb-bells are gradually increased to a maximum, the full effect of weights (such as the arms) pivoting on the chest can be observed.

The contraction of the arm muscles spreads not only to the supporting groups—those of the legs, back, and abdomen—but to the whole musculature of the body. Even the jaw and facial muscles are involved. So fixed does the thorax become that breathing is entirely suspended, the chest and diaphragm cease to act. The weight of the arms alone has this effect of hampering the respiration, the dumb-bells only intensify it. The weight of the arms is unbearable to anyone in a condition of respiratory distress. Such interference with respiration also impedes the circulation. Neither, when the arms are raised, can any pull occur on the ribs to elevate them, any muscles tending to oppose the raising of the arms being elongated and their tone inhibited (Sherrington's proprioceptive reflex and reciprocal action of antagonistic muscles).

Exercise of the thorax for normal breathing can best be brought about by graduated runs in the open air. After running, if the respiration is left to itself the movements of the thorax and diaphragm will be abundant and natural.

The arms should not be moved. The respiratory muscles and apparatus have been exercised day and night since birth and well know how to breathe. Breathing is entirely self-adjusted and requires nothing more than to be saved from interference.

No artificial exercises, unless a lesion is present, whether they cramp the chest or not, can possibly improve on this self-adjustment possessed by every human being, inherited through many ages. Also, artificial exercises designed to strengthen the muscles of the chest are not breathing exercises. We do not breathe by muscular strength.

Bankart, in his article on physiology of muscular action (*Proceedings* of the Royal Society of Medicine, November, 1925), says, "There is too much arm and leg wagging in the scheme of most gymnasts."

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

COINCIDENT HERPES AND VARICELLA.

THE two following cases, both occurring in the same family, of a definite herpes associated with chicken-pox, are of interest in view of a possible common origin of the two conditions.

The elder child, a boy aged 10 years, on December 21st, 1926, had shooting pains in the right side of the chest, and several raised red spots were noticed by the parents along the line of about the seventh rib. During the following two or three days other spots appeared at intervals over the chest, back, and forehead; there was no complaint of pain.

The younger child, a boy aged 4 years, on January 6th, 1927, had slight malaise, followed the next day by red papules on the chest and back. At intervals on succeeding days others appeared. On examination on the third day of illness there was a typical rash of varicella on the chest and back, showing the vesicles in various stages of development, while on the back of the right hand there was typical herpes over the distribution of the radial nerve to the thumb and first finger. The elder boy then showed the remains of the chicken-pox rash, and in addition several larger scabs along the line of the seventh dorsal nerve, which were the result of the herpes.

It is interesting to note that the herpes and varicella appeared almost at the same time in both cases.

E. E. OUSELEY-SMITH.
Birkenhead. G. WILLIAMSON.

HEREDITARY HAEMORRHAGIC TELANGIECTASIA.

THE following case is reported as one of an unusual hereditary condition of the venules and capillaries of the skin and mucous membranes.

A man, aged 38, came under treatment for advanced pulmonary tuberculosis of some five or six years' duration; he gave a much longer history of recurring epistaxis. He had numerous telangiectases on the lips, which he stated had existed since he was about 15 years of age; they appeared one at a time, but all, he thought, within two years of each other.

Some years later similar spots appeared on the nose and cheeks, and about the same time he noted the same condition on his tongue. Fifteen years ago he began for the first time to be troubled by occasional attacks of epistaxis, which have become much more frequent within the last few years, and were of almost daily recurrence. The spots from time to time became more prominent and more palpably raised, and looked bluer; he thought that this was most frequently observed in the morning, and more especially if he had been drinking the night before. Ordinarily if he cut himself he did not bleed much, but if one of the telangiectases was cut the haemorrhage might continue for hours. Within the last two years he had noted two or three spots on his penis, on the dorsum of the glans.

In addition to the spots noted on the lips and face the patient had a number on the nasal septum, on the anterior two-thirds of the tongue, on the inner aspect of the gums, and on the soft palate. The spots were bright red and, except at certain times, were not palpable. They consisted of a cluster of dilated venules or capillaries, which lay immediately under the surface layer of the epithelium.

The family history is interesting. The patient's grandfather had the same condition, as had also his father and two of his uncles. One sister was also affected, and it had appeared in three cousins; one of the affected cousins died at the age of 28 from a "ruptured vessel in the brain." The patient had seven children—the oldest being 15—but none of them nor any of his sister's children were, so far as he could tell, affected. In all the members of the family in which the condition has been present the onset of the disease was about the age of 15.

C. M. Williams[1] has collected thirty-two cases and added five of his own. The essential features of the cases mentioned by him are the same as in the case here reported—namely (1) the appearance of the telangiectatic spots at puberty; (2) the familial nature of the condition; (3) the marked tendency to haemorrhage; (4) the distribution of the spots especially about the nasal and buccal cavities.

I am indebted to Dr. Elder for allowing me to record this case.

Edinburgh. ERIC C. MEKIE, M.B., Ch.B.

PULMONARY EMBOLISM FOLLOWING CHILDBIRTH.

THE cases reported by Dr. McCulloch and Dr. Young under this title (November 6th, 1926, p. 835) induce me to record two cases in my own experience.

The first was that of a primipara, aged 22, in whom labour had been quite normal; she was attended by the district nurse; I saw the placenta, which was intact. All went well until the fourteenth day, when, as she was getting up (her husband being in the room), she suddenly felt a severe pain in her side and slid down to the floor gasping for breath; her husband said "her face turned blue," and he put her into bed and rushed out to get help. On my arrival I found that he had not exaggerated her condition; she was cyanosed, breathing with difficulty, and evidently in great pain. I could find no sign of disease in lungs, pleura, or heart, and I knew that her history was free from serious disease. I remembered that I had read in the late Dr. Galabin's book an account of pulmonary embolism as a cause of pain, and frequently death, in parturition and child-bed, also a lecture by Professor Briggs on the same subject, so I put a mustard plaster on her side and gave a hypodermic injection of morphine hydrochloride 1/4 grain; she shortly became easier. She was ill for two or three days, and then gradually got better; a thrombosed left femoral vein was found on the day after her sharp attack, which produced a white leg and was treated in the usual manner. She was allowed up at the end of seven weeks and has since had no ill effects. She had no rise of temperature the whole time.

The second case occurred five years ago. The patient was a primipara, aged 19; labour was protracted owing to the size of the child, which weighed 9½ lb. I had to use forceps, and the perineum was lacerated; it was sutured and healed by first intention. She was very restless, and used to shuffle herself about her bed even when I was in the room. The temperature was not raised and all went well up to the eighth day, when I found her normal at my morning visit. In the afternoon I was hurriedly sent for, the messenger saying "that her mother thought that the patient was dying." On arrival I found a similar picture of distress—a "blue patient," gasping for breath and giving instructions to her mother to "take care of the bairn." I had a vivid remembrance of the former case, and gave her a hypodermic injection at once; as soon as she seemed easier I felt for the femorals, but could find no trace of clot, nor did I find any clot on successive days. However, to be on the right side I kept her in bed and gave her citrates. She made an uneventful recovery and has had two more children since. The second child, only 6 lb. in weight, was born without the nurse or myself being called. The third child weighed 8 lb.; delivery was somewhat slow, but otherwise normal. She passed through her lying-in periods without incident.

PERCIVAL HENDERSON, M.D.,
Seghill, Northumberland. L.R.C.P., L.R.C.S.

EXCISION OF PROTRUDING PORTIONS OF THE LIVER.

A YOUNG native man, while celebrating a harvest festival with numerous potations, made an amateur attempt at hari-kari by stabbing himself in the abdomen with a long knife. From this wound, which was directed from above downwards, that portion of the liver which lies towards the left, and beneath the left lower margin of the sternum, protruded to the extent of six inches in length by four inches in breadth.

As the patient had come a long way (three days' journey on foot) it was impossible to think of replacing the gland within the abdominal cavity; three ligatures were passed round the pedicle of the protruding portion of the gland, clip forceps were also fixed at this point, and the entire mass was cut away close to the parietal rent. The abdominal wound healed by first intention, and the patient made an uneventful recovery. The operation was bloodless.

Reports of Societies.

THE ANTITOXIN TREATMENT OF SCARLET FEVER.

AT a joint meeting of the Section for the Study of Disease in Children and the Section of Medicine of the Royal Society of Medicine on February 25th, with Dr. J. D. ROLLESTON (President of the former Section) in the chair, a discussion was held on the antitoxin treatment of scarlet fever.

Dr. E. W. GOODALL, opening the discussion, did not claim to speak authoritatively, but would assume that the haemolytic streptococcus described by the Dicks was the cause of scarlet fever. Clinicians were not so favourably placed with regard to the antitoxin for scarlet fever as were those who had been called upon to express an opinion on antidiphtherial serum thirty-two years previously, for the type of scarlet fever was very mild at the present day, and the case mortality rate had not been above 2 per cent. in London since 1910. There was not much scope for the saving of life by anti-scarlet fever serum, and in addition the septic complications of scarlet fever removed it at once from the pure toxaemias, such as diphtheria. Dr. Goodall said it was difficult to ascertain if antitoxin treatment caused any improvement in case mortality rates even in parts of the world with high rates. In Montreal, for example, a rate of 5 per cent. became lowered to 3.2 per cent. Then convalescent serum was used, and the rate was 2 per cent., and finally, with the introduction of antitoxin, it had become 1.2 per cent. Mostly, however, the efficacy of scarlet fever antitoxin was judged on other grounds. It was found to produce a rapid fall in temperature, disappearance of delirium, fading of rash, and more rapid improvement in the general condition of the patient. Just occasionally cases did not respond. The earlier the serum was given the better the results, and if not employed until the fifth day or later favourable effects were not obtained. Dr. Goodall then dealt with 56 cases in which he had personally employed antitoxin. He pointed out that he had selected his cases, the more severe types receiving serum, and that the number was too small for definite conclusions to be drawn. Four patients died: one from bronchitis, one from septic complications, one from endocarditis, and one from pyaemia occurring in the puerperium. In 35 cases considerable improvement resulted in a couple of days; the bulk of these patients had received antitoxin on the first or second day of the attack. Dr. Goodall had come to the conclusion that a prima facie case had been made out for the efficacy of the serum, and that better results were obtained the earlier it was given. The good results obtained with multivalent antistreptococcal serum in the past were probably due to the fact that such serum contained antitoxin from the scarlet fever organism. With regard to dosage, methods of standardization were uncertain. He usually gave about 50 c.cm. of unconcentrated serum, preferably intramuscularly in one dose. He had had 24 cases of serum sickness in his series.

Dr. R. A. O'BRIEN mentioned reports by fever hospital medical officers outside London. Concentrated serum in doses of 10 to 20 c.cm. had been stated to have a definite beneficial effect in the mild and moderate cases of scarlet fever, but did not seem to touch the septic type of the disease. Serum treatment was thought to be well worth while, and seemed to have an indirect effect on the septic element of the disease, reducing complications. Dr. Rundle of Liverpool had reported the use of serum in 100 toxic cases in which the patients would probably have succumbed without it. Five deaths occurred, all in a group of twenty-five of the septic type. Dr. O'Brien then described five methods of standardization. In the first toxin and antitoxin were mixed until no reaction was obtained in a Dick-positive subject; there was too wide a margin of error in this method. A second method involved the use of goats, but had not received much attention. The third method was to test the amount of antiserum required to blanch the rash of scarlet fever. The fourth method involved determining the quantity of serum necessary to turn a "Dick-positive" person into a "Dick-negative," and keep him so. The fifth method was the outcome of recent work by Parish and Okell, who found that a culture of the scarlet fever streptococcus injected into rabbits killed them in two to three days. Concentrated anti-scarlet fever serum protected these rabbits, and the action was probably specific, although polyvalent antistreptococcal serum protected in 50 per cent. of cases, probably owing to the amount of anti-scarlet fever serum it contained. Dr. O'Brien discussed the polyvalent serum, which many years ago gave good results in scarlet fever cases, and then appeared later on not to be so efficacious. This he believed was due to the fact that whole-broth cultures were at first used for injecting horses, while later washed cultures of streptococci grown on solid media were employed. The broth in the early cases would contain scarlet fever toxin. Lastly, Dr. O'Brien mentioned the close relation of all the haemolytic streptococci to each other. The toxins of the streptococcus responsible for tonsillitis, for puerperal sepsis, and for erysipelas would kill rabbits, but these could be protected by scarlet fever antiserum in percentages far outside any chance result. It was therefore to be hoped that other forms of streptococcal infection might be combated by scarlet fever antitoxin.

Dr. F. FOORD CAIGER said that with the low case mortality of scarlet fever at the present day there could not be much indication of saving of life. He referred to attempts made in the past by pathologists to produce a serum against scarlet fever, and thought that the results of the present day did not greatly exceed the success of the older workers. In particular some work in Warsaw in 1894 with multivalent serum was worth remembering, and it closely anticipated more modern researches. Dr. Caiger inquired if in septic cases there was no other organism responsible; he thought that it was not the Dick streptococcus which was found in the circulation in these cases. It would probably be wise to use multivalent serum in addition in these septic cases. Dr. Caiger finally referred to some serum supplied to him by Besredka thirty-two years previously, which he had used in cases of scarlet fever which he thought would prove fatal. In 44 such cases the mortality was 36 per cent., and he was convinced that the serum was valuable if used early.

The PRESIDENT emphasized the fact that scarlet fever had become progressively milder in type in this country of recent years. He referred to certain figures published in the *Bulletin Internationale d'Hygiène Publique*, which showed that scarlet fever still had a high mortality rate in south-eastern Europe. He agreed that antitoxin should not be given to mild cases, for in addition to the question of expense there was the danger of serum sickness and of a troublesome hypersensitiveness. He had used the serum in a few cases in doses of 10 to 30 or 40 c.cm. He thought that even if serum was used cases could not be discharged earlier without a bacteriological examination of the throat, since some observers had said that the organism persisted for even six weeks.

Sir FREDERICK ANDREWES had been much interested in the "overlap" of antitoxic serum prepared against scarlet fever and other streptococcal infections. It raised the question as to whether there really existed a sharply defined disease which was called scarlet fever. Cases occurring after burns and after operations aroused the gravest doubts as to where streptococcal infection began and scarlet fever left off. The bacteriological evidence presented similar difficulties, since there appeared, from serological evidence in this country, to be three varieties of streptococci found in the throats of scarlet fever patients. It was probable that different races of streptococci produced the same common toxin, as occurred in the case of the tetanus and diphtheria organisms.

Dr. A. JOE compared his experience in Edinburgh and in London, emphasizing the mild nature of the disease in the south. He had not seen one septic case in five months in London, and, on the other hand, serum sickness had been much more troublesome. He referred to the use of the older multivalent serums, and pointed out that blanching of the rash in scarlet fever had been obtained with such serums in pre-Dick days. He agreed as to the "overlapping" of the streptococcal serums.

Dr. J. McCARTNEY mentioned the difficulties associated with examining throats for organisms before discharge of scarlet fever patients. He also had observed the "overlapping" of the streptococci. He thought that much could be learnt by studying the organisms responsible for the cases in which anti-scarlet fever serum failed to produce any effect.

Dr. E. J. PARISH referred to his experiments with rabbits injected with scarlet fever toxin intravenously. Toxins from the organisms causing erysipelas and puerperal fever had not given such satisfactory results. After neutralization of the scarlet fever toxin by injections of antiserum the rabbits nearly all developed joint lesions with pus formation later. Haemolytic streptococci were obtained from this pus. In the rabbits injected with puerperal toxin joint lesions occurred earlier.

TREATMENT OF CANCER OF THE BLADDER.

MEETING of the Urological Section of the Royal Society f Medicine was held on February 24th, with the President, r. W. GIRLING BALL, in the chair; Mr. HENRY WADE Edinburgh) read a paper on the treatment of malignant isease of the bladder.

Mr. Wade, in a preliminary survey of the surgical treatent of carcinoma elsewhere in the body, deduced certain rinciples which he considered should be applied to the reatment of malignant disease occurring in the bladder. le deplored the failure of radium and deep *x*-ray therapy, nd insisted that at present the only rational line of attack as by means of the knife. The ideal was excision of the rowth with as much of the surrounding tissue as possible. t was not always possible to estimate with any degree f accuracy the size and extent of the growth during the reliminary examination of the patient. Frequently when bladder was opened carcinoma was found to extend urther than had been suspected by cystoscopic examinaion. Moreover, histological examination of excised papillomata often showed that what had appeared clinically to be n innocent growth contained an area of malignancy at its ase. This did not, however, necessarily mean that treatnent of such papillomata by diathermy would fail. The esson to be drawn from the observation was rather that n dealing with papillomata, whether by diathermy or by xcision, the treatment must be exceedingly thorough if recurrence was to be avoided. Mr. Jocelyn Swann had shown in his presidential address to the Section that no sharp line could be drawn between non-malignant and malignant growths of the bladder, and for this reason innocent growths should be treated by free excision where possible, as though they contained elements of malignancy. In this procedure resection of the ureter was a common necessity and presented no particular difficulties. It was indeed surprising how rapidly a mutilated bladder recovered, and how soon the remaining portion compensated for what had been lost. A more difficult question to decide was the treatment of malignant disease of the bladder of such an extent that removal required the transplantation of both ureters. Many surgeons thought that total cystectomy was unjustifiable; he, however, believed that this operation had a very definite place in genito-urinary surgery. Before removing the bladder it was necessary to make provision for removing the urine by transplantation of the ureters, either into the bowel or to the surface. Work at the Mayo Clinic had shown that if both ureters were transplanted into the bowel at the same operation there was some danger of suppression of urine caused by post-operative oedema at the site of operation. It was seldom possible, however, in the case of malignant disease of the bladder to carry out transplantation in two stages, since the patient was in a precarious condition and time an all-important consideration. In his own cases Mr. Wade had brought the ureters to the surface of the abdomen and had relied on various mechanical devices for keeping the patient dry. In achieving this the chief difficulty arose from the fact that an appliance which kept the patients dry when standing generally failed when the patient assumed a sitting or recumbent posture. Much ingenuity had been exercised in attempting to overcome this difficulty, but the ideal method of collecting urine from a ureter implanted on the surface of the body had yet to be found. The operation of total cystectomy presented very few technical difficulties once the ureters had been satisfactorily transplanted. In the four cases in which he had employed it he had removed the prostate and vesicles as well as the whole of the bladder, since he had found that it was easier to include these structures than to leave them behind. Moreover, it not infrequently happened that growths in the bladder extended into the prostate. Of the four patients treated by total cystectomy two were still alive, and two had lived for a period of two years. Even though the operation had not been curative in these two patients their end had been far more comfortable than if no operation had been performed. For this reason he believed that total cystectomy was justified even when the extent of the growth was such that a complete cure was unlikely or impossible. In conclusion, Mr. Wade said that he was aware that he might be accused of holding heroic views on the subject of total cystectomy when he urged that it should be employed, not only in cases in which there was a reasonable hope of extirpating the growth, but also in those in which this was clearly impossible. No one, however, could view the sufferings of a patient dying from malignant disease of the bladder and the failure of all palliative measures to mitigate these without being prepared to go to any length in his attempt to find a remedy. The technique of total cystectomy was capable of great improvement, and he could foresee the time when with improved methods surgeons would carry out total removal of the bladder as a routine measure. He could even imagine the operation being resorted to either as a palliative proceeding in inoperable cases or as a measure of security in those cases which at present were dealt with by subtotal excision.

In the ensuing discussion the following took part: Mr. GIRLING BALL, Mr. SWIFT JOLY, Mr. KENNETH WALKER, Mr. CYRIL NITCH, Mr. MORSON, Mr. MACALPINE, Mr. FOWLER WARD, and Mr. R. OGIER WARD.

ORAL SEPSIS AND SKIN DISEASE.

AT a meeting of the Section of Odontology of the Royal Society of Medicine on February 28th, Dr. H. W. BARBER read a paper on the relationship of dental infection to diseases of the skin, discussing the subject under two heads: (1) the coincident surface infection of the skin and of the oral and naso-pharyngeal mucous membranes, and (2) the secondary effects of such infection upon other organs of the body—that is, focal sepsis and its results.

Both the skin and the oral mucous membrane had, he said, what might be regarded as a natural flora of microbial organisms, but in health the various species of organisms occurred as isolated units, not in a state of active growth; they were, therefore, saprophytic, not parasitic. Under certain conditions they took on active growth, invaded the tissues of the host, thus becoming parasitic, and (to a varying degree, according to the species) pathogenic. In the skin the common organisms were the "bottle-bacillus" (probably a yeast), which grew in the horny layer, producing dandruff; the acne bacillus, which flourished in the pilo-sebaceous follicles; and staphylococci, particularly *Staphylococcus albus*. In the oral mucous membranes the most important were various strains of streptococcus. Dr. Barber suggested that the underlying conditions which favoured the active growth of these different species of organisms in the skin and mouth were metabolic or biochemical in origin. As regards the skin, seborrhoea—or rather the seborrhoeic state, of which seborrhoea was one of the manifestations—predisposed to the active growth of these three types of organisms. This state was an index of faulty metabolism, apparently associated with the excessive formation and inadequate excretion of acids of the fatty-acid series. It was presumably the excretion of these acids through the sebaceous and sweat glands, and probably through the skin as a whole, that favoured the active growth of organisms which were either not present, or existed as isolated units only on normal skin. The chief etiological factors considered to be responsible for the seborrhoeic state were: (*a*) heredity, (*b*) diet, (*c*) faulty

hygiene—for example, insufficient muscular exercise, lack of fresh air, excessive clothing, insufficient fluid intake—(*d*) the stresses of sexual evolution. Of these the most important were (*b*) and (*c*), particularly a want of correlation between diet and physical exercise. Excessive intake of carbohydrate, especially of soft fermentable starchy foods and concentrated sweetstuffs, and, to a less extent, of fats, was the chief dietetic error responsible, combined with an insufficient intake of fresh vegetables and fruit. The same dietetic faults were also held largely responsible for the active growth of micro-organisms in the mucous membranes of the mouth and naso-pharynx, and the invasion of the tissues by them, and clinically a liability to seborrhoeic infections of the skin was found to be associated with a similar low resistance to infection of these mucous membranes, resulting in dental caries, gingivitis, pyorrhoea, and naso-pharyngeal catarrh. Dr. Barber therefore suggested that measures ought to be taken, in the interests of national health, to reverse the present economic policy as regards foodstuffs, which, on the whole, rendered the most harmful articles of diet the cheapest, whereas fresh fruit and green vegetables were relatively among the dearest.

Once active microbial invasion of the tissues had taken place there resulted, not only the local, but also the remote, effects of such invasion, owing to the absorption of toxins or the escape of micro-organisms into the lymphatics and blood stream. The most important pathogenic organisms concerned in so-called focal infection or sepsis and its secondary complications belonged to the streptococcal group. With regard to oral sepsis, the effects of gingivitis, pyorrhoea alveolaris, and apical infection had to be considered. Of these probably the last was the most potent as a cause of systemic disease. The diseases of the skin which might be caused directly or indirectly by oral sepsis could be classified as follows:

1. Diseases due to direct spread of infection from the oral mucous membrane to the skin—for example, impetigo contagiosa, streptococcal fissure, perlèche, and relapsing streptococcal lymphangitis.
2. Diseases in which oral sepsis by its effect on the digestive processes, by setting up an infective gastritis and by causing a secondary infection of the intestinal tract with acid-producing organisms (such as streptococci), thus favouring fermentation, might play a causative part—for example, rosacea.
3. Diseases in which the presence of an infective focus in the mouth lowered the resistance of the patient to pyogenic infection of the skin—for example, boils.
4. Diseases in which the epidermis became sensitized to toxins absorbed from the mouth and teeth—for example, eczema.
5. Diseases which might be regarded as true anaphylactic reactions due to systemic sensitization to bacterial protein—for example, urticaria, angio-neurotic oedema, certain mixed erythemato-urticarial eruptions.
6. Diseases in which the toxins from an infective focus acted on the nervous or endocrine-sympathetic systems, the changes in the skin being secondary to such involvement—for example, herpes zoster, alopecia areata, vitiligo, scleroderma, Raynaud's disease, and some forms of prurigo.
7. Diseases due to inflammatory reactions produced in the skin as the result of bacterial embolism in the dermic or subcutaneous vessels, or by the action of bacterial toxins carried to the skin in the blood stream—for example, erythema multiforme, erythema nodosum, lupus erythematosus.

Professor J. W. EYRE said that seeing, as he did, the results of treatment instituted by Dr. Barber, where so much of the primary sensitization had been due to some bacterial source, he had been impressed by the close association between sepsis in the mouth and these skin lesions. Dr. Barber did not speak of sepsis attacking a live tooth and being a cause of skin disease; it was a kind of superstition that living teeth could not have apical suppuration associated with them, but many of the cases they had seen together showed this to be a fallacy. In most instances of skin affections the bacterial side could be divided into one of two groups: the patient had either oral sepsis or intestinal sepsis, and the latter might be secondary to the former. Thus the conclusion was enforced that the dental surgeon played the biggest part in preserving the nation as a whole from skin diseases. He agreed with practically all Dr. Barber said.

Mr. A. T. PITTS suggested that there was considerable doubt about the apical lesions of which Dr. Barber spoke so certainly; the dental profession was still much in the dark as to their nature. The *x* rays had shown that areas of apical rarefaction were very common, and it was usual for medical men to refer to them as abscesses. He asked whether it was safe to assume that all these apical conditions were such pathological constants as they were assumed to be. Sometimes the same appearances were observed in connexion with living teeth, but radiological technique might be defective. In some of those cases abscesses were found, in others masses of granulation. The granuloma might not be so much an evidence of infection as something in the nature of quarantine, thrown up by the body as a defence against infection in the tooth.

Mr. J. G. TURNER asked whether it was contended that a healthy person did not suffer from skin disease. He did not see the force of associating seborrhoea with dental disease, seeing that the latter might start in earliest childhood. The question of dental disease in Britain seemed to be summed up in the fact that we ate bread. With regard to the question of calcium deficiency, most people who were supposed to have this deficiency had ample quantity of tartar on their teeth. Decomposin food was always to be found in close association wi ordinary teeth, and this decomposing product must eith be swallowed or absorbed, and so was a possible source detriment to health. He also asked what was the value reflex irritation as a cause of skin manifestation.

Dr. E. W. FISH said one would imagine that sensitizati of the skin would take place as easily from a carious too as from an apical abscess. He saw no reason why t toxins from a carious cavity should not be absorbed the lymph stream from the dentine of a tooth which w normal except for the caries. He would be interested a further exploration of the association of dental cari with skin diseases. In both apical abscesses and dent caries it was a question of ulceration of epidermal tissue and when the ultimate pathology of skin disease and th of dental caries had been fully worked out it was like there would prove to be many points of similarity. present there was somewhat of an obsession that t causation of dental caries was purely saprophytic.

Mr. F. N. DOUBLEDAY spoke of the possibility of the bo being a source of skin and other troubles in patients w were edentulous. Sometimes if bone was cut down upo in the areas which *x* rays showed were rarefied it woul yield a pure growth of streptococcus.

Mr. W. A. BULLEID said he had seen many of the patien referred to in Dr. Barber's paper, and he was able to spea of the remarkable results which had ensued from a com bination of the efforts of the dental surgeon, the dermat logist, and the bacteriologist. The most satisfactory result seemed to have been achieved in cases in which the infe tion was of the closed type, rather than the open. Usuall one was quite safe in condemning apical sepsis as bein responsible for some systemic disturbance in the patien He mentioned a remarkable case of urticaria of ten years standing, the patient being a woman 45 years of age, with in addition, hypertrophic gingivitis. A pure culture o *Streptococcus viridans* was obtained. Following treat ment, the urticaria disappeared for four months. When i returned, cultures having been kept of the case, she wa vaccinated. That took place six years ago, and there ha never since been any return of the trouble.

Dr. BARBER, in reply, said that Professor Eyre and h had had many cases together in which not the teeth but th tonsils, the naso-pharynx, or the sinuses were the seats o the septic trouble. He had an objection to advisin removal of people's teeth if there was any means of con serving them, for, however skilful the dental surgeon migh be, there was something definitely lacking about a plate Even with all the aid now given by *x* rays the problem wa not always solved. In answer to Mr. Turner, he (th speaker) did not mean to contend that everybody who ha dental decay or dental sepsis was necessarily seborrhoeic what he meant was that the lowered resistance to infection in the mouth very often caused a lowered resistance i the skin too, and vice versa. He could scarcely recall patient with really bad chronic seborrhoea who had not als

a severe infection of the mouth, and dental decay from early years. With regard to the bearing of calcium deficiency on the problem, he remembered a remark made by one of the Mayo brothers when in this country, to the effect that it would be found that practically the whole of medicine would be found to be a question of calcium metabolism. He had himself been investigating a number of cases from that standpoint, and with very interesting results. The recent or mild cases of seborrhoea did not usually show any calcium deficiency. He thought it quite possible that absorption of toxins could take place from carious teeth, but he had no experimental evidence to support it. Infection from dental plates was probably a question of the person swallowing the material and setting up a focal infection in the intestine secondarily.

DISEASES CARRIED BY MILK.

AT a meeting of the Section of Comparative Medicine of the Royal Society of Medicine on February 23rd, with the President, Sir D'ARCY POWER, in the chair, Mr. G. P. MALE read a paper on cow's milk as a factor in the transmission of certain diseases to man (excluding tuberculosis).

Mr. Male said he did not propose dealing with all the diseases which might be contracted by man as a result of drinking cow's milk. The danger from tuberculosis was so thoroughly established that there was now no doubt of its seriousness, but many other diseases were not so well demonstrated, and there was still room for further investigations. Now that the Milk and Dairies Consolidation Act (1915) was in operation the subject was of importance to both medical and veterinary practitioners. The powers conferred on medical men to stop the supply of milk from suspected dairies was not confined to tuberculosis, but also included acute mastitis, anthrax, foot-and-mouth disease, actinomycosis of the udder, any comatose condition, and septic condition of the udder or teats which might cause disease. The Milk and Dairies Order of 1926 required notification of any infectious disease in persons engaged in handling milk. Veterinary surgeons were required also to examine cows to ascertain whether any disease liable to infect man was present. Unfortunately this inspection had not been made universal, and so some of the benefits of the Act were lost.

Anthrax was usually so fatal that the bacilli were as a rule not present in the milk before death. Sometimes, however, animals did not die from the disease, and so fever in cows should cause careful observation of such animals to be made. Very few deaths had been recorded from anthrax conveyed by milk, but dangers from this source did exist.

Actinomycosis of the udder was relatively rare, and could often cause infections.

Foot-and-mouth disease, though common in this country, had only rarely been reported as affecting man here. Many outbreaks had been reported from the Continent, however, from infected milk.

Acute mastitis and suppuration of the udder were conditions which should always cause the withdrawal of milk. There was, however, great difference of opinion as to the pathogenicity to man of many of the organisms found in less severe cases. Streptococci were the most frequent organisms found, although others were also implicated; and in this way septic sore throat, scarlet fever, and other conditions had been traced to disease in cattle. There seemed to be general agreement that it had yet to be proved that the common streptococci found in milk were the same as those causing septic sore throat. The causal organism, however, of this condition might be carried passively by the milk from one person to another.

Cow-pox was very common in Britain. This eruptive disease affected chiefly the teats and udder, the general health of the cow being usually unaffected. Eruptions formed locally, became elliptical vesicles, which about the tenth day matured and became pustules. These fell off in about three weeks and left a scar. These might become infected with secondary organisms, and the primary changes, not having been noticed, confusion with other conditions might result. The disease was easily transmitted to man, and Mr. Male had seen severe eruptions due to this cause, in some cases leading to septicaemia. Children were sometimes infected by drinking milk, but without serious results.

Contagious abortion was very common in this country, and after abortion the organisms appeared in the milk. The organism had recently been shown to be closely related to that causing Mediterranean fever, and it had been found in several human cases. It had also been suggested that it might cause abortion in women; personally, Mr. Male thought that the bacillus was not pathogenic for the human female.

Many different diseases of human origin were carried by milk, but he proposed only dealing with two—diphtheria and scarlet fever.

Diphtheria had in several cases been reported from milk in circumstances which (it had been suggested) implicated the cow as an actual carrier. The organism, however, was very common in healthy carriers, and Mr. Male thought that this fact had not been taken into consideration when those investigations had been made. In one outbreak investigated by him the cow had been suspected, and he found that she had been suffering from cow-pox, and that the organisms had come from a human carrier. Although it was possible that the organism could live in sores in cows' teats, there was no disease caused by the Klebs-Loeffler bacillus existing in cattle.

Scarlet fever was in a similar position. The disease was not uncommonly spread by milk, but proof was lacking that the organisms ever originated in the cow.

With the extra facilities given by the Milk and Dairies Acts and Orders, with the improvement in methods of sterilizing or pasteurizing milk which enabled the medical officer to stop or sterilize the supply at the first sign of disease, and with the rapid improvement in methods of handling and producing milk, Mr. Male believed that the menace to human health from that source would soon be considerably lessened and ultimately eliminated.

Professor WOOLDRIDGE recalled an instance of eight people drinking milk for several days from a cow which proved to be suffering from a streptococcal mastitis all the time. None showed any symptoms at all. Foot-and-mouth disease might, he thought, be conveyed by milk, especially in the early stages of the disease when the infection was present in the blood. Mr. PUGH said that a month ago he had drunk a glass of milk from a cow which a few hours later died from anthrax. He had antiserum administered and his stomach and rectum were irrigated with creosote solution within forty-eight hours. A week later he suffered from a rash due to the serum. He was only now recovering from the effects of an anaphylactic shock due to eating a beef sandwich.

Dr. H. H. SCOTT mentioned that several cases of undulant fever had been reported from districts in Italy where the caprine organism was absent.

Mr. DALLING pointed out that he had found the bacillus of diphtheria in sores on horses, and that it could live in similar sores on the udders and teats of cattle, and in this way enter the milk.

Dr. T. CAMERON stated that a peculiar set of outbreaks had recently been reported from France. Children had developed a series of symptoms of a gastro-intestinal nature, and in every case, within forty-eight hours, foot-and-mouth disease had occurred in the cow from which the milk had come. This had occurred so frequently and so regularly that there was little doubt that Professor Wooldridge's suggestion was correct—namely, that the milk was infective before the appearance of symptoms in the cow. Dr. Cameron suggested a possible explanation of the relative immunity of persons in this country to the disease. There were two strains of foot-and-mouth disease; (*a*) from Germany mainly (the region where most of the human outbreaks had occurred), and (*b*) from France. It had been shown that the latter was far more common in this country than the (*a*) strain, and he suggested that it might prove that only one strain—the (*a*) strain—was infective to man. There were, of course, a few human cases in Britain, but none had proved serious.

ORGANIZATION OF A FACTORY CLINIC.

AT a meeting of the Section of Epidemiology of the Royal Society of Medicine, on February 25th, a description of the ideal factory clinic was given by Dr. N. HOWARD MUMMERY. It was based upon a clinic actually in existence in the largest industrial establishment of its kind in this country.

The factory clinic, Dr. Mummery said, must be considered to be part of the "welfare" department, and its medical officer should be an expert adviser to the superintendent

of that department; he should not be an administrative or executive official. The premises for the clinic should be in the factory itself, preferably on the ground floor, and should include a waiting-room, first-aid surgery, and doctor's consulting-room equipped with the necessary appliances for a thorough examination. Other rooms which might conveniently be situated in the same block were a dental surgery, a rest and recovery room, and rooms for massage and manicure and pedicure. A house telephone system was essential, and in a large establishment a motor ambulance was very useful. The extent of the factory would determine the size of the clinic staff, and whether the medical officer and the dental officer should give whole-time or part-time service. A weekly visit from an ophthalmic surgeon enabled employees to be examined for errors of refraction, and another useful service was that of a trained masseuse with knowledge of the simpler forms of galvanic and high-frequency treatment, working under the factory doctor's supervision. A sufficient number of trained nurses should be employed to ensure that one at least was always on duty day and night during working hours. Dr. Mummery gave a long list of the uses of such a clinic: immediate treatment of minor injuries, and first-aid treatment in major accidents; diagnosis and treatment of minor illnesses and of medical emergencies; after-care and remedial treatment of operation cases and serious injuries with impaired function; recommendations as to change of occupation or light duty; medical examination of applicants for employment, including some vocational selection; examination of workers returning after illness or disablement; periodic re-examination of young or under-developed workers, and of those exposed to special occupational risks; domiciliary visiting of sick and injured employees; the establishment of co-operation with hospitals and private and insurance practitioners; general advice to the management and to individual workers on health questions and on the lighting and general sanitation of the premises, and, finally, the keeping of records concerning the health of the staff and the incidence of disease and accident. Great economy of time could be effected by treating at the factory all injuries not involving absence from work, and many of those causing temporary incapacity, as well as cases of skin disorders. He had found that the various skin eruptions common among industrial workers—seborrhoea, tinea, and the like—were slow in recovering under ordinary methods of treatment until a "skin corner" was started in the clinic surgery where patients could sit, under the nurse's observation, and for ten minutes at a time rub in simple preparations. The building and equipment of the clinic should be a capital charge on the firm, and maintenance costs and salaries of the clinic should be shown in the accounts of the whole "welfare" department of which it was a part. On the credit side must be entered the cash results of the saving of working time, lessened absenteeism, and other values not readily translatable into figures. Dr. Mummery gave some records from the clinic. One of these showed how the incidence of accidents corresponded with the speed of production; a speeding up of 10 per cent. resulted in an increase of accidents equivalent to from 50 to 100 per cent., an indication, of course, not of fatigue, but simply of increased and unaccustomed working activity; the accident rate varied inversely with the experience of the workers. He also quoted some statistics relating to the recent influenza epidemic. The staff at the factory numbered just upon 6,000, and of this number during January—the most severe period of the epidemic—329 employees were absent owing to this cause. Of these, 92 were away from one to six days, 171 from seven to fourteen days, and 66 for more than fourteen days, while 4 relapsed and had to take further leave. The attendances at the clinic during 1926 numbered 37,139, of which minor injuries accounted for 11,444, illness for 5,566, dental treatment for 3,376, massage treatment for 2,258, and medical examinations for prospective employment 2,689. He recalled Mr. Warren Low's recent presidential address to the Section of Surgery in which he had said, dealing with the subject of workmen's compensation, that another kind of hospital was needed, or, more properly, an after-care industrial centre, where, by constant personal supervision and encouragement, men who had suffered from injury or illness might be induced to overcome their diffidence with regard to their returning powers. That was exactly the work that he and others had for years past been trying to do in factory clinics.

VACCINE THERAPY.

AT a meeting of the Medico-Chirurgical Society of Edinburgh on February 2nd in the Scottish House of the British Medical Association, with Professor RUSSELL in the chair, a discussion on vaccine therapy was introduced by Dr. GLEN LISTON.

Dr. Liston said that, in spite of the fact that vaccines for the prevention and treatment of disease had been before the profession for more than a quarter of a century, there were still some who hesitated to use them. On the other hand, others treated all manner of ailments by vaccines. The cause of this divergence in practice was probably due to the absence of any systematic instruction in vaccine therapy. There was also generally a lack of co-operation between the clinician and the bacteriologist. The efficiency of vaccine therapy could be estimated in three ways, the first being examination of the immunological response produced by injecting a particular vaccine into a healthy man or animal. The second way was to inject the vaccine prophylactically into men and animals, and, in the case of men, after exposure to infection making a statistical inquiry comparing the progress of the disease among the inoculated and uninoculated respectively. In the case of animals resistance to infection was tested by injecting into them graduated doses of a virulent culture of the organism used in preparing the vaccine, and comparing the mortality among the vaccinated with the mortality among untreated animals injected with the same dose. Efficiency could also be estimated by employing a vaccine in the treatment of specific infections, and observing the rate of recovery in these cases when compared with untreated cases. Certain fundamental principles governed the practice of vaccine therapy. A vaccine must be made from a particular species of organism which had been ascertained to be the cause of the disease under consideration. It must be so prepared that when injected into an animal it would stimulate the tissues to produce substances and mechanisms antagonistic to the living microbe. The general principles of the dose of vaccine to be used for the prevention and the treatment of a disease must be thoroughly understood and mastered. In treating a disease by a vaccine the way in which micro-organisms protected themselves against destruction in the tissues, especially in an ecphylactic nidus, must be understood and suitably countered. It must be recognized that vaccine therapy had definite limitations, which could not be overcome by inventing new vaccines or special antigens. Vaccine therapy would always have its chief and most successful application in the treatment of disease, in the treatment of local infections, and in the earlier stages of acute infections. In the later stages of acute infections immuno-transfusion possibly afforded some prospect of success.

In the discussion which followed much emphasis was laid on the importance of care in the collection of specimens, and also on the value of co-operation between the clinician and the bacteriologist. Several speakers referred to the varying results in vaccine therapy. Prophylactic inoculation was generally considered the more satisfactory, but many disappointments were confessed in therapeutics.

Ague in Scotland in the Past.

Dr. JAMES RITCHIE (Royal Scottish Museum), in a communication on the former occurrence of ague in Scotland, said that while the distribution of ague in England had been investigated in detail, this was not so in Scotland. It could be shown that in early days, as late as the middle of the eighteenth century, ague was a common and widely spread disease, affecting most severely the agricultural section of the populace, and interfering with their activities. Examinations of old hospital records indicated that the disease was endemic. By the middle of the nineteenth century native ague was almost unknown. The diet which was available for man and beast in certain

districts of Scotland at that time was very restricted. Turnips and such foods were not grown, and so the winter food was very deficient. In the spring the farmers gathered at one farm and helped to move the cattle to the pasture. Some of the cattle might have to be lifted owing to their weak state. The conditions, therefore, for man were very poor, and infection by the mosquito was very likely. The mosquito found ideal conditions for hibernation in the heated farmhouses, and became active in the early months of the year. Thus it was found that ague occurred in the spring.

Dr. GLEN LISTON referred to another explanation of the peculiar seasonal prevalence of malaria in spring in this country. There were three types of anopheles—*maculipennis, bifurcatus,* and *plumbius*. *Anopheles maculipennis* passed the winter as an adult in places where animals lived, obtaining warmth and food by continually sucking blood. In the spring, therefore, they were ready to transmit malaria to the uninfected. Dr. ANGUS MACDONALD said that a temperature of 60° was necessary for plasmodial development and the passing of malaria to man. The temperature records showed that a period of high temperature was associated with an epidemic of malaria.

HISTORY OF MEDICINE IN EUROPE.

AT a meeting of the Devon and Exeter Medico-Chirurgical Society on February 17th, Dr. R. EAGER in the chair, Dr. WILLIAM GORDON read a paper entitled "The periods of European medicine: a study of the reaction of an intellectual industry to variations in its environment." In view of the general interest of the subject members of the Historical Society of Exeter were present by invitation.

Dr. Gordon defined three main periods—namely, (1) the rise, from the first recorded Greek medical discoveries about 600 B.C. to the death of Galen in 202 A.D.; (2) the pause, from the death of Galen to the beginning of the sixteenth century; and (3) the reascent, from the beginning of the sixteenth century to the present day. In each of these periods he distinguished three subperiods. The rise included a pan-Hellenic subperiod from about 600 B.C. to the establishment of the first recorded school of human anatomy at Alexandria about 300 B.C.; an Alexandrian subperiod from that date to the establishment of Greek medicine at Rome by Asclepiades about 91 B.C.; and a Roman subperiod from then to the death of Galen. The pause began with an interval of chaos following the murder of Commodus, and might be held to last, as far as medicine was concerned, for about a century and a half, until the writings of Oribasius, the first Byzantine writer. This was treated not as a subperiod but as a "gap." The first subperiod of the pause was the Byzantine and Persian subperiod, the Byzantine portion beginning with the foundation of Constantinople and closing in the eighth century, when its important writings ceased, while the Persian portion dated from the establishment by the exiled Nestorians in the fifth century of the school of Jondisabur, which in the eighth century became the starting point of Arabic medicine. The second subperiod of the pause was the "Arabic," beginning with the translators of the eighth century and maintaining its vigour until the middle of the thirteenth century, thus somewhat overlapping its successor. The third subperiod of the pause was "The age of pointed architecture," the only title which sufficiently defined the thirteenth, fourteenth, and fifteenth centuries, of which it was composed. The reascent period contained a north Italian subperiod lasting about a century, the workers living round Padua; a "trans-European" subperiod of about two and a half centuries, so named from the workers extending over an area comprising Italy, Switzerland, France, the Rhineland countries, and the British Isles; and a pancosmic subperiod from 1840 to the present day, in which the title was justified by the distribution of the workers. The points to which attention was chiefly directed were: the liberty of thought, to which medicine seemed to be even more sensitive than art and letters; the lateness of medicine to mature in each succeeding civilization as compared with art and letters; the curious movement polewards of the main seats of medical activity during the march of time—a movement shared by other evidences of human energy; and the influence of nationality.

Professor HART expressed the appreciation of the Historical Society, and noted with interest that many persons whose names were found in the science of medicine had also won honour in other fields, as for example, Aristotle and Rabelais. He had observed through the lecture that; whereas medical lore had been ripe along the Nile, sterility had seemed to have been the case along the Euphrates.

Dr. JONAS remarked that submission to authority had often proved a deterrent in medicine, and he gave as an example the era controlled by Galen. Conversely, progress in Great Britain had resulted from freedom of thought. Dr. Jonas added that at the time of Susrata India was far in advance of Greece, and in allusion to the skill of Susrata quoted his aphorism, "The best instrument is the hand of the surgeon."

Dr. GORDON, in his reply, said that the medical profession had indulgence and liberty in Egypt, and the science of medicine was treated with dignity and honour. On the other hand, in Babylonia medicine flourished empirically, and punishment followed failure in treatment on the lines of the code "an eye for an eye." Herodotus had stated that there were no physicians in Babylon, and that the sick were exhibited in the street with the hope that those passing by might be able to offer suggestions in diagnosis and treatment. With regard to the small part played by India in the diffusion of knowledge, Dr. Gordon said that the position held by India in the pioneer period of medicine must be acknowledged, but unfortunately that position had been isolated, and had been of negative value to the world at that time owing to lack of communications.

Mr. RUSSELL COOMBE, alluding to the discoveries in Mesopotamia, said that further investigation would show some day that medicine there had not fallen short of the high grade of civilization in that country in ancient times.

JAMES MACKENZIE INSTITUTE.

ON February 15th, at the James Mackenzie Institute for Clinical Research, St. Andrews, Dr. MCKERROW read a paper on skin hyperalgesia in abdominal disease. He pointed out that this symptom was almost entirely ignored in surgical textbooks, although Mackenzie, Head, Sherren, Hurst, Cope, Ligat, and others had demonstrated its importance. Mackenzie was among the first to realize the value of this viscero-sensory reflex in localizing abdominal disease, and to point out that if the reflex path was traced back to its origin it would lead us inevitably to the organ at fault, since the hyperalgesic skin received its nerve supply from the same segment of the cord as the diseased viscus causing it. Ligat's work was fully reviewed, and the lecturer quoted several cases supporting Ligat's findings. It was obvious, he said, that the circumscribed areas figured by Ligat would be enlarged in cases complicated by extension of inflammation to the subperitoneal tissue, which was richly endowed with cerebro-spinal nerves; this probably explained, in part at least, the difference in shape and size of hyperalgesic areas figured by Cope and Ligat. As regards the adequate stimulus required to induce pain and hyperalgesia, Mackenzie held that since mechanical stimuli such as heat, cutting, etc., produced no sensation when applied to viscera supplied from the sympathetic system, the adequate stimulus must be provided by a vital activity, and he considered that abnormal contraction of non-striped muscle was the source of this stimulus. Other authors suggested increased tension or imperfect drainage of the tissues as the cause, but the lecturer pointed out that tension and obstruction were just the conditions that led to overactivity of the muscular coat. Ligat's view that the mucosa contained the receptors for the viscero-sensory reflex was capable of a similar explanation, since stimulation of the mucosa resulted in peristaltic activity. He drew attention to the cases quoted by Ligat, which showed that the area of hyperalgesia was constant no matter what displacement of the related viscus was present. He concluded that Ligat's contention that "in a typical case the hyperalgesic area found accurately indicates the organ at fault" was true and of great diagnostic value.

Reviews.

PSYCHOLOGY AND ETHNOLOGY.

IT was the wish of the late Dr. RIVERS that certain of his memoirs on ethnological subjects which were scattered in volumes not readily accessible to students should be collected into a book. In fulfilment of a promise that this should be done, Professor ELLIOT SMITH has chosen a number of essays, including some hitherto unpublished, and has issued them together under the title of *Psychology and Ethnology*.[1] The result is a volume every page of which is of great interest, and although the subject-matter of the selected articles is very diverse, one fundamental idea, which was ever present with Dr. Rivers, is evident throughout—namely, that the essential aim of ethnology should be to ascertain the psychological motives which impelled men to develop customs in different ways. The book is prefaced with a useful introductory chapter in which Professor Elliot Smith describes the gradual development of Dr. Rivers's ideas in ethnology, their relation to current theories, and his contribution to the advance of the science.

An early conviction of Rivers that psychology and ethnology were better studied apart was due apparently to the comparative lack of concrete data afforded by the former science. It was probably the influence of this conviction which led him to accept, in the first instance, the doctrine of Tylor and Bastian that, when the conditions are similar, similar customs and institutions come into existence and develop on the same lines among peoples that may be widely separated both geographically and ethnologically. That this crude evolutionary doctrine was insufficient became obvious to Rivers during the preparation of his work on Melanesian society, in 1914, and his attention was thus drawn to the study of ethnological method. In this study he was struck by the fact that whereas in other sciences research, in whatever country it might be conducted, had identical principles and methods, in anthropology the divergence of method in different countries was so great that any common scheme was impossible. For instance, many transitional forms of design used in the artistic work of different races, which British anthropologists would have described as representing stages *in an evolutionary process*, were, by the modern German school, ascribed to a mixture of cultures and of peoples. Hence Rivers arrived at the belief that evolutionary speculations were valueless apart from a preliminary analysis of the cultures now spread over the earth's surface, such as would ensure the detection of elements of the more advanced cultures in the institutions of apparently primitive peoples. This change of view involved the admission of the reality of cultural diffusion, although Rivers's attention became focused rather upon the effects of the admixture of cultures. It was also evident that in tracing the source of cultural elements a knowledge of the different motives actuating different peoples would be of great value, and that the study of the psychology of motives was an essential part of ethnology. Thus the barrier between Rivers's psychological and *ethnological studies* was broken down and the two became intimately blended. As regards psycho-analysis, Rivers gave a qualified assent to its main principles, while dissenting from the Freudian speculations in ethnology.

The ultimate influence of Rivers's work will, in the opinion of Professor Elliot Smith, be to bring back anthropology into conformity with the sound principles enunciated by Sir Edward Tylor, by relighting the lamp of history. "To ingenious attempts at explaining by the light of reason things that want the light of history to show their meaning, much of the learned nonsense of the world has indeed been due."

AEROPHAGY.

DR. G. LEVEN'S book on *L'Aérophagie*,[2] first published about seven years ago, and then noticed in this JOURNAL (1920, ii, 794), is a clinical, radiological, and therapeutical study of air swallowing, a common condition which is of some importance because troublesome and even serious. It has now been revised and expanded in a well deserved second edition. If, when air is swallowed, the cardiac end of the oesophagus remains closed it is noisily returned; in contrast to this "*incomplete*" aerophagy is the silent form in which the swallowed air passes into the stomach, and from there, sometimes after more or less delay, reaches the intestines, where it produces various clinical manifestations. The chemical composition of the gas brought up by the mouth is that of air, for gastric fermentation is incapable of rapidly generating the enormous quantities of gas that are sometimes eructated. Examination by *x* rays clearly demonstrates the passage of air into the oesophagus with gradual distension of the stomach and elevation of the left leaflet of the diaphragm; often when the patient thinks that he is eructating he is really gulping down more air. In the aerophagies the stomach may be large or small, and from distension of the colon an appearance of an hour-glass stomach may result. The cause of aerophagy may be gastric, some irritation reflexly exciting salivation and so swallowing; or extragastric, dental and naso-pharyngitic irritation (which increases the salivary flow), and nasal obstruction. Acute dilatation of the stomach after operation and in childbirth is due to excessive salivation set up by chloroform and deglutition movements made by parturient women during labour. The secondary effects of aerophagy, such as dyspnoea, cardiac pain and palpitation, and colic, are minutely detailed, and the various treatments of the swallowing tic are discussed. Dr. Leven's book is a valuable guide about a familiar condition, which, however, is not generally understood; it should be widely read.

THE CHILD AT SCHOOL AND IN ADOLESCENCE.

"Is Saul also among the prophets?" School doctors and members of school committees are apt to look upon members of central Government boards of health as too often *brakes* upon the wheels of progress. But in a little book entitled *The Child at School*,[3] by Sir LESLIE MACKENZIE, a member of the Scottish Board of Health, there is a fine example of the fact that primary interest need not be destroyed by an official position. The book is one of the series of Modern Health Books, several of which we have had occasion to commend, and is instinct with life and insight into the problems of childhood. The school, as a special organ of the family, has, says the author, a triple function: to instil knowledge, to cultivate intelligence, and to develop character. The first it does by suiting the lesson to the mental age of the child; the second by equipping the child with the methods of acquisition; the third by placing the child in a community of its contemporaries. Success hangs on the capacity of the teacher to select the right knowledge, to assess *individual differences in faculty, and to* create the right atmosphere for the blossoming of personality. The problem would be simpler if every child went to school from a good social environment, having a good inheritance and a good record of personal health. To see that the best is done that can be done is the purpose of the medical administration. All this has to be accomplished in nine short years, with mixed material, and much of it too often damaged in pre-school days. There is one general inference—namely, that until the adverse influences of the pre-school period are adequately counteracted, the schools will continue to be loaded with much preventable disease and defect. One of the most interesting of the chapters is that which discusses the question "*When to go to school?*" The author endorses the conclusion of Mr. Winch that "no advantage appears to exist in early entry so far as subsequent attain-

[3] *The Child at School.* By Sir Leslie Mackenzie, M.D., etc. The Modern Health Books. London: Faber and Gwyer, Ltd. (The Scientific Press). 1926. (Fcap. 8vo, pp. 232. 2s. 6d. net.)

ment of good behaviour and the development of attentiveness are concerned," but he adds that in present conditions "The age of 3 is not too early to begin school, if the school provided is of the right order. Such a school, equipped in the ways now understood in all good nursery schools, kindergartens, and allied schools, offers to the child an environment more adequate for the organization of his impulses towards life in a community than the casual life of the streets or the unsuperintended life of the back-courts." The discussion on the effects of dietary is excellent. Sir Leslie Mackenzie says:

"The food factor tends to supersede every adverse influence. Bad air, over-work, interrupted sleep, diminished sleep, and all other environmental influences have a less destructive effect on the well-fed child. When sleeping time comes nothing will keep him awake. He has more vigour to combat the effects of bad air. He has more energy to neutralize over-work. With his growing energy he becomes more competent to alter his environment and adapt it to himself. He becomes more discontented with every adverse condition. He is more difficult to restrain; but he is readier to learn. A head master of a very poor school has stated that, after three weeks of soup kitchen food, where no scientific attention was given to diet, he always found his children more lively, more mischievous, more fit to react to school."

This little book is essentially one to read and think over; it will be a stimulus to enthusiasm and a holiday to the school worker who has stuck in the rut of routine.

WINIFRED RICHMOND, an American psychologist, in her book on *The Adolescent Girl*[4] traces the treatment of the girl in savage and ancient times, and the strange ceremonies that have initiated her into womanhood. The stories seem impossible to us. Yet it is astonishing what a vast body of ignorance and superstition still adheres to such a natural function as menstruation. There were so many prohibitions of necessary daily work that the reader begins to wonder if the whole system were not really a subtle form of protection for the woman, to secure her a rest where otherwise she might get none! But mothers to-day give their daughters strange directions. The first thing, the writer states, is to induce belief in the naturalness of the period, and then to recognize the great variation among girls in regard to the function. All girls, she thinks, should bathe during their periods, at least as frequently as usual, and a local bath with a change of napkins morning and evening, and once at least during the day if possible, is no more than ordinary cleanliness. Some girls continue their cold tub, even sea-bathing, with no noticeable effects, others are more comfortable after a warm sponge bath. Each girl must find out what is best suited to her. Puberty is not only marked with the beginning of this function; there is evidence of accelerated growth and of increased vitality and power to resist disease. In successive chapters the author develops her picture of varied types, including the abnormal girl and the delinquent girl. Then follows a chapter on the normal girl which is admirably written and full of common sense. Training and education are discussed, and the need for selection according to ability is insisted on. Dr. Winifred Richmond is to be congratulated on her book. We have read few which show better balance, better observation, and a finer judgement of her youthful sisters.

There is a school of research at Harvard University to which subventions from the Commonwealth Fund of the Harvard Graduate School of Education have been made for the investigation of the mental and physical development of school children by means of repeated measurement of the same children over a period of years. Dr. MARY WENTWORTH has collected the results of her own work in the examination of 1,000 children, and published them under the title *Individual Differences in the Intelligence of School Children*.[5] She did not observe any sex differences which she considered important. The medians for girls both in the group and in the individual distributions were about one point higher than for boys, but boys showed a greater range. There were a few more boys than girls among the very superior children, and more boys than girls maintaining high scores in successive tests. A definite relationship was found between mental and anatomical development; retardation in anatomical development accompanied mental retardation, and acceleration in anatomical development accompanied mental superiority in about two-thirds of the cases. This relationship is significant, and indicates the necessity of complete examination before any decision is given. Of twins it was found no two were exactly alike, but some were so similar that a monozygotic origin was assumed; in other cases much doubt was felt in classification. "The marvellous fact of the uniqueness of each human personality is illustrated by the twins in our study, where the resemblance never amounts to exact identity, but is always specialized." In general it was found that superior intelligence did not always bring with it superior emotional or moral attitudes, nor that inferior intelligence necessarily resulted in emotional maladjustment. Any marked deviation from the average was unconsciously sensed, even by young children, and compensatory reactions of all kinds were the result. The book will be of interest to educationists who are just now much absorbed in these psychological tests and in the determination of their ultimate values.

HUTCHISON'S DIETETICS.

Food and the Principles of Dietetics,[6] by Dr. ROBERT HUTCHISON, the sixth edition of which has just appeared, is such a well established and well known textbook that there is little need to point out to our readers its chief merits. This is more especially the case because no extensive alterations have been made in the form of the book since the last edition, which appeared in 1922. The author mentions, however, that the sections dealing with the protein optimum, the vitamins, and the principles of infant feeding have been altered in accordance with the advances in knowledge in these subjects. We were, however, rather surprised to note the statement on page 118 that "Pasteurization, properly carried out, does not interfere with the flavour, digestibility, or vitamin content of the milk." The author doubtless has sound reasons for this statement, but many good authorities are emphatic that the process destroys a large proportion of the antiscorbutic vitamin content of the milk, and since this point is of great practical importance it would have been more satisfactory if the author had given reasons for his conclusion.

Everyone is aware that the preparation of successive editions of a large textbook is a particularly laborious task, and there is a limit to the amount of work that can reasonably be demanded of an author. We cannot help feeling, however, that this book would have been improved by the weeding out of certain phrases that read rather strangely in 1927; for example, in a footnote on page 367 the author says: "Since the above was written an epidemic of arsenical poisoning has occurred from the consumption of 'substitute' beer prepared from impure glucose." This appears to refer to the Manchester epidemic of 1900. Similarly in other places the word "recently" is used of events that occurred rather a long time ago. The retention also of the pre-war prices for foods in certain sections lends an air of unreality to the discussions on the economy of food.

The points we have mentioned are all of minor importance, but there is a danger of phrases such as we have quoted attracting the attention of the reader, and producing a wholly wrong impression of the general quality of this excellent and most useful book.

[6] *Food and the Principles of Dietetics.* By Robert Hutchison, M.D.Edin., F.R.C.P. Sixth edition. London: E. Arnold. 1927. (Demy 8vo, pp. xvii + 610; 33 figures, 3 plates. 21s. net.)

THE LAW RELATING TO DENTISTS.

THE first Dentists Act (1878) prevented unregistered persons from recovering fees for dental work, and stopped the improper use of dental titles, but did not prohibit such persons from practising dentistry. The Dentists Act of 1921 prohibited the practice of dentistry by unregistered persons,

whether for payment or not. The provisions of both Acts, and a further Act passed in 1923, and the regulations of the Dental Board, are set out in full in *The Law and Practice Relating to Dentists and Dentistry*,[7] by Mr. ALBERT CREW, barrister, together with explanatory notes and case references. The Dentists Act of 1921 gives dentists struck off the *Dentists Register* a right of appeal to the High Court. Mr. Crew believes that this right of appeal has been given to the dentist because unless registered he cannot practise at all, whereas the Medical Act of 1858 does not prohibit the practice of medicine and surgery, but provides *inter alia* that none but registered practitioners may recover any charges in any court of law for advice or treatment. The book contains chapters on professional ethics, conduct, and negligence.

NOTES ON BOOKS.

WE have read with appreciation *A Student's Manual of Organic Chemical Analysis*,[8] produced under the joint authorship of J. F. THORPE and M. A. WHITELEY. Many of the analytical operations of organic chemistry will fail of satisfactory accomplishment unless they are performed according to certain empirical rules, which may, indeed, be harmonized with scientific facts. Accordingly there exists for almost every analytical purpose a variety of schemes, each having peculiar merits and defects, arising out of the decisiveness of the reaction employed, the accuracy of the indication, or the convenience of the appliances. Without a knowledge of these the novice must suffer much discouragement from failure to accomplish the practical demonstrations expected from theoretical teaching. This book is, therefore, particularly welcome as the work of experienced teachers, and as one emanating from a laboratory where the methods of organic analysis have been cultivated to a high standard of efficiency. There is, as the authors state in their preface, no science which approaches organic chemistry as a vehicle for facts, and there is, in consequence, no science worse than organic chemistry as a means of mental training if it is wrongly taught. This is strictly true. It means that while the student is learning organic chemistry he must learn also the conditions, determinable by choice of method and manipulation, which favour the peculiar molecular transformation desired. Such methods ultimately become the chief of the organic chemist's sources of inspiration when engaged upon original work. For these reasons, and because the book offers the student a most advantageous opportunity of progress on the lines indicated, we recommend it unreservedly to the student and worker engaged in this branch of chemistry.

The medical administrator faced with an emergency in the form of an outbreak of infectious disease will find Dr. S. H. DAUKES's *Barrier Charts for Health Officers*[9] a compendious and reliable guide. The charts divide the infectious diseases into four groups: (1) the alimentary group, transmitted by the alimentary tract; (2) the inoculation group, carried by insects, etc.; (3) the respiratory group, including pneumonia and measles; and (4) the contact group, comprising syphilis, anthrax, and some other diseases. On each chart the measures for control are set forth under four heads, called barriers, which deal with (1) the sick person, contacts, and carriers, (2) zoological precautions, (3) general hygiene, and (4) specific immunization. The general arrangement of the charts is sound. Bubonic plague, for example, appears under the inoculation group, while pneumonic plague, administratively a different disease, is classed under the respiratory group. Japanese river fever, tularaemia, and other foreign diseases are noted, as well as those common in this country. These charts will not greatly inform the ignorant, but to those who possess the requisite groundwork of knowledge they will serve as a useful stand-by, recalling to the mind appropriate remedies and suggesting the right thing to do.

The recreations of a physiologist are various. Only a short time ago we mentioned that Dr. LEONARD HILL, F.R.S., Director of the Department of Applied Physiology in the National Laboratory for Medical Research, Hampstead, had been holding a one-man show of his pictures and sketches. Now we have received a copy of a set of fairy tales published under the title *The Scarecrow*.[10] It appears that Dr. Hill wrote them for his children, and that he has made his own black-and-white illustrations; some of these, especially those which have anything to do with movement, are excellent in their rather blotchy way. Of a few we must admit that we can make neither head nor tail, though we like the heads and tails of some of the beasts. One story of an elfin which got shut up in the coal measures has a charming picture of a hairy elephant. The book has been issued as a birthday present by a number of his friends and pupils, including everyone now living who has served under him as demonstrator or research assistant. It is offered to him as a token of their affection and respect, and there are, therefore, compensations in reaching the age of 60.

A list of questions on nursing, with model answers, has been compiled by Dr. J. A. FOOTE, and published under the title of *State Board Questions and Answers for Nurses*,[11] the questions being those set at examinations in thirty-one of the United States of America. The subjects include materia medica and therapeutics; anatomy; physiology; hygiene and bacteriology; general, surgical, gynaecological, and obstetrical nursing; feeding and diseases of children; dietetics; chemistry; physics; *nursing ethics; and psychiatric and neurological nursing.*

PREPARATIONS AND APPLIANCES.

A Diathermic Applicator for the Eye.

MR. PHILIP FIGDOR (Physician in charge of the Electro-therapeutic Department, St. John's Hospital, Lewisham) has designed an applicator to simplify the use of the diathermy current in eye diseases. The diathermy current, he writes, has hitherto been applied to the eye by an ordinary glass eye-bath, pierced by a metal terminal. The cup was filled with saline and applied to the eye with the patient in a forward stooping position. With a great deal of manœuvring on the part of the patient and the assistance of the operator, the patient gradually assumed a recumbent position with the eyeball pressed closely to the socket to prevent the escape of the saline solution. A source of discomfort was the pain of pressure of the glass rim. Leakage was both a source of worry and danger, and to refill the applicator the whole procedure of getting the patient to sit up and again to balance the applicator into position had to be repeated. The figure is a cross-section; B is a bar of solid glass connecting a hollow funnel (A) with C, which is a hollow, elliptical eye-bath. Also connecting A and C is a glass arm (E) with a 1/16-inch bore. The cup C has a detachable rubber cap, and is pierced in two places—one an air-hole and the other for the metal electrode terminal.

The applicator is used in the following way. The patient lies on a table with one pillow and the applicator is placed in position on the eye to be treated, with the rubber fitting as closely and evenly as possible into the eye socket, with the electrode terminal already connected up with one pole of the diathermy machine (the other pole is connected with a handle electrode which the patient grasps in one hand). Saline is poured into the funnel A and falls evenly into the cup and covers the patient's eye. When the air-hole is reached the current can be turned on.

Iredell and Meadows Ryley, so far as my search of the literature extends, were the first to apply the diathermy current in eye diseases, and they published their results in a number of cases, which seem to have done remarkably well, in the *Proceedings* of the Royal Society of Medicine, 1919. Since then diathermy in eye diseases seems to have been in abeyance, probably owing to the difficulty of applying it. Although still requiring extreme care and caution on the part of the operator, the new applicator is safer and easier to manipulate. It has been made for me by Watson and Sons (Electro-Medical), Ltd., Sunic House, Kingsway, W.C.2.

Insulin.

With the approval of the Medical Research Council, Burroughs Wellcome and Co. are now prepared to supply insulin 200 units in 5 c.cm. in addition to the regular strength of 100 units in 5 c.cm. This increased concentration will, it is thought, be found convenient by medical men who have patients requiring a high unit dosage. The stronger preparation is carefully labelled and distributed in a carton of distinctive colour.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT.

(*Concluded from page 388.*)

TUBERCULOSIS.

HE Tuberculin Subcommittee has carried out further udies confirming the value of the double intradermal test r the detection of tuberculosis in dairy cattle, and its eat superiority to the subcutaneous test. This test is ow being increasingly used by veterinary surgeons roughout the country. The subcommittee considers that ie ophthalmic test should now be used only as a con rmatory test; it has reason to believe that with certain rands of tuberculin a non-specific ophthalmic reaction ay be obtained after repeated tests, a fact which affords n additional reason for not diagnosing tuberculosis on the sult of the ophthalmic reaction alone. Various investiga ons on the value of sanocrysin in the treatment of tuber ulosis in animals are recorded. Professor S. L. Cummins, orking with rabbits, showed that milder infections could e practically eliminated by the use of this drug, but that osage and virulence of the strain were factors of great mportance; sanocrysin was without avail where the dose as big or the strain relatively virulent. Captain Douglas's results indicate that sanocrysin has no specific ction on the tubercle bacillus, but that it affects the cells o as to give indirect damage to the infecting organisms.

TISSUE GROWTH.

Mrs. B. E. Holmes and Miss Watchorn, working in Sir Frederick Hopkins's laboratory, have studied the produc ion of ammonia and urea by tissues in culture, and have letermined the amount of the chemical changes due to ictual growth. Surviving kidney tissue of the rat embryo roduces neither urea nor ammonia; growing kidney tissue roduces ammonia certainly and probably urea also. Surviving brain tissue of the rat embryo produces no urea, ut converts a large amount of the existing urea into mmonia; this does not occur to the same extent in growing tissue. Rat carcinoma and sarcoma tissue contain abnormally small amounts of glutathione, and they are also deficient in the respiratory pigment cytochrome. These findings are all in agreement with Warburg's contention that cancerous tissue as compared with normal tissue lives under anaerobic conditions rather than aerobic; moreover, cancerous tissues can only reduce very small amounts of glutathione. These observations are being extended, and it is hoped to investigate the glutathione content and the reducing power of aged tissue and of tissues in the pre-cancerous state.

FILTERABLE VIRUSES.

The Council draws renewed attention to the importance of investigations on the filterable viruses. Research into the nature of the infection in measles, encephalitis, polio-myelitis, vaccinia, variola, and herpes is being prosecuted all over the world, and nowhere with greater vigour than at the National Institute for Medical Research at Hampstead; inability to grow the viruses outside the body by any means yet discovered hampers the work in many directions, and prevents any marked progress so far; but, as is observed, information is being gradually accumulated, and any ingenuity that gives a new experimental method of approach at one point may well mean an advance all along the line.

Rous Chicken Sarcoma.

Dr. Gye and Mr. Barnard have continued their study of the filterable virus obtained from the Rous chicken sarcoma. Mr. Barnard's work has been interrupted by transference from Hampstead to the new installation at Mill Hill, where improved facilities have been provided and work is now being pushed steadily forward. A short restatement of Dr. Gye's position is given; the two chief lines of criticism that have been made on his work have been considered. Dr. Gye has so far found no reason to modify his position.

Lethargic Encephalitis.

Dr. Perdrau has made considerable progress with his work on encephalitis lethargica, and into the related problems of the virus of herpes and the immunity reactions to it. Dr. Da Fano has collaborated with him in the micro-pathological investigation, and these workers now find it possible to state definitely that the virus of herpes can cause in rabbits a chronic form of meningo-encephalitis with characteristic microscopical features.

Vaccinia.

Reference has already been made to the difficulty in growing the viruses outside the body, and it is encouraging to note that Captain Douglas records that good progress has been made in this respect with vaccinia virus, using a strain supplied by the courtesy of M. Levaditi from the Pasteur Institute, Paris.

Distemper.

Dr. P. P. Laidlaw and Mr. G. W. Dunkin have carried their attack on distemper in dogs to a further stage. They have already amply confirmed Carré's view that this disease is in fact due to a filterable virus, and that it is not due to bacteria visible by ordinary methods; they have shown also that the disease is transmissible to ferrets and then back again to dogs at will. They have now attempted to produce immunity against the virus by inoculation with a formalin-treated virus. In ferrets, for which the disease is almost invariably fatal, a substantial success has been obtained, and treated animals have, as rule, been able to withstand successfully massive doses of the virus which would otherwise certainly have proved fatal. With dogs the treatment has so far proved much less satisfactory; but there is clear evidence that the disease in them is modified, and experiments are in hand to show whether the desired end cannot be obtained by inducing a mild infection in an animal partially protected by previous treatment with a weakened virus. This work is carried out in collaboration with the Distemper Research Council, which is financially supported by voluntary contributions collected by the *Field* newspaper.

GENERAL BIOCHEMICAL RESEARCHES.

Bacterial Chemistry.

Miss Stephenson and Dr. Quastel are investigating the requirements of strictly anaerobic bacteria. Working with *B. sporogenes*, they find that three constituents of a tryptic digest of casein are necessary for normal growth and reproduction of the organism. One of these is a compound like cystein, thioglycollic acid, or reduced glutathione, and the suggestion is made that the function of this substance is to maintain the medium at a limited reduction potential above which the organism is unable to grow. These studies have led to a re-examination of the current view that the toxic action of oxygen on anaerobes is due to the production of hydrogen peroxide.

The extension of the work of Dr. Gordon and Miss B. Wheatley at Leeds on the effects of amino-acids on bacterial growth has led to results which appear to have practical value. By growing a variety of pathogenic bacteria on samples of peptone broth media to which various amino-acids have been added, Dr. Gordon finds that these acids may be divided into three groups: those which favour growth, those which hinder it, and those which are indifferent. Miss Wheatley, working with the gonococcus in broth reinforced with traces of heated blood, obtained corroborating results, and acting on these observations Dr. Gordon tried growing the gonococcus on medium to which small quantities of taurine had been added; as a result he found a great increase in the size and number of the colonies obtained and in the length of their survival.

Colloids.

Dr. C. G. L. Wolf and Dr. E. K. Rideal, in their studies on the chemical and physical nature of the reactions involved in the Wassermann test, find that the active agent in a specific serum is contained in the euglobulin fraction and is not essentially bound up with the lipoids attached to the

euglobulin. In the precipitation test there is a sensitization of the antigen by a fraction of the proteins of the serum, and the precipitation is caused by the salts of the test fluid acting on the sensitized antigen.

Mr. A. Wormall and his collaborators suggest that "complement" contains a second relatively heat-stable constituent; complement is inactivated by alkaline ammonia salts, and it is shown that the ammonia inactivates a heat-stable constituent present in the end-piece fraction. They also adduce evidence that non-dialysable calcium plays some part in the complement reaction.

Anaesthetics.

The anaesthetic committee has continued the investigations into the impurities in nitrous oxide, and still finds that the most common is an undue percentage of nitrogen. It is hoped to publish a schedule of simple tests for general adoption this year. There has been difficulty in obtaining propylene sufficiently pure; apparently there is some irritating by-product present as yet unidentified. The objectionable odour of ethylene is now believed to be that of ethylene itself and not due to the presence of an impurity as had been suspected. Professor Dixon has been working for the committee on the ignition points of various anaesthetic agents in air and oxygen; he showed that mixtures of ether vapour and oxygen ignite readily at a temperature much lower than the visible red heat of any metals. This fact was at once published, as ignorance of it had been responsible for at least one fatality.

General Physiology, Bacteriology, and Protistology.

Physiology of the Heart.

Dr. G. Anrep has worked on the regulation of the blood circulation and the blood supply to the cardiac muscle under normal and pathological conditions. A new method devised by Dr. H. N. Segall made it possible to separate the thoracic from the cerebral circulation and so to study them independently under controlled conditions. He has been able to show the presence of a rich supply of both vaso-constrictor and vaso-dilator fibres to the heart blood vessels, the tone of the vasomotor nerves being regulated both centrally and reflexly. The coronary circulation was shown to be dependent upon the blood pressure in the brain and upon the composition of the blood circulating in the brain.

Studies in Immunity.

Dr. L. Colebrook, in his work on the pathology and treatment of puerperal infection, has made further experiments bearing on the treatment of generalized infections with haemolytic streptococci. These have thrown new light on the chemotherapy of these infections by arsenical compounds; it has been found possible to extend considerably the period during which the blood can be endowed with an enhanced power to kill streptococci. This has been done by using arsenical compounds of such low toxicity for human white corpuscles and other vital tissues that they can be injected at frequent intervals.

Intestinal Protozoa.

Mr. Dobell and Dr. Laidlaw, using their improved methods of cultivating the intestinal amoebae of man and monkeys, have succeeded in obtaining encystation and excystation of the amoebae outside the body, and have been able to obtain all the stages of the life-history of *Entamoeba histolytica* and several other entozoic amoebae. They have found that the bacteria present in cultures of these amoebae have an important bearing on their growth and development. Prolonged cultivation in starch-containing media may alter the characteristic infective power of *E. histolytica*. The same workers have also investigated the action of emetine and other drugs upon cultures of *E. histolytica* and other entozoic amoebae; as compared with other ipecacuanha alkaloids, emetine and cephaeline are specifically poisonous to *E. histolytica*. Very small quantities of emetine, if continuously maintained in culture of *E. histolytica*, inhibit its development and ultimately lead to its death; on the other hand, comparatively strong concentrations are needed to produce immediate death. Particular attention is drawn to this time factor in the slow poisoning by small amounts of alkaloid, as it suggests a principle of wide chemotherapeutic application.

Mr. Dobell is making a detailed comparative study of the life-histories of different species of amoebae of man and monkeys as they occur in their hosts and in culture; his work in this direction already makes it appear highly probable that the species of endolimax occurring in macacques is identical with that commonly found in man.

Experimental Epidemiology.

Professor W. W. C. Topley and Dr. Greenwood have published further studies in experimental epidemiology; they have attempted to evaluate the relative importance of selection and active immunization as factors in bringing about the increased average resistance shown by mice which have passed through a period of epidemic prevalence. It is concluded that pure selection alone cannot account for the results obtained, and that active immunity plays *some part, and possibly a large one, in* raising the average level of herd-resistance. Further experiments are in progress; two herds are receiving immigrants—one of normal uninfected mice, the other of mice that have been exposed to infection in another herd; the fluctuations in the death rate of the two herds are being recorded.

The phenomena of epidemics amongst wild rodents are being studied by a group of workers at Oxford. Wild rodents have been shown to be subject to periodic fluctuation in numbers; there is a period of increase from minimum numbers up to a maximum, and then an epidemic destroys most of the animals in the population affected, so that they begin again to increase from a minimum. These fluctuations are frequently very regular, and epidemics can be predicted with some certainty; work was begun in 1925 preparatory to an investigation of an epidemic among English mice predicted for the early part of this year.

Concluding Notes.

The work of the Industrial Fatigue Research Board is described in the Board's annual report, which is published separately. There is a short section in the Council's report dealing with the Travelling Fellowships of the Rockefeller Foundation of New York, the arrangements for which have been generously renewed by the Foundation, the awards being again entrusted to the Council. The report ends with a statement of the alterations in the composition of the Council, and a warm and affectionate tribute is paid to the services, both scientific and administrative, rendered by the late Sir William Leishman throughout the whole period of the Council's existence.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee thirty-four cases were considered and £440 voted to twenty-nine applicants. The following is a summary of some of the cases relieved.

Widow, aged 76, of L.R.C.S.Edin. who died in 1893. Her only income is the old age pension. She lives with two sons; the younger is unemployed and the elder finds it hard to keep three persons. Voted £26 in twelve monthly instalments.

Widow, aged 44, of *M.R.C.S. who died in July last from* septicaemia after an operation on a patient. She has two sons; the elder, aged 20, earns £65 a year, and the younger is aged 8. When late husband's estate is settled the estimated income will be about £110 a year. Voted £20.

Widow, aged 55, of *M.B. who died in 1923. She has no* children, and supplements her income of £35 per annum by taking *paying guests.* She lives in her own house, rates on which amount to £25 per annum. She asks for help as she has had no paying guests for the past three months. Voted £18 in twelve monthly instalments.

L.R.C.P. has been unable to obtain work owing to age (70) and recently had a stroke. He is now in a home, and, as his savings are exhausted, is dependent upon charity. Previous help given by the Fund amounted to £68; further £15 voted at this meeting.

Subscriptions may be sent to the Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

British Medical Journal.

SATURDAY, MARCH 5TH, 1927.

OPHTHALMIA NEONATORUM IN MATERNITY WARDS.

ONE of the greatest achievements of preventive medicine has been the reduction in the incidence of ophthalmia neonatorum and the toll of blindness resulting therefrom. But as long as the conditions of birth are what they must be, and as long as virulent organisms obtain access to maternal passages, so long will there be an ever-present danger of the occurrence of this fell disease; and when there are many mothers and infants at close quarters in the same ward that danger is much intensified. In lying-in hospitals a generation ago ophthalmia of the newborn was as often seen as puerperal fever. Now such cases occur in a mere fraction of the patients. This rarity of a once frequent disease is only attained by constant unremitting vigilance; yet in spite of every care there may be cases or even a run of cases. Such an incident has lately occurred in Lancashire.

Five babies were born in the Moorlands Maternity Home at Accrington, and were there at the same time; these babies suffered from the disease; four lost the sight of one eye, and one the sight of both eyes. An action for damages was brought against the board of guardians which maintained the home. The evidence showed that one of the infants developed signs of inflammation of the eyes in a very mild form on the third day after birth, and thereafter the other infants showed the disease. The newspaper reports are indefinite in several important particulars, but from the general description of the symptoms and course of the inflammations it may be inferred that the attacks were those usual to the presence of the micrococcus of Neisser. The evidence showed that every effort had been made by the medical and nursing staff of the home to prevent disease and to check the attacks that appeared. Two separate inquiries were made into the methods of the home—one by a medical officer of the Ministry of Health and another by the M.O.H. for the district. Both officers agreed that there had been no lack of care in the arrangements. The judge, in his summing up, said: "It is a great mistake to suppose there is any duty to provide an ideal state of affairs . . . you can expect no more from persons who undertake this kind of duty than that a reasonable standard of care, skill, competency, and prudence shall be maintained." The jury found a verdict for the defendants.

How best can such standards be attained? What is the most prudent course to follow in the care of these infants? The first principle that must be kept in mind is this: the prevention of ophthalmia neonatorum does not begin with the birth of the infant; it is a matter of ante-natal care. As Gibson of Manchester pointed out so clearly a hundred years ago—when none knew of and some denied the possibility of a *materies morbi*—the disease could be prevented by removing the noxious matter from the maternal passages before childbirth, and if this had not or could not be done then it should be done during delivery, and from the child's eyes immediately after birth. The managers of maternity homes are in a particular difficulty in this matter. They do not know the state of the expectant mothers, and have not the care of them; so that, failing some satisfactory arrangement between the medical officers of these homes and the family doctors of the patients, the home starts under a heavy handicap. The private practitioner has learned the lesson Gibson taught; he knows now that the disease is, in all but the rarest cases, due to the micrococcus of Neisser; ante-natal examinations are becoming the rule, and these, with the knowledge that he has of his patients, give him ample warning of danger. He need not wait for the danger to materialize, for it is now known that even a mild course of treatment—one that is insufficient to eradicate the disease of the passages—will yet be effective in reducing the virulence of the micro-organisms so much that they will be little able to infect the infant's eyes.

The first rule of safety for the managers of maternity homes would be, therefore, that they should only admit expectant mothers who had been examined and were recommended by their home doctors or by the medical officers of an ante-natal clinic. With the mother in the home the next step may be through some system of douching prior to the onset of labour or in its early stages. Many have commended this procedure, others have held it an undesirable interference that may disturb the woman or check labour. But after the birth there are definite steps that must be taken in every case. The first of these is that indicated by Gibson—the removal of the noxious matter from the infant's eyes. In every infant born the face and eyelids are smeared with mucus, and there is often contamination with faecal material. Many employ "first aid" immediately the face of the child is born by wiping each eye as dry as possible with separate pieces of dry cotton-wool. When the mother is settled, then will come the real process of making safe the infant's eyes. The baby is washed, and all agree that the water used for the body should not be used for the face of the infant; that should be washed in fresh clean water, and for obvious reasons. Finally, the eyes themselves may be washed with some antiseptic as a final precaution. What this should be has been a matter of discussion. That some kind of antiseptic should be used in all cases all are agreed, for there is not an infant that may not get some noxious matter into its eyes, if only it be the colon bacillus. The destruction of this with a mild unirrifating lotion may serve to reduce the liability to that slight irritation of eyes so commonly observed and is such a source of anxiety to the doctor, who has to determine whether or not this slight symptom is the onset of a serious inflammation or no more than is seen. There the bacteriologist will be the resource of the cautious clinician. Most, however, are agreed that, whereas in private the doctor has a wide latitude in his practice, in lying-in homes it is safer to assume that the gravest risk has been incurred, and to use some silver solution as the final application to the eyes of all infants born in institutions. In such places Credé's method, when used with knowledge, has been an unqualified success.

But the risks are not ended with the birth and the toilet of the infant. There is an ever-present risk of subsequent contamination of the eyes if by any carelessness napery used for the mother should also be used for the infant. There must be a strict separation of all appliances, and the nurse must be most scrupulously precise in washing and disinfecting her hands after each time of tending to the mother and before the baby is touched. This separateness of attention must extend to all the mothers and infants in the same ward. The ideal would be separate rooms—one

for each mother and child; next to that, cubicles sufficiently divided to prevent cross-communication. Short of some such arrangement a kindly but ignorant mother may undo all the care of the medical officer and the nurses by lending some of her napery to her next-door neighbour, not knowing that her kindliness is fraught with danger. Ante-natal care and supervision is first and foremost as the safeguard against ophthalmia of the newborn. Thereafter scrupulous care and an isolation as clean cut as human nature will allow, as rigorous as the ancient laws of the Levitical code, is the desideratum.

SCIENCE AND THE PREPARED MIND.

THOUGH there are many monuments to Pasteur there is none more appropriate than the fine edition of his collected works now being issued under the direction of his grandson, Dr. Pasteur Vallery-Radot. The fourth volume[1] has recently been published, and is a most fascinating record of investigations into the silkworm disease by one who was probably the most famous master of research which the world has yet seen.

The subject is graphically portrayed, because we have presented to us Pasteur's original papers and reports, together with the various documents and notes which passed between him and J. B. Dumas and the Minister of Agriculture, and his replies to numerous opponents, in particular the cultivators, who resented his being delegated to undertake the work, on the ground that he was a "mere chemist," and neither a silkworm cultivator nor a zoologist. The whole story, which reads like a romance, is well summarized by the editor in his introduction. The mulberry, as the food for silkworms, whose cocoons at one time brought in the enormous revenue of 100 million francs in a single year, had been appropriately designated "the Tree of Gold." Owing to disease among the worms, however, the silk industry had fallen away almost to nothing, and the cultivation of the mulberry had become a thing of naught because all efforts to rear healthy silkworms appeared hopeless.

In 1865 Pasteur had completed his researches on fermentation, had saved the wine and vinegar industry, as told in Volume III. of this series, and incidentally dealt a mortal blow to the advocates of spontaneous generation. It was his intention and ardent desire to apply his energies to the study of contagious diseases and their causation, relying on the methods he had elaborated for the isolation of "germs," the employment of sterile culture media, and his surmise that these diseases were due fundamentally to fermentative processes. This intention, however, he reluctantly postponed, and, yielding to the solicitation of J. B. Dumas, who had witnessed his saving of one important industry, and prompted by his sense of patriotism, he put away for the time his ambition, in order to come to the rescue of France and try to save another important industry, which at this time was bankrupt if not moribund—the silk industry. At first he felt great diffidence in undertaking the investigation, telling Dumas that the subject was one of which he was completely ignorant, and that he had "never even touched a silkworm"; he was persuaded to take the matter in hand, and, by systematic study and the application of sound scientific principles, he succeeded in solving a problem which had baffled his predecessors, who had worked more or less haphazard.

This investigation occupied Pasteur for five years, and just when he had, as he believed, solved this obscure problem he found that the silkworms were subject to two diseases. That which was best known, to which he first gave attention, was *pébrine* (a name derived from the patois *pébré*, owing to the presence of disease spots like pepper-sprinklings in the worm), or "corpuscle disease" (from the little brownish-black spots indicative of the affection), or, yet again, *gattine* (derived from the Italian *gattino*, because the infected worms were said to raise their heads and thrust forward their feet after the manner of a cat in the act of scratching). He showed that *pébrine* was due to certain "corpuscles," and that the disease was transmitted through the larval stages from the egg to the imago, and that the healthy moth might acquire it by feeding on infected leaves. He crowned this part of his work by demonstrating how the disease could be eradicated by isolating the females so as to obtain unmixed broods of eggs and by retaining for breeding purposes only those which were healthy. Having arrived at this stage, and confident that his labours in this respect were finished, he met with a sore disappointment, which, however, he was able to turn to further advantage by renewed research, and which in the end redounded to his further credit. A box of healthy eggs turned black and died on reaching the cocoon stage, leading him to proclaim despondently, "Il y a deux maladies." To be brief, he demonstrated that this other infection, *flacherie*, which caused the deaths of many larvae, was due to a vibrio reproducing by means of "spores" and developing in the alimentary tract of the insect, and itself contagious.

The whole fascinating story affords an example, and an outstanding one, of science and the prepared mind; for Pasteur, though at first "roaming about in realms unrealized," intuitively hit upon the chief cause in quite the early stages of his investigation, and spent the following years in testing and re-testing his surmises, leaving nothing to chance and no point unproved, until he could present the whole subject vividly before the world. To prove the soundness of his reasoning, when the commission at Lyons requested him to send some guaranteed healthy seed (eggs), he forwarded, not only the healthy, which he predicted would thrive, but also three other lots for control—namely, "seed" infected by *pébrine*, others infected by *flacherie*, and a mixed lot of both; these last three he predicted would fail, and all turned out exactly in accordance with his prognostications.

Full credit must be given to Pasteur's able and enthusiastic assistants and collaborators — Gernez, Duclaux, Raulin, and Maillot—and to the unremitting encouragement and support he obtained from Dumas and from Béhic, the Minister of Agriculture, during the years when he had to meet and overcome considerable opposition, not only from the obstinate and ignorant, but also, unfortunately, from certain scientists envious of his success.

> "Such is the fate of place and the rough brake
> That virtue must go through."

The re-establishment of the industry, however, proved the soundness of his work, and the outstanding merit of this and his previously published researches on fermentation gained him the Copley Medal of the Royal Society in 1875, a fitting recognition of unselfish labour.

[1] *Œuvres de Pasteur* Réunies par Pasteur Vallery-Radot. Tome IV. Études sur la maladie des vers à soie. Paris: Masson et Cie. 1925. (Imp. 8vo, pp. viii + 761; illustrated. £1 3s. 4d.) The first volume dealt with his work on crystallography, the second with *fermentations* and so-called spontaneous generation, and the third with the *diseases* of wine and vinegar.

LISTER CENTENARY IN LONDON.

We are now able to give some additional details with regard to the provisional arrangements for the Lister centenary celebrations in London next month. On the morning of Tuesday, April 5th, delegates will be received at 11.30 in the Great Hall of the British Medical Association, Tavistock Square, by the Prime Minister. Three delegates from abroad will give short discourses dealing with the effect of Lister's work on surgical and pathological science and practice in their countries. Delegates from other countries will present addresses, but will not be expected to read them. At 4 p.m. there will be a conversazione at the Royal College of Surgeons of England, and in the evening the Merchant Taylors Company will give a dinner in its hall, 30, Threadneedle Street. On the morning of the previous day (Monday, April 4th) the King will receive the delegates at Buckingham Palace, and in the evening (8.30) the Royal Society of Medicine will hold a reception at its house, 1, Wimpole Street, when Sir StClair Thomson will give an address. The memorial service in Westminster Abbey on Wednesday, April 6th, will begin at 11.15 a.m., and an address will be given by the Bishop of Birmingham (Dr. E. W. Barnes, F.R.S.). Delegates who may wish to do so will have an opportunity of placing wreaths at the memorial tablet to Lord Lister in Westminster Abbey. The hour at which the three discourses will be delivered at the house of the Royal Society of Medicine on that afternoon is 3 o'clock: the first will be by Sir Charles Sherrington, O.M., F.R.S., on Lister as a physiologist; the second by Professor W. Bulloch, F.R.S., on Lister as a pathologist; and the third by Sir Berkeley Moynihan, Bt., P.R.C.S., on Lister as a surgeon. The Royal Society will give a conversazione at its rooms in Burlington House at 9 o'clock that evening. Ladies accompanying delegates will be admitted to all the ceremonies, with the exception of that at Buckingham Palace and of the dinner at Merchant Taylors' Hall, to which personal invitations will be issued. An information bureau will be opened in the rooms of the Royal Society, Burlington House, on Saturday, April 2nd, and Sunday, April 3rd, from 10 a.m. to 5 p.m., and tickets for the various receptions and ceremonies will there be issued to the official delegates. The bureau will also be open from 9 a.m. on Monday, April 4th, but it is hoped that the majority of delegates will not defer application until that day. The Lister exhibition in the Wellcome Historical Medical Museum (54A, Wigmore Street) will be opened for inspection by the delegates from 9.30 a.m. to 6 p.m. on and after Monday, April 4th. All communications should be addressed to the Secretaries of the Royal Society, Burlington House, Piccadilly, London, W.1.

THE HISTORY OF INSULIN AND ITS MANUFACTURE

DR. H. H. DALE, director of the Department of Biochemistry and Pharmacology of the Medical Research Council, presided at the Royal Society of Arts on February 23rd, when a paper was read on the manufacture of insulin. Dr. Dale said that the manufacture of insulin was a very important achievement of British industry. When the discovery of insulin was first made known he was a member of a small deputation sent out to Canada by the Medical Research Council to report on the subject. He and his colleagues felt that there could be no question as to the genuineness and importance of the discovery, but had a certain doubt as to the steps to be taken to provide insulin in this country. Some were inclined to the view that the manufacture here would be hopelessly handicapped, chiefly because one large and justly honoured American firm had been closely concerned in the counsels of the institution in which insulin was worked out, and so was already a year ahead, and also because the slaughtering industry in America was on a vast scale and magnificently organized, whereas in this country it was on a small scale and comparatively unorganized. Thus there was a great deal to be said for the view that this matter was better left to the Americans. But the British manufacturing industry was not inclined to agree, and the result had been an achievement which was justifiably a matter of national pride. Within eighteen months of the return of the deputation manufacture was started by several firms in this country, and now, not only had British firms caught up with American in respect of quality and output, but had an excess production enabling them to export to countries which had not been able to get to work so quickly. Moreover, the price of insulin had been reduced to a level which would at first have seemed incredible; at the beginning insulin had been a rich man's remedy, but to-day that position had completely changed, and even if the poor man had to pay for it himself it represented not much more than he would afford for tobacco. Dr. Dale added that he was glad to have the personal friendship of the devoted and ingenious young workers who had brought this thing to a final solution in one of the great Dominions. He would not diminish by a breath the credit that was rightly due to them, but at the same time they had forerunners who were also deserving of thanks, especially Professor Minkowski, who had just retired, and whose experiments as far back as 1889 laid the foundation of the knowledge which was bound in due course, once the right method was discovered, to lead to the production of such a substance. He wished also to say this, that this work had resulted from experiments on animals, chiefly and inevitably on dogs. At that moment there was a bill before Parliament which, if carried, would make the continuance of this work impossible in this country—in this country alone among the civilized nations of the world. He had the greatest respect for our legislators, but he was bound to say that on such a matter he would have preferred that the decision could have rested on the vote of those who knew by personal experience the difference between the life they lived in the pre-insulin era and the life they lived now. Mr. Francis H. Carr, president of the Society of Chemical Industry, then read his paper, in the course of which he exhibited what he called a "flow sheet" of insulin manufacture, from the collection of pancreas at the slaughterhouse, through more than twenty processes of extraction and purification, to the actual production of insulin. In brief, the process consisted of dissecting the pancreas glands, grinding or mincing, rendering the material acid to *p*H 2.5 or alkaline to *p*H 7.0, in order to set free the insulin from the tissue on which it was adsorbed, extracting it with alcohol of such a strength that but little of the enzyme was dissolved and as much as possible of the insulin, clarifying the extract, concentrating at a low temperature, precipitating the proteins, and, finally, formation of picrate and regeneration as a hydrochloride. Purification was thus effected by combining the use of precipitants, such as picric acid and ammonium sulphate, with iso-electric point precipitation. Mr. Carr said that when first the manufacture was started the yields obtained were very low, being but 50 units to the kilogram of pancreas. There was also at first a great loss of alcohol. As knowledge extended and the plant was perfected, it had been possible to increase the yield twentyfold and to reduce the loss of alcohol to a very low figure. The selling price of insulin was thereby reduced by successive stages within the first year of its manufacture from 25s. to 2s. 8d. for a bottle of ten doses. At the same time, it had been possible gradually to improve the purity of the insulin as issued for use. Mr. Carr also referred to the fact we mentioned last week, that quite recently three German workers—Frank, Nothmann,

and Wagner—had discovered a derivative of guanidine which produced effects similar to those of insulin, though much less intense. Guanidine itself had been shown to be too toxic for use in the treatment of diabetes, as had another guanidine derivative, agmatine, which was prepared from herring sperm, but this new guanidine derivative was said to exercise on diabetic patients the same effects as insulin, though more slowly, and it had the advantage that it could be administered by the mouth. Unfortunately, it was not devoid of toxic effects, and an overdose caused loss of appetite, nausea, and vomiting. Nevertheless, it was the opinion of the German workers that it might usefully be employed to supplement insulin treatment, or might be used by itself in mild cases. Perhaps its greatest interest was that it might prove a step in the direction which, through the study of other derivatives of this nature, would lead to a true substitute for insulin. The elucidation of the chemical nature of insulin itself was a step to be most profoundly desired; it might involve the destruction of £1,000 worth of insulin, but the priceless contribution to human happiness which the discovery of insulin represented made even that expense no more than a grain of sand on the seashore. Once the chemical nature of insulin was understood, it was not too much to expect that the history of adrenaline and thyroxine would be repeated, and the manufacture of artificial insulin, indistinguishable from the natural product, be possible. Mr. Carr's paper was all the more appropriate in view of the fact that one of the most impressive exhibits in the very greatly enlarged chemical section of the British Industries Fair at Shepherd's Bush was an insulin-manufacturing plant working as a continuous process.

A CENTURY OF PHYSIOLOGY.

UNIVERSITY COLLEGE is including in its centenary celebrations a series of addresses. The first was delivered by Professor E. H. Starling, F.R.S., on February 28th, and was entitled "A century of physiology." Professor Starling noted that the celebrations coincided with the centenary of the birth of Lister, with the jubilee of the Physiological Society, and almost with the three hundredth anniversary of Harvey's book on the circulation, which marked the birth of modern physiology. The resuscitation of observation by the anatomists was followed by the resuscitation of experiment by Harvey, whose method was experiment and induction. The investigation of the functions of other organs than the heart had to wait a long time, so that a hundred years ago physiology was still backward, though progress had been made by Malpighi, Stephen Hales, and others. When the exact sciences of chemistry and physics were called in to aid, physiology began to advance. Lavoisier's researches on the conservation of matter, and Helmholtz's on the conservation of energy, helped in the advancement, but physiology was not freed from its fetters until 1871. From 1850 to 1870 Claude Bernard investigated the vasomotor system and the sugar functions of the liver. From 1863 to 1875 Marey examined the mechanics of the circulation. At the end of fifty years physiology had become an exact science. There had been an awakening of the human spirit, due largely to the fact that men of wide sympathies were employed to impart old knowledge and new learning. Such a man was Sharpey. His works were anatomical in nature, but he was a great teacher; and his pupils were destined to initiate modern physiology. Professor Starling sketched briefly the careers of Michael Foster and his pupils Gaskell, Langley, Sherrington, Balfour, and Vines; of Martin, who went to Baltimore; of Burdon-Sanderson; and of Ringer. He showed that Sharpey was thus the originator of physiology in London, Oxford, Cambridge, Liverpool, and the United States. Co-operation of physiologists with one another, however separate their places of residence, was shown in the foundation of the Physiological Society, since the science could not be kept within the four walls of any building. The lecturer then mentioned the work of Lewis on the electro-cardiograph; Ringer's investigations of the action of salt solutions on the heart; and his own work with Bayliss on internal secretions. He concluded by saying that the past history of the college in physiology was full of hope; that the golden age was supposed to be an epoch of great achievement; but that the work of physiology in medicine had only just begun. At the conclusion of the address a vote of thanks to Professor Starling was adopted, on the motion of the chairman, Sir John Rose Bradford, President of the Royal College of Physicians, London, and consulting physician to University College Hospital, who next May will himself give another of the centenary series of addresses, when his subject will be "University College, London, and medical education."

FOOT-AND-MOUTH DISEASE.

THE committee appointed in 1924 to investigate foot-and-mouth disease has just published its second progress report,[1] which reviews the work carried out during the past year. The committee points out that research into this disease is peculiarly tedious and necessarily slow, and consequently the work is still far from completed. Guinea-pigs are being extensively used for experimental work, and by this means lines of research can be more quickly investigated than if the large farm animals were employed. Attempts to cultivate the virus have consistently failed, and the view is expressed that the Frosch-Dahmen discoveries were susceptible of another interpretation. Until the virus can be cultivated animals must be used as reservoirs from which the material may be drawn, and it has been found that by successive passages through guinea-pigs a virus of high potency can be obtained, and this may be kept for some time without any great loss in virulence; in some instances it was maintained for over a year before becoming impotent. Virus obtained from the blood is not so strong as that recovered from the vesicles. It was found that although rapid drying quickly destroyed the virus, it survived slow drying provided that it was maintained in a dry condition; but it is not suggested that in ordinary circumstances virus dried on inanimate objects would survive for long as a source of infection. Virus dried on hay, woven fabrics, and so on, remained active for some considerable time; the time varied with the nature of the substance—on woollen fabric for between two and three weeks, on hay eight to fifteen weeks, on bran up to twenty weeks, and so on. A calf contracted the disease from hay a month after this had been infected, demonstrating that fodder might be a natural source of infection. The virus was also found to remain alive for considerable periods in blood and bone marrow, and was in this way recovered from imported pig carcasses. Light, and 0.1 per cent. formalin, as well as various other chemical disinfectants, were found to destroy the virus in fluid from the vesicles. The committee has confirmed the plurality of types (to which we have previously referred), and it has shown that in the vast majority of cases the O type was present in Britain; only on one occasion (from an outbreak in Sussex) was the A type recovered. These types are fixed, and do not change their characters after repeated subinoculations. Investigations on small mammals showed that rodents other than guinea-pigs could be infected by direct inoculation, but the disease is hardly ever passed from one to another by natural means. Neither dogs nor cats are easily infected, but young animals are more susceptible than adults and cats than dogs. Birds appear to be refractory. Artificial

[1] Ministry of Agriculture. 1927. H.M. Stationery Office. 3s. net.

immunity has also been studied. Guinea-pigs appear to be immune for about three months after having passed through an attack, but after that the immunity gradually disappears, the local immunity ceasing before the general immunity. Inoculation with the serum of a hyperimmune animal stops generalization of the disease from intradermal inoculation, and may prevent all symptoms from intramuscular injections. A small dose of active virus may also produce a partial active immunity, while a virus (vaccine) treated with formalin regularly produces a partial immunity in guinea-pigs, and sometimes complete immunity results. There is as yet no evidence that a virus so treated will in small quantities protect cattle, but a sufficient dose will protect a majority of the animals. Attempts have also been made to use a combined serum and vaccine in cattle, and although only a few animals have been treated the results are promising. The report contains a mass of detailed evidence, of which what is here written is only a partial summary. Although no definite decision is immediately possible the results are distinctly promising, and augur well for, we hope, a not too distant future when our method of eradicating foot-and-mouth disease with a pole-axe will be replaced by the more scientific and more accurate one of the hypodermic syringe.

TOTAL CYSTECTOMY.

IN another part of the JOURNAL (p. 425) will be found a report of the paper read before the Urological Section of the Royal Society of Medicine by Mr. Henry Wade on the treatment of malignant disease of the bladder. In it Mr. Wade expresses the view that palliative measures, including the use of radium and of deep x-ray therapy, have failed, and that the only hope of effectually dealing with the condition lies in surgical extirpation. He advocates the more frequent employment of the operation of total cystectomy, which, he thinks, should be regarded, not only as a means of dealing with operable cases in which there is a hope of entirely removing the growth, but also as palliative treatment for the relief of the pain and extreme discomfort that is the fate of every patient dying of malignant disease of the bladder. He envisages the time when, with improvement in technique, especially with regard to the preliminary transplantation of the ureters, total cystectomy will become a routine operation, and urges those who deal with these difficult cases to spare no effort in doing the preliminary work that will be necessary before this ideal is reached. Mr. Wade's views will not be readily accepted by a great many surgeons. Total cystectomy is a mutilating operation, and it is only the failure of all other methods to mitigate the sufferings of a patient dying of malignant disease of the bladder that can render it justifiable. When, however, we remember how great are those sufferings we cannot fail to welcome any effort, however heroic it may be, to combat them. At some future date, when the vast amount of research that is being conducted on the subject of malignant disease has borne fruit, such mutilating operations as total cystectomy will probably be looked upon as relics of a bygone age. Medical men will refer to the heroic efforts of the old surgeons to deal with malignant disease by means of the knife in the same terms that we at the present moment employ when we discuss the efforts of pre-Listerian surgeons to deal with hospital gangrene. But alas! those days are not yet come, and at the present time the only weapon in the fight against most forms of malignant disease is the knife. In the case of some other organs, such as the breast, there has been a reaction against the extensive operations practised ten years ago, but it would appear from Mr. Wade's remarks that in dealing with carcinoma of the bladder our best hope lies in methods that are still more sweeping. If this be so, and if a desperate remedy must be adopted for a desperate disease, we can only hope that those who are called upon to undertake such a mutilation as total cystectomy will succeed in so improving the technique that the operation will be freed from some of the difficulties that at present attend it, and the comfort and the safety of the patient be thereby increased.

PROGNOSIS IN INSANITY.

THERE is a widespread popular belief that diseases of the mind are incurable, and that "once a madman, always a madman," is a correct representation of general experience. Every now and then effect is given to this view by juries in cases of alleged wrongful certification, when the jurymen, seeing the patient now sane, refuse to believe that he was once out of his mind, and may punish the certifying medical man for taking those very measures which restored the patient to health. In the new number of the *Journal of Neurology and Psychopathology*, which, as our readers know, is now published by the British Medical Association,[1] this pessimistic view of psychotherapy is combated in an editorial article. Some striking statistics are quoted from an article by Dr. Earl D. Bond, whence it appears that out of a total of over a thousand consecutive mental cases admitted to the Pennsylvania Hospital, over 26 per cent. remained well for at least five years, and were not known to have suffered relapse afterwards. As most of these patients were suffering from the more severe types of mental disease, these figures are sufficiently striking, especially when looked at in conjunction with the fact that only one-third of the remaining cases did not improve. To those unfamiliar with the treatment of mental disease it may come as a surprise to learn that a certain number of patients seem in the long run actually to be benefited by an attack of acute mental derangement, which, as the writer of the editorial article in our contemporary says, appears "to have a cathartic effect—it clears the air, as it were, and affords a release of pent-up emotional tension." In a similar way, according to some observers, an acute illness such as pneumonia or carbuncle is sometimes followed by the disappearance of symptoms of mental derangement, and it is possible that these two events may stand in the relation of cause and effect. There seems no reason to suppose that an attack of malaria has a specific effect on general paralysis of the insane, and it is therefore thought probable that its curative properties lie in the pyrexia and the profound disturbance, the shaking up, of the whole nervous and circulatory systems. It is not possible to compare Dr. Bond's figures with those relating to physical disease, for there is little information as to what happens to patients who come consecutively to any surgical, medical, or special hospital, or to the consulting rooms of general practitioners or specialists. There are plenty of statistics about many diseases, but none about the general run of patients. The editorial writer suggests that the surgeon, physician, or general practitioner would be satisfied with the return to full function in 25 per cent. of his consecutive cases, judgement being made five to ten years after the beginning of treatment. As even when patients are seen late by the psychiatrist consecutive cases may be expected to show a full return to health in 25 per cent., and amelioration in 15 per cent. more, it is argued that the general practitioner first, and the psychiatrist later, may feel justified in taking as hopeful an attitude as for surgical cases. Although specific remedies for the cure of psychoses are not known, spontaneous cures occur which have no parallel in purely physical diseases of a chronic type. Since some such patients recover there can have been no irreparable structural change. The editorial article thus ends on

[1] To be obtained from the British Medical Association, Tavistock Square, London, W.C.1. Annual subscription 30s.; single numbers 8s. 6d. post free.

a note of confidence and hope for the future, which we venture to think is well justified by the considerations set forth, and in this connexion we would commend to notice the admirable speech on present-day lunacy administration by Earl Russell in the House of Lords, reported at page 446. The same issue of the *Journal of Neurology and Psychopathology* contains a number of original articles of particular interest to specialists, as well as a series of abstracts occupying thirty pages, and many reviews and notes on books.

INFLUENZA.

IN the week ended February 26th there was a decrease in the number of deaths from influenza in London, but taking London and the 105 great towns of England and Wales together there was an increase, the number being 1,023, as compared with 990 in the previous week, and 759 in the week before that. In London proper the total deaths fell from 128 to 81, and in outer London from 112 to 67. The highest number in any town in the country last week was at Manchester, where the deaths rose from 36 to 88. The reports received by the Scottish Board of Health suggest that there were more persons suffering from influenza last week than in any other week this year. There was a large increase in the number of cases in Dundee, following on the rise in absences from school reported in the previous week. The medical officer of health estimates that there were between 4,000 and 5,000 new cases, but says that the type is mild, and is not regarded by medical practitioners as true influenza. A much heavier incidence is also reported from Motherwell and Wishaw and from Dunfermline (though Kirkcaldy had fewer cases), while less marked increases occurred in Hamilton and Ayr and the counties of Lanark and Fife. In the north of Scotland influenza has been prevalent for some weeks in most districts. There have been many absences from school, and in a few cases schools have been closed. The symptoms seem to have been much the same as elsewhere in Scotland, a sore throat often being the first sign, and there have been comparatively few cases of complications, but an attack often leaves behind it a persistent cough. Aberdeen burgh is one of the few places in the north able to report a lower incidence. In Edinburgh the slight epidemic seems definitely on the decline. There is little change from the normal in Glasgow. There are no cases in Clydebank, but elsewhere in Scotland no considerable fall in the number of cases has been observed.

RABIES.

THIS country shares with Australia and New Zealand, and a few other countries, including, according to Mr. Frederick Hobday, F.R.C.V.S., Norway and Sweden, the distinction of being free from rabies, a disease which is present in every other country of the world. Great Britain has been kept free by a rigidly enforced quarantine on all canine animals entering the country. A letter in the *Times* last week pleaded for a reduction of the present six months' period of quarantine, and suggested that this was fixed as the result of panic legislation. Those who signed that letter entirely miss the point of our antirabies legislation. They state that a dog which has been infected with the disease "normally" develops symptoms within three months of having been bitten. In this they are quite correct; but they overlook the point that longer periods are known, and it is against the abnormal cases that we must take preventive measures. The Minister of Agriculture, in a reasoned reply to this letter, showed that not only was the period of six months fixed as the result of experience, but that within the last few years it has actually been necessary to prevent the entry of several cases where the infective period was well over the three months suggested. Mr. Hobday has recorded in the *Times* the case of a dog in quarantine which was about to be released after the usual six months' detention, but was retained at the request of the owner, who happened to be abroad, and died after showing all the symptoms of rabies (confirmed by *post-mortem* examination) a fortnight later. It is imperative that rabies should be kept out of the country, and until biological means are available which can be thoroughly depended upon to do this we must needs rely on adequate and stringently applied quarantine. Recently a single-injection vaccine has been extensively used abroad in countries where the disease has become a menace—in the United States, for example—and in these countries it has proved its value. It has been used entirely as a preventive, and has been almost exclusively employed to protect dogs against future bites. Its value, if any, as a curative vaccine for animals which have been previously bitten by a rabid dog has yet to be proved; indeed, such evidence as is available suggests that it is not effective in this respect, and accordingly it cannot be used to replace an effective quarantine in such countries as Great Britain, which are free from the disease, although it is proving invaluable in those places where the disease is endemic. It is a truism that when rabies is eliminated in the dog it will also be eliminated in man; but until this has been done throughout the world, or until there has been discovered a vaccine which can be relied upon to prevent the disease from developing in animals which have already been bitten, we cannot afford to sacrifice the security of the country to the interests of a very small minority.

R.S.P.C.A.

IN a leading article published last week on the experimental method in the healing art (p. 390), and also in a note on page 394, it was mentioned that the Royal Society for the Prevention of Cruelty to Animals was using its position and influence to obtain signatures to a petition to Parliament to forbid all experiments on dogs. It is now announced that the society has reconsidered its position, and that the council has informed the branches of the society that its support of the bill has been withdrawn. The petition of the National Canine Defence League is, however, being persevered with. We quoted last week (p. 390) the second paragraph of the league's petition, which insinuated that it was on account of the docility of the dog that it had "of late years been specially selected by vivisectors for extensive and peculiarly revolting and painful experimentation, and also for demonstrations of a prolonged and agonizing nature before classes of students." As we said last week, the substance of this statement is false. The Science Committee of the British Medical Association is meeting this week (March 4th), but too late for us to announce any decision it may come to.

SIR ARTHUR KEITH began a course of six Hunterian lectures on the peoples of the East, past and present, at the Royal College of Surgeons of England on Wednesday last. The third lecture, on Monday next, will contain an account of the earliest Sumerians so far discovered; it will be based on a study of human remains found at and near Ur of the Chaldees. The fourth lecture, on March 9th, will deal with the racial characters of Sumerians and Babylonians, and their relation to other peoples. The lecture on March 11th will be on the people of Egypt, past and present; and the last lecture, which will be given on March 14th, will discuss the distribution of racial types in southern and western Asia in past times. The hour of the lecture is 5 o'clock on each day.

New Zealand.

[FROM OUR CORRESPONDENT.]

HOSPITAL FINANCE.

THE hospital boards in New Zealand have a dual function—that is, not only the administration of public hospitals, but also of charitable aid by way of indoor and outdoor relief. For the past year the expenditure for these purposes has been: Hospital maintenance, £925,000; charitable relief, £371,000; administration, £49,000; interest on loans, £52,000; district nursing, £18,000; capital expenditure, £578,000; total, £1,993,000. The total income of the boards for the year was £1,473,000, of which sum £580,000 was a direct grant from the Government, and £526,000 was obtained from rates levied by local bodies. To the Government contribution there must be added a further sum of £107,000 expended on thirteen hospitals administered directly by the Government, but towards the maintenance of which it received £68,000 in payment by patients. The Minister of Health states that New Zealand has more hospital accommodation per head of population than any other country in the world, and that no other country has a lower general death rate, tuberculosis death rate, or infantile mortality rate. The main reason for the great amount of hospital accommodation in this Dominion is the scattered population. There is a tendency for the smaller hospitals to undertake too much because they are in comparatively isolated positions, but with improved means of transport they must become increasingly subordinate to the hospitals in the larger centres of population. The hospital rate in Dunedin is 4½d. in the £ on the property of the ratepayers living in the city and surrounding district, and this rate at the present time is barely sufficient.

WESTERN SAMOA.

Western Samoa is a mandated territory under the control of the New Zealand Government. The report on the public health of the islands for the year ending March, 1926, shows steady progress. The Samoans are not a dying race, and gained in the year, by natural increase, 1,176, the total population being about 38,000. Infantile mortality was unusually high owing to the prevalence of whooping-cough. As 16 per cent. of the native population are under the age of 4 years, child welfare work has been of prime importance. The medical service in Western Samoa has done much towards the eradication of hookworm and yaws. The latter disease is almost eradicated in its infectious stage. The Samoans, recognizing that at least three injections of novarsenobillon are necessary for a reasonable chance of cure, have passed a law in their native parliament to compel persons suffering from yaws to undergo the necessary treatment. The medical officers of the Health Department in Samoa, as the result of their experience, are convinced that one attack of yaws produces an immunity against subsequent attacks of either yaws or syphilis. They are producing a juvenile non-immune population, but they hold that the non-immune population that is gradually growing up will not be liable to spread syphilis through the islands for at least ten to fifteen years. With a highly efficient medical service in this mandated territory there is reason to believe that syphilis can be as easily controlled as yaws.

England and Wales.

DISTRICT NURSING IN LONDON.

SIR WILLIAM COLLINS, presiding over the annual meeting of the Central Council for District Nursing in London on February 24th, said that during the twelve years of its existence the council had distributed £44,797 to its federated associations. In the annual report it was stated that the main work of the council during the year 1926 had been the further consolidation of district nursing in London and extension of the service on the outer borders of the county and in Middlesex. A new association had been established on provident lines at Eltham Hill; two Ranyard nurses had also taken up work there, and additional nurses would shortly be required for the new estate at Roehampton. Good progress had been made by the new association formed at Twickenham at the end of 1925, and there had been considerable increase in the work undertaken by that for Osterley, Hounslow, and Heston. A nursing association at Ealing had been federated with the council, and at Mill Hill an association affiliated to the Queen's Institute had been re-formed. The Willesden association began to operate in September, and in Hornsey efforts were being made to co-ordinate the associations already at work, and to extend district nursing to the whole borough. Although it had not yet been possible to make permanent arrangements for Tottenham, the co-operation of the North London and Hackney District Nursing Associations with the Sisters of St. Vincent de Paul had borne fruit in very valuable work. It is hoped that a district nursing association may be established in Tottenham when the present temporary arrangements come to an end next May. In view of the prolonged period of midwifery training now required, and the increased fees, the midwifery bursaries have each been raised to £30; three were awarded last year. The council reported also that its invested funds were practically exhausted, and that unless fresh sources of income could be found shortly the annual allocation of grants would have to be reduced. A distribution of £1,000 from invested funds was made during 1926. The trustees of the London Parochial Charities entrusted the council with £2,800 for distribution, £300 for administrative work, and £100 for midwifery bursaries, and £766 was received from the Ministry of Health in respect of the midwifery and nursing carried on by certain associations. The representatives of the British Medical Association on the Central Council in 1926 were Dr. T. W. H. Garstang, Dr. William Paterson, and Mr. E. B. Turner.

HEALTH PROPAGANDA BY THE LONDON COUNTY COUNCIL.

At the meeting of the London County Council this week the Public Health Committee submitted a report on the publication of information on health questions. The Council's powers in regard to health propaganda were previously limited to the subject of venereal diseases (work which was undertaken on the Council's behalf by a voluntary association), but under the London County Council (General Powers) Act, 1926, extended powers have been obtained to enable the Council to undertake or assist such work on the preventive side of public health as appeared desirable. The Public Health Committee is of opinion, however, that in view of the activities of voluntary bodies and the interest now taken in the public press in all matters concerning the health of the individual and the community, it is unlikely that there will be any scarcity of useful information available to the public on health questions, and that the Council should confine itself for the present to the circulation from time to time among medical officers of health of the metropolitan boroughs and medical practitioners of such medical information in the possession of the Council as it would be difficult for them to obtain in a comprehensive form without considerable study and research. The matter would be restricted to information which could not readily be obtained from any other source, and discrimination would in each case be exercised in its distribution. It might also be desirable to issue to the press on special occasions statements as to any epidemic diseases. The Council does not propose for the present to make any arrangements for the delivery of lectures or the display of pictures.

COMPLETION OF THE SCHOOL MEDICAL SERVICE.

The Board of Education has issued a circular (1388) with reference to the standardization of expenditure by local authorities, which is now being gradually accomplished. The concluding paragraph deals with the School Medical Service, and is as follows.

6. *Special Services.*—Under this head the Board feel that the first aim of national policy should be the completion of the School Medical Service. It will be understood that the Board do not underrate the value of special schools, but while no rule can be laid down which is universally applicable to all areas and to all types of physical defect, the completion of the School Medical

Service would appear to be of primary importance, and the Board suggest that authorities should concentrate on this definite aim. With regard to provision for mentally defective children, authorities will be aware that this very difficult problem is now being explored by a special committee, and, save in exceptional circumstances, it would not seem prudent to incur heavy expenditure at the present moment on new schools for such children or on enlargements of existing schools. The adoption of such a policy may make it necessary for authorities to reconsider their programmes under this head, and in some cases to substitute proposals in regard to the School Medical Service for proposals involving additional special school accommodation.

DORSET COUNTY HOSPITAL: AN OPHTHALMIC DEPARTMENT.

A new ophthalmic department was presented to the Dorset County Hospital on February 17th by the Society of Dorset Men in London, in memory of its first honorary secretary, the late Mr. William Watkins. The new department includes a dark-room for refraction, with special lighting and equipment for the examination of patients of all ages. Lord Ellenborough, chairman of the hospital committee, explained that the original suggestion for establishing an ophthalmic department came from the late senior honorary surgeon to the hospital, Dr. W. B. Cosens, but was not then carried out, for financial reasons. Sir William Lister, consulting ophthalmic surgeon to the London Hospital, gave an address on the place of the ophthalmological department in a general hospital, emphasizing the importance of team work. In many general diseases diagnosis depended upon an ophthalmological examination by an expert, while in general surgery an ophthalmic surgeon could give much assistance in certain cerebral conditions with regard to diagnosis, prognosis, and treatment.

POST-GRADUATE LECTURES IN THE PROVINCES.

It has been brought to the notice of the Fellowship of Medicine that certain provincial schools and medical societies are desirous of supplementing their ordinary courses of instruction by inviting teachers connected with the Fellowship to give special lectures from time to time at their school or society. We are asked to say that the Fellowship is prepared to accede to any such request, and would be glad to hear from those provincial schools which are desirous of procuring such lecturers in order that definite arrangements may be made. Its address is 1, Wimpole Street, London, W.1.

Scotland.

MEN'S HOSTEL AT EDINBURGH UNIVERSITY.

At a meeting of Edinburgh University Court it was announced that Mr. Thomas Cowan, retired shipowner, Leith, had offered a sum of £15,000 to enable the University to carry out a scheme for providing a residential house for men students. Mr. Cowan previously gave £10,000 to the University in appreciation of the work done by students during the general strike. The Court gratefully accepted the offer and decided to use the amount to provide a residential hall, to be called Cowan Hall, by adapting a row of houses on the south side of George Square, with necessary additions in the gardens behind. The house should accommodate about 125 students. Although small residential halls have already been instituted for certain definite groups of students, this is the first important step towards removing what has often been regarded as a reproach to the Scottish university system—the absence of provision for communal life among students.

VITAL STATISTICS.

The Registrar-General for Scotland has issued a short preliminary statement on the vital statistics of 1926, which will in due course be published in full in his seventy-second annual report. The births during the year numbered 102,450, equivalent to a birth rate of 20.9 per thousand, which is the lowest since 1918. The marriages were 31,241, a rate of 6.4 per thousand, which is the lowest since 1917. The deaths registered during the year were 63,775, corresponding to a death rate of 13 per thousand, the lowest on record with one exception. The proportion of illegitimate births, 6.9 per cent., is less than the mean of the last ten years. Deaths of children under 1 year numbered 8,515, giving an infantile mortality rate of 83 per thousand births, the lowest recorded with one exception. The death rate from pulmonary tuberculosis was 69 per 100,000, from all forms 99. Both these rates are the lowest yet recorded. Deaths from malignant tumours numbered 6,641, 34 below the previous year, but 690 above the mean of the last ten years. Among the larger burghs high birth rates were recorded in Coatbridge, Hamilton, and Greenock, 26.1, 25.8, and 23.9 respectively, and high death rates in Glasgow, Dundee, and Paisley, 15.1, 14.8, and 14.2 respectively. There were high death rates from epidemic diseases in Paisley, Glasgow, and Hamilton, and from pulmonary tuberculosis in Greenock, Falkirk, and Glasgow. In 1926, compared with the previous year, there were, over all, fewer deaths from enteric fever and pneumonia, but more from measles, influenza, encephalitis lethargica, and cerebro-spinal meningitis.

GIFFORD LECTURES IN GLASGOW.

In his last two lectures in the Gifford course in the University of Glasgow Dr. J. S. Haldane discussed psychology as an independent science. It must, he said, be regarded as a branch of knowledge dealing with the full experience of personality and the interest and values expressed in it. Since interest and values concerned questions of time as well as of space, psychology must be regarded as independent of biology. The view to which his course of lectures had led was that knowledge represented in psychological sciences was differentiated clearly from other kinds of scientific knowledge and was the most fundamental variety of scientific knowledge. He could not accept the view that physical science was the most fundamental variety of knowledge. In the concluding lecture Dr. Haldane said that the survey of the sciences had shown the difficulties and contradictions to which mere scientific interpretations of our experience led. These difficulties and contradictions concerned all that was of most moment and value. We might be materialists for whom, theoretically speaking, there was nothing but mechanical chaos in the universe, which involved experience as well as material happenings, so that such things as spiritual values could not exist. At the other extreme we might, he said, be religious mystics to whom the chaos of the visible universe was theoretically of no account. When we examined the body of knowledge presented to us by each science we found that it only corresponded partially or imperfectly with actual experience. Science brought us to a point at which we required more than science, and he hoped to pursue this subject further in his lectures next year.

GLASGOW ROYAL INFIRMARY.

At the annual meeting of contributors to Glasgow Royal Infirmary, the Lord Provost, who was in the chair, said that during the past twelve months a greater amount of work had been done in the infirmary than at any previous period in its existence, both as regarded indoor and outdoor patients. The average daily number of patients in the wards had been well over 700, although the reconstructed infirmary had been planned for a normal number of 664. He also referred to the celebration in April of the centenary of the birth of Lord Lister, who had been closely associated with the infirmary from 1861 to 1869. Authority was given to spend £65,000 on extensions, including the completion of the gatehouse block, which will contain casualty wards, a large hall for visitors, and a lecture theatre, which will be commemorative of Lister and will stand virtually on the site of the ward, recently demolished, in which Lister did his work during his Glasgow period. Mr. James Macfarlane, LL.D., chairman of the managers, said that before beginning to build the auxiliary hospital at Canniesburn, where a site of 31½ acres had been presented to the infirmary, it was decided to have from £50,000 to £60,000 in hand, and of this fully half had been already received by voluntary subscription. The out-patient department and the ophthalmic institution were both at present inadequate to cope with the demands which were made upon them, and plans were under consideration for housing both departments in one building, to be erected on a site recently acquired by the infirmary in Collins Street and Cathedral Street.

MENTAL STRAIN AMONG SCHOOL CHILDREN.

The Scottish Education Department has issued a circular about the leaving certificate examination, in which it is stated that the undoubted prevalence of overpressure among candidates presented for the examination has for some time been giving serious concern to the department. The results of excessive mental fatigue may become immediately evident by conspicuous failure to pass, or, on the other hand, the damage done to health may not reveal itself until permanent impairment of vitality is found in later years. Only a relatively small number of pupils have a real gift for the linguistic and mathematical subjects which form the backbone of school and university study. To reduce the time for physical training in the later stages of study is a mistaken policy, which defeats its own end. In adolescence the demands on the vital resources are peculiarly heavy. Mental strain actually hinders the satisfactory growth of body and mind; it may have a bad influence on conduct, and certainly reduces the effective power of resistance to diseases such as tuberculosis. Everything possible should be done to lighten the burden of those children whose home circumstances are difficult or who have to undertake a long journey to and from school. The department considers that the general situation can be met most satisfactorily by close co-operation between school medical officers and teachers, and the vigilance of the school medical officer should be redoubled during the last two years of the secondary school course. Teachers should always be on the watch for signs of overstrain and should direct the medical officer's special attention to pupils whose work shows unexpected deterioration. The need for such attention is said to be particularly great in the case of girls, who do not so readily as boys strike a happy mean between idleness and overwork. Among the symptoms of overstrain mentioned are a tendency to unusual sleepiness during the day, over-anxiety with regard to lessons, and a distaste for games and physical exercises.

Correspondence.

SUBSCRIPTIONS TO THE ASSOCIATION.

SIR,—The application for payment of the 1927 subscription to the British Medical Association met with a very good response in the first two or three days of this year. More than 10,000 cheques, representing about one-third of the members, were received within the first week, and for this response the Finance Department desires to express its sincere thanks, but there are still many members of the Association who have not yet forwarded their subscriptions for the current year, and the additional cost of preparing and posting reminders to those whose subscriptions are outstanding involves each year a large sum which could be better employed in the Association's interest.

An earnest appeal is therefore made to those who have not already remitted to send their subscription for 1927 immediately, adding thereto such sums for the charities or the other funds mentioned on the application form as their instincts prompt and their means will allow.—I am, etc.,

L. FERRIS-SCOTT,
Financial Secretary and Business Manager.

British Medical Association House,
Tavistock Square, W.C.1, Feb. 25th.

THE MENTAL DEFICIENCY BILL OF 1926.

SIR,—While recording my admiration of Dr. Tredgold's faithful advocacy of this unfortunate bill, may I be permitted to comment on two of its suggestions.

The Definitions.

The weakest clause in the Act of 1913 time has shown to be that containing the definitions; it is easy now for some to maintain that this clause should never have been admitted; yet, if the framers of 1913 altogether could not have foreseen the consequences of their Act, what subtler justification have the advocates of 1926 in desiring to tinker with and not to delete this clause? One is curious, also, to ask why this fervid endeavour to define a pathological condition, admittedly difficult of definition, in a legal document? Is it really necessary for the inexpert layman dealing with these cases to consider, in every instance, whether or not the condition present existed "from birth or from an early age," as required by the Act, or is "innate or induced after birth by disease, injury, or other cause," as proposed by this bill?

Let us consider this principle from another point of view. Does the law require, for example, that a lay magistrate shall be convinced that an alleged case, say, of small-pox, is small-pox before the public health authority may take steps to isolate it? Is even the term "infectious diseases" defined in any of the Acts that deal so successfully with these conditions? Had it been defined, would these Acts have worked as easily and as efficiently as they do? Should we not have seen extraordinary exhibitions of forensic skill, paid for at hundreds of pounds per day, triumphantly demonstrating that that particular case of small-pox was not small-pox, but simply German measles? Errors in diagnosis, of course, occur in the world of the exanthemata, but how many isolation hospitals have been arraigned for the unlawful detention of the innocent?

A time there was when many maintained that to drive unfortunate men and women and little children from their happy homes to the dreary isolation hospitals, there to contract a multitude of evils, to prosecute and fine them if they refused to go, was an unjustifiable interference with the liberty of the subject, when honest men contemplated with genuine horror "this growing power of the doctors." That time, happily, has passed, and to-day the public health authority enjoys the confidence it deserves, because it has expected nothing less and rightly resented even the remotest reflection on its integrity or its intelligence, because in all things pertaining to the public health the law has learned to mind its own business, and does so contentedly and without undue affectation. Has not the time come when psychiatrists should demand a corresponding courtesy?

There is, of course, a distressing difference. Doctors long have been trained in the detection of infectious disease, but the systematic study of amentia is still unknown in our medical schools—and, naturally, the public is suspicious. Yet the remedy, I fear, is not in the making of many definitions.

The addition of the words "or not under proper care or control."

Writing elsewhere,[1] as one of sixteen signatories, Dr. Tredgold points out that

"under Section 2 (*b*) (1) a mental defective can only receive the protection of the Act if he be neglected, abandoned, or without visible means of support or cruelly treated. Experience has revealed the fact that these restrictions tell very hardly on, for example, a mother of a mentally defective boy or girl (under 7, or over 16, and not notified by the education authority), for whom she is anxious to secure the treatment and training that can only be obtained in a properly equipped and staffed institution. Unless she is able to pay the whole cost of maintenance, the case can only be dealt with on the plea of 'neglect.' This is a hard word, and has occasioned much grief and sorrow. In one sense he (or she) is neglected—he is not receiving the care, training, and control for which his condition calls—but his mother is giving him all the attention possible for a working woman to give and naturally resents having to plead 'neglect.' The addition of the words 'not under proper care and control' would meet the case."

But—and this is important—that devoted mother may not obtain the benefit she desires for her child unless and until she consents that he (or she) is first subjected to, what many mothers would consider, the indignity of certification. In other words, and to put it crudely: no certification, no benefit.

But why? Is not the modern trend in dealing with mental conditions to avoid certification, or, in any case, to delay it to a date as far off as possible? Did not the recent Royal Commission recommend that certification should be resorted to only as a last measure, and in the most extreme cases? That was for "lunatics"; but if for lunatics, why not for the feeble-minded? Certification certainly is a protection for the neglected, the abandoned, and the cruelly treated; it is an excellent means of compelling the unwilling; but that the child of the devoted and

[1] *Times*, January 22nd, 1927.

intelligent parent, only too anxious for its welfare, shall be similarly dealt with, that that child shall not be trained unless it is first certified, is this desirable? What is wrong with the principle of the *aided* "voluntary boarder"? If this principle is considered to be of definite value in dealing with the insane, why should it not prove to be of equal, or greater, merit in training the feeble-minded?—I am, etc.,

Epsom, Feb. 23rd. H. FREIZE STEPHENS.

WIRELESS CALLS FOR MEDICAL HELP AT SEA.

SIR,—In the BRITISH MEDICAL JOURNAL of February 12th (p. 307) Dr. F. F. Bond calls attention to the fact that there exists no method of codification of calls for medical help at sea. A practical way out of the difficulty lies in the supplying of every wireless-carrying vessel and lighthouse with printed forms worded as below.

Case Report Form.

1. Report No. (A, B, C, etc.).
2. Patient No. (1, 2, 3, etc.).
3. Date and time of sending (or receiving) message.
4. Rating (or position, occupation, etc.) of patient.
5. Age of patient.
6. Sex.
7. Type.
8. Habits (if normal signal "Nor.").
9. Time of onset of illness, and date.
10. Onset sudden or gradual? (signal "S" or "G").
11. Complaining of—(if pain signal "P," if unconscious state most obvious symptoms).
12. Previous health (if healthy signal "H," if previously ill recently state what illness, if unknown signal "U").
13. If previously in tropics (signal "Y" or "N" for "Yes" or "No").
14. Pulse rate per minute.
15. Respiration rate per minute.
16. Temperature.
17. Shivering?
18. Vomiting (if contents unusual, state).
19. Bowels (if open signal "O"; if not open in past eighteen hours signal "C"; if diarrhoea signal "D").
20. Urine passed (if unusual character, state).
21. Cough (if unusual character, state).
22. Any unusual swelling (if so, position).
23. Any skin erupt on?
24. Exact site of pain (e.g., right lower abdomen, left upper abdomen, back of chest, etc.).
25. Any known cause for condition (if unknown signal "C. U.").
26. Treatment already given.
27. Further information or comment.
28. Sender.
29. Location.

Reply from medical officer.....

Time and date of receiving (or sending) reply.....

Messages relating to sickness or accident on board could then be sent out, and received, with reference to one of these forms—the number of each question on the form preceding, in the message, the answer to that question. Thus a case of acute appendicitis in a seaman might be reported in this way:

"1, A. 2, 1. 3, 11.2 p.m., 4th. 4, AB. 5, 35. 6, M. 7, Robust. 8, Nor. 9, 4 p.m., 4th. 10, S. 11, P. abdomen. 12, H. 13, Y. 14, 100. 15, 20. 16, 100 point 6. 17, N. 18, Y. 19, O. 20, Y. 21, N. 22, N. 23, N. 24, R. L. abd., severe. 25, N. 26, Poultices, Epsom. 27, Appears v. ill, advice re treatment required; if thought necessary, please send surgeon. 28, Captain, SS ——. 29, (Position)."

The printed form would thus act as a key to the message and as a permanent record. A system such as this would, I think, provide a ship surgeon with sufficiently exact and sufficiently full information about any distant case upon which his advice might be sought. The foreign language difficulty could be overcome by the use of esperanto.—I am, etc.,

VERNON NEWTON, M.R.C.S.,
Corps Surgeon (St. John Ambulance Brigade),
Bridgend and District.

February 13th.

THROMBO-ANGIITIS OBLITERANS.

SIR,—We have had at the London Jewish Hospital during the last two years five cases (all Jews) of thrombo-angiitis obliterans and senile gangrene, and in none have we had to resort to high or even low amputation. In all of them we performed Leriche's operation (periarterial sympathectomy), and followed it up with various therapeutic measures, aiming at the encouragement of the capillary circulation, which is supposed to be in a healthy state.

Two of the patients have done very well and returned to active life; one man had to be readmitted for removal of gangrenous toes, and so far he has not responded to any treatment, and it is to be feared more radical measures will have to be taken; the fourth had improved considerably after the operation, but had a recurrence of pain, and committed suicide; the fifth could not be traced.

It appears to me that Sir William Wheeler's condemnation of Leriche's operation (February 5th, p. 226) is rather too harsh. Most surgeons will agree that the operation has the striking and immediate effect of relieving pain, though doubt may be expressed by some as to how far it inhibits the forward march of the gangrene. If Leriche's operation is performed in the early stages, before gangrene is definitely established, the prognosis is much better; it is of doubtful benefit in late cases.

Once amputation is decided on, I think low amputation should be resorted to. A Russian Jew, 55 years of age, had both his legs amputated about twenty-five years ago—one by the late Professor Israel of Berlin above the knee, and the other by Sir Berkeley Moynihan below the knee. The patient never had any more trouble since the operation, and leads a very effective business life. Intermittently he has pain and cyanosis in his fingers, but he manages to keep these attacks down to an inconsiderable minimum by frequently resorting to hot-air baths, radiant heat, etc.

May I add that one can hardly ascribe the cause of the disease to cigarette smoking? While it is true that in the past Jewish women abstained from tobacco, they hardly do so now. The advancement of civilization has penetrated the East End, and Jewish women help now considerably to the paying of the huge dividends by the tobacco companies. Besides, two patients of our series were mild smokers.—I am, etc.,

London, W.1, Feb. 26th. M. SOURASKY.

MIGRAINE.

SIR,—With reference to Dr. C. P. Symonds's remarks on migraine, at the Royal Society of Medicine on February 26th (p. 376), the following case seems to be worthy of record. A married woman, in the middle thirties, suffered from typical attacks of migraine on which various drugs had had little or no effect. A diet, as far as possible purin-free, was arranged for her, and the attacks became less frequent and less severe. She was in the habit of accompanying her husband when, as frequently, he made a journey from Manchester to Bristol, as she had friends in the latter place, and it was noted that she usually had an attack after the return journey. On cross-examination she confessed that she was tempted by and had taken soup when lunching on the train; soup was prohibited, with the result that subsequent journeys were taken without any return of migraine as a consequence.—I am, etc.,

London, Feb. 27th. O. H. WOODCOCK, M.D.

PUERPERAL SEPSIS.

SIR,—I have before me the report for 1925 of the East End Lying-in Home mentioned by Dr. Fairbairn in the BRITISH MEDICAL JOURNAL of January 8th (p. 50). It is amazing reading. Indoor, 1,087 mothers were delivered, with 2 cases of sepsis; outdoor, 1,092, with no sepsis. Since 1884, 18,647 in-patients have been delivered—sepsis, 3 cases; outdoor, 24,683—no sepsis.

Glasgow Maternity Hospital figures for 1925 are: Indoor, 2,897—sepsis 49; outdoor, 3,840—sepsis 43. At this rate, since 1884 there have been 2,009 cases of sepsis in the maternity against 3 in London, and 1,720 in the outdoor, against none in this London home. The East End Lying-in Home, I understand, is run by general practitioners and nurses.

Professor Munro Kerr, I believe, never did general practitioner work, but has adorned the Glasgow Maternity Hospital all his medical life. He uses his great position, not to deplore this sepsis, for which he is jointly responsible, but to condemn that of the general practitioner,

which is no worse than his own. What does he think of the London home?

Might I ask Dr. Fairbairn if he ever worked as a general practitioner? If so, how long? and what was his sepsis rate? It is worse than useless being a critic if one is not also an example.—I am, etc.,

Dennistoun, Feb. 17th. JAMES COOK, M.B., Ch.B.

Obituary.

EDWARD SWAN SIMPSON, *M.C.*, M.D.,

Medical Superintendent, East Riding Mental Hospital.

WE regret to record the death of Dr. E. S. Simpson, medical superintendent of the East Riding Mental Hospital, which occurred at Beverley, after a short illness, on February 2nd.

He was born in Edinburgh in 1882, and was educated at George Watson's School. He received his medical education in the University of Edinburgh; he graduated M.B., Ch.B. in 1905, and proceeded M.D. in 1910. He held also the certificate in tropical medicine of that university. In 1905 he was appointed assistant medical officer to the East Riding Mental Hospital, and in 1919 succeeded Dr. Archdale as superintendent. He served the hospital for twenty-two years—exactly half his life.

He was a member of the British Medical Association, and an active member of the council of the Medico-Psychological Association. He was an able psychologist, a sound general physician, a man of considerable mental culture, and a good administrator; his hospital was very efficiently conducted.

During the war he served overseas with the 1st/3rd Northumbrian Field Ambulance, and was then posted, at his own request, to the 4th Green Howards as regimental medical officer. He was a gallant and efficient officer, and was awarded the Military Cross for his service during the great retreat in the spring of 1918.

His was a very full life. He was at once a scholar and a sportsman; for many years he was secretary to the Beverley and East Riding Golf Club, and was captain in 1926; he was a keen fisherman, a noted raconteur, a hospitable host, and a welcome guest wherever he went. He was an ardent Freemason, and three weeks before his death was installed Worshipful Master of the Constitution Lodge of Beverley. Simpson was beloved by all who came in contact with him; his geniality endeared him to his friends, and his unfailing kindness and consideration for his staff and his patients will not be soon forgotten. His loss is deplored, and great sympathy is felt for his widow at his early death.

A service was held in the hospital chapel on February 5th which was largely attended by his friends and colleagues, and his remains were interred at Edinburgh on February 6th.

After a long and trying illness Dr. JOHN ROBERT MITCHELL died on February 9th at Chester-le-Street, where he was born in 1875. He received his medical education at the University of Durham College of Medicine, Newcastle-on-Tyne, and graduated M.B.Durh. in 1900. After preliminary experience with older practitioners, he settled, in 1902, in the East End of Newcastle-on-Tyne, where he built up a large general practice, and held also the position of Poor Law medical officer and public vaccinator for the parish of Walker. Painstaking and conscientious in the performance of his duties, he was highly respected and loved by all who knew him—by his colleagues for his probity and the soundness of his views, and by his patients, particularly the poorer ones, for his unfailing kindness and the unremitting care which he devoted to all, without distinction. Dr. Mitchell was a man of very strong opinions, which he never hesitated to voice when necessary. In spite of the numerous calls of a large practice in an industrial area he kept himself well abreast of current medical thought and teaching, and for some years was one of the assistant physicians to the Newcastle-on-Tyne Hospital for Diseases of the Skin. During the war Dr. Mitchell joined the staff of the Northumberland War Hospital as an assistant surgeon; early in 1916 he was accepted for general service, with a commission in the R.A.M.C. The unsettled conditions of army life undermined his constitution, and in April, 1918, he was invalided out. He retired to Chester-le-Street, and never recovered sufficiently to resume practice, although he did occasional duty at the Newcastle-on-Tyne Skin Hospital. His patience, cheerfulness, and fortitude throughout his illness were a constant source of admiration to his friends and acquaintances. Dr. Mitchell was a member of the British Medical Association, the Newcastle-on-Tyne Clinical Society, and the Heaton Medical Society. He was buried in Chester-le-Street Cemetery on February 12th, and the funeral was attended by a large number of his friends from Northumberland, Durham, and Yorkshire.

Dr. GEORGE EDWIN PEARCEY, who died at Sunderland on January 6th, was born in 1859. He was the son of James Pearcey of Southwick, and was educated at the University of Durham, graduating M.B., B.S. in 1894. After a term as house-surgeon at the Newcastle Infirmary he went into general practice in Sunderland. He was for many years physician to the Sunderland Provident Dispensary, and also in an honorary capacity to St. Joseph's Home for aged poor. Dr. Pearcey was a keen member of the British Medical Association, and had served on the executive committee of the Sunderland Division. He was also an original and much esteemed member of the Sunderland West End Medical Society. During the war he was commandant of the St. Gabriel's Voluntary Hospital. He was warden of St. Peter's Church, Bishopwearmouth, a representative on the Ruridecanal Conference, and a member of the National Assembly of the Church of England as a representative of the Durham Diocese. Dr. Pearcey's loss will be much felt by his brother practitioners, to whom he was a most loyal colleague. He married Anne, daughter of Joseph Williams, shipbuilder, of Monkwearmouth, and is survived by three daughters.

The Services.

MEDICAL DIRECTOR-GENERAL, R.N.

SURGEON REAR-ADMIRAL ARTHUR GASKELL, C.B., O.B.E., F.R.C.S.Eng., D.P.H., has been appointed to succeed Surgeon Vice-Admiral Sir Joseph Chambers, K.C.B., C.M.G., M.D., F.R.C.P.I., K.H.P., as Director-General of the Medical Department of the Navy, to date July 1st, 1927.

Admiral Gaskell was born in 1871, and after studying medicine at University College Hospital, London, joined the Royal Navy in 1893. He was promoted staff surgeon in 1902, fleet surgeon in 1906, surgeon commander in 1920, and three years later surgeon rear-admiral on being appointed to the charge of R.N. Hospital, Plymouth. He has held many appointments afloat and ashore, and has published various papers connected with the Royal Naval Medical Service. For his services during the war he was created C.B. in 1916, and O.B.E. in 1919.

ROYAL ARMY MEDICAL CORPS.

Temporary Commissions for Home Service.

THE War Office announces that there are a number of vacancies in the Royal Army Medical Corps for temporary officers for service at home stations.

Candidates for these commissions must be registered medical practitioners, under 55 years of age, and they will be required to give an undertaking to serve for at least six months. After that period appointments will be terminable by a month's notice on either side. But if they so desire, accepted candidates who fulfil the necessary conditions as to age, etc., will be considered for *permanent commissions*. Pay *for those who have not previously* served in the Royal Army Medical Corps will be at the rate of £600 per annum; but the initial rate for those who have served for not less than twelve months as officers of the corps will be £650 per annum. In each case there will be an outfit allowance up to £40. Applications should be sent to the Under Secretary of State, the War Office, Whitehall, S.W.1, from whom full particulars may be obtained.

VOLUNTEER DECORATION

THE Volunteer Officers' Decoration has been awarded to Surgeon Commander H. J. W. Brennand, R.N.V.R.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons on Monday discussed the Government's delay in ratifying the Washington Convention on hours of labour. On Tuesday the Poor Law Emergency Provisions (Scotland) Bill was read a third time, and the House discussed the appeal from the "necessitous" areas for aid in relief of rates. The other business of the week was not of direct medical interest. In the House of Lords the Committee stage of the Diseases of Animals Bill was set down for Thursday.

On Monday Dr. Haden Guest, the member for Southwark, North, informed Mr. Ramsay MacDonald that he did not propose to remain a member of the Parliamentary Labour Party. Next day that party called upon Dr. Haden Guest to vacate his seat in Parliament without delay. Dr. Haden Guest has been an active member of the Parliamentary Medical Committee, and was one of its officers while the Labour Government was in power.

The Parliamentary Medical Committee met at the House of Commons on February 23rd, but decided to postpone the election of officers for 1927. Dr. Watts has secured the right to draw attention to vaccination and small-pox when the House goes into Committee on the Civil Service Estimates about the end of May; the Medical Committee is considering whether all members of Parliament should previously be invited to an open meeting to hear a statement of the medical view. The Medical Committee also considered the Dogs Bill, which is down for second reading on April 29th, and it is probable that there will be a deputation of medical members of Parliament to the Government on the subject. The Committee was of opinion that when the Party Whips are nominating members to serve on committees for bills which raise medical questions they should include some medical members, and representations will be made to this effect.

Lunacy Administration.

In the House of Lords, on February 24th, Earl Russell called attention to the report of the Royal Commission on Lunacy and Mental Disorder, and asked whether the Government proposed to introduce legislation. It was, he said, important that the idea of lunatics being violent and dangerous people for whom the primary treatment was detention should be removed from the minds of the public, and that from the minds of the patients should be removed the impression that they were being wrongfully detained and wrongfully treated. In the quarter of a century since he was engaged in inspecting asylums the old apparatus of locks, bars, and prison-like surroundings had very largely gone. He had in mind a private institution where 30 per cent. of the patients were allowed to go freely into the town on parole. He called the attention of the House to the misunderstood class of paranoiacs—persons subject to a fixed delusion, but who otherwise might be reasonable, clean, and intelligent. Women not infrequently had the delusion that some distinguished public man was their lover or husband and was being wrongfully kept from them; when that did not lead to action, it was not for the law to interfere, but when molestation followed the woman had to be restrained. Earl Russell detailed the case of a man who, having the delusion that he had been wrongfully convicted for stealing meat from a stores, broke windows there whenever released from the asylum, though when detained he showed no signs of insanity or delusion. In such a case visitors to the asylum might report that a sane person was detained. The Royal Commission on Lunacy had made special inquiries into all allegations of wrongful detention, but had not traced in the asylums of this country a single case where a man was wrongfully detained. Nor did it come across a case in which it could say that a man had been wrongly certified, though there were cases of a process which ought to be very serious and responsible being a little too much of a routine. A curious thing about certification and the early stages of mental disease was that the most obstreperous and obviously insane of the persons to be certified were generally those soonest cured and discharged. The well behaved lunatic with one obsession was the man for whom hope was generally absent; his fixed delusion was associated with an idea of persecution which grew till he developed homicidal tendencies towards the person he believed to be the persecutor. The Royal Commission was much struck by the enormous number of mental cases which it was possible to discharge, and had considered whether some provisional treatment could not be provided without the stigma of certification, which was apt to cling for life, because the public thought "once a madman, always a madman." If there were to be a provisional stage, should it be on the doctor's certificate alone, or on the doctor's certificate backed by an order of the justices? As the violent cases gave the most hope for cure, restraint would be necessary during this provisional treatment. An allied question was that of classification in the early stages. He believed there was some truth in the allegation that in the receiving ward of a workhouse for the mentally defective every class of mental disorder was herded together. Doctors were not so sure as laymen that such association had the worst possible effect, it being minimized by the fact that many mental cases lived in a world of their own. Still such association was extremely undesirable, as the sights and sounds must distress people suffering from less advanced stages of mental disease. Closer classification would mean more medical officers and attendants, smaller wards, and in many cases new buildings, involving expenditure of public money for which at present it was difficult to ask. But such expenditure would give a return in the smaller number of lunatics to be maintained. In most of the rate-aided asylums an increase was desirable in the number of medical officers and in that of attendants. Wards were too large and individual attention too difficult. Watchfulness, care, and individual observation of those for whom there was any hope of preparing for discharge was the only way of getting maximum discharges from asylums. The chief pride of the superintendent of an asylum was the number of inmates he managed to restore to their friends. The advances made in the last twenty-five years had not been due to the Legislature nor to the county councils, but primarily to the initiative of the medical men themselves. No drug or specific treatment would cure mental disease. The only course was to do what doctors now recognized that they did with physical diseases—put the patient into the best condition to fight the disease himself. He hoped that in any legislation the Ministry of Health would consider whether, in provisional treatment, it was necessary to invoke the justices. This was done because of the old and utterly fallacious idea that the doctor, as an enemy of the human race, was trying to put an innocent man into prison. The justice could only satisfy himself by conversation with the doctor or in a few cases by seeing the patient. Such safeguards were not needed in ninety-nine cases out of a hundred. The expectation Parliament held in 1890 that licensed houses for the reception of lunatics would die out had not been fulfilled. Parliament should decide whether it was fit that licensed houses should exist. If they should, then there should be free trade in them, one effect of which would be a better geographical distribution. If the licensed houses were to be abolished, what accommodation should be provided for persons who could afford to make their choice of institution? Standardized accommodation would be resented by that class. The Board of Control was understaffed. Even if the Government could do nothing else with regard to the report of the Royal Commission, the number of the Board should be increased. Earl Russell, in concluding, suggested that the postponement of the Poor Law Reform Bill gave an opportunity to present a bill this session on the reform of the Lunacy Laws, if only for first reading and public study.

Lord Sandhurst, one of the Lord Chancellor's visitors, said there was no controversy over the necessity of early treatment. The law should be reformed so that voluntary boarders could be received into rate-aided institutions. The Mental After-Care Association did invaluable work, but the care of patients leaving asylums should not be left to, and could not be adequately performed by, any charitable institution. A difficulty in carrying out the present law arose in the natural hesitation of the medical profession in certifying patients. Recent cases had alarmed them, and they felt they were not adequately protected against subsequent litigation. There were clear cases where the interest of the patient and the public made supervision desirable, but where it was difficult to find medical men who would certify. He doubted whether the safeguard proposed by the Royal Commission would suffice to inspire confidence in the medical profession, and suggested that damages recoverable in an action for wrongful certification should be limited to one month, at the end of which a special report had to be made to the Board of Control, limiting the period during which detention could be attributed to the certificate. The whole matter was ripe for legislation, and it would be an advantage if reform of the Poor Law and that of the Lunacy Law were considered together.

Viscount Gage, replying for the Government, said that legislation would give rise to controversy on grounds quite apart from the medical and scientific aspects, and the Harnett case had shown the necessity of avoiding obscurities in the new proposals. The Royal Commission had not made unanimous proposals about licensed houses. The report had only been presented last July, and as close consideration of scientific, legal, financial, and administrative aspects was required, the Government must claim more time for investigation. Until the Government's proposals for the reform of the Poor Law were crystallized discussion of the administrative side of the Lunacy Commission's report would be almost useless. The Government regarded the report as most valuable.

Lord Haldane said it would be much better if the Government proceeded with the drafting of the bill and introduced it into the House of Lords this session for public information. The Earl of Balfour promised that the Minister of Health would consider the speech of Earl Russell, which would be particularly valuable in altering the attitude of the uninstructed public.

BILLS.

Mental Deficiency Bill.

Mr. Chamberlain informed Sir John Marriott that the Government did not propose to reintroduce the Mental Deficiency Bill this session. He understood Mr. Crompton Wood's bill would incorporate some provisions from the Government bill of last session.

The Lead Paint Bill.

In the House of Lords, on February 23rd, Lord Arnold opened a debate on the resignation of Sir Thomas Legge from the position of Senior Medical Inspector of Factories and to the Draft Regulations under the Lead Paint (Protection against Poisoning) Act. He reminded the House that in 1921 the representatives of thirty countries, including Great Britain, agreed to a draft convention whereby the use of lead paint for interior work was to be prohibited after 1927. The Lead Paint Act passed last year merely enacted that the use of lead paint for interior work should be regulated. Sir Thomas Legge, as one of the delegates of the

British Government, voted for the draft convention in 1921, and, looking upon what had been done by the Government as a breach of honour, he had resigned his position. For a civil servant to resign on a point of disagreement with the Government was unusual and serious. The vested interest of the white lead manufacturers had caused the Government to break faith. Sir Montagu Barlow had described the convention of 1921 as a settlement. Lord Arnold said that the harm done by lead paint in interior work mainly arose when old paint was rubbed down and particles of it got into the system through the lungs. Waterproof sandpaper was supposed to meet the danger, but so many things had to be done if waterproof sandpaper was to be a preventive that in practice all these things would scarcely ever be done. The Home Secretary had said in the House of Commons that Sir Thomas Legge did not wish to be concerned in the administration of the Lead Paint Act. That was not so. His main reason was that he could not recede from the position he had taken up in Geneva. Lord Arnold traversed the assertion of the Home Office that the draft regulations had been approved by various bodies, including the Operative Painters' Society. The regulations were nearly all drafted to apply to external painting, and were approved by the various bodies in 1922, when they understood that the Geneva Convention was to be ratified. The Government ought to make plain to the white lead manufacturers that it was to their interest to begin as soon as possible the manufacture of zinc paint and other substitutes for lead paint.

Lord Burnham said that, as chairman of the Drafting Committee, he was in part responsible for the convention. He regretted that the Government had been unable to recommend Parliament to ratify it. The contest at Geneva had not been between humanity and callousness, but between lead-producing and zinc-producing countries. It was quite open for any Government to recommend or not to recommend the adoption of a draft convention. He believed that the Act passed last session would have some effect for good, but that after it had been tried a draft convention would again have to be proposed for the consideration of Parliament. To try to make partisan capital out of the resignation of Sir Thomas Legge was monstrous: nobody who knew his work could feel anything but the highest respect for him.

Lord Haldane condemned the attitude of the Government. Lord Desborough, replying for the Home Office, joined in expressing the appreciation of that department, and of employers and employed, in the inestimable services of Sir Thomas Legge over a long period. His resignation could not have been postponed, but it was none the less to be regretted. There had been conferences with employers and employed about the regulations, and the Home Office was going carefully into the question of protection by, for instance, prohibiting the use of any lead paint in the form of spray. He thought the regulations would shortly be issued. After further discussion, Lord Arnold withdrew his motion for papers on the subject.

Research into Diseases of Animals.

In moving the second reading of the Diseases of Animals Bill in the House of Lords, on February 24th, Lord Bledisloe said one clause in the bill was to permit the use of an immunizing agent on contact animals in the event of an outbreak of rinderpest. This country had not had any such outbreak since 1887, but in South Africa, Japan, and Palestine an immunizing agent had proved effective. The work of the veterinary staff of the Ministry of Agriculture had achieved results of great value against foot-and-mouth disease. In 1923, the peak year, 1,929 outbreaks of that disease in this country involved a public expenditure of £2,205,000. In 1926 the number had shrunk to 204 outbreaks, with an expenditure of £1,389,000. This year there had been 19 outbreaks. The tracing of the Lanarkshire outbreak of last May to pig carcasses from the Continent had established a previously unknown source of infection. Meanwhile, outbreaks on the Continent had increased in number. The Foot-and-Mouth Disease Research Committee, over which Professor Martin now presided, had established that the claim of Drs. Frosch and Dahmen in 1924 to have isolated the micro-organism of the disease was not well founded. So far, the Committee had found it impossible to cultivate the virus and prepare an immunizing serum. They had experimented on the susceptibility of the virus to disinfectants, including vinegar, but by far their most important discovery was the vitality of the germ of the disease. In animal flesh the virus became inert within twenty-four hours; in the blood it remained active for thirty to forty days; and in bone marrow for seventy-six days after slaughter. An Order was about to be issued compelling the boiling of slaughterhouse offal before it was used for the feeding of pigs. The bill was read a second time.

Hours of Labour.

On February 28th the House of Commons discussed in Committee a vote of £11,653,564 for the Ministry of Labour. Mr. Hayday moved a reduction of £100, and called attention to the failure of the Government to ratify the Washington (Hours) Convention. Sir A. Steel-Maitland (Minister of Labour) said that the matter was under the consideration of the cabinet. Dr. Vernon Davies said he was a confirmed and convinced believer in the necessity, in the interests of efficiency, for a forty-eight hours' week. He suggested that the Minister might ratify the Convention provisionally, and that if, after a certain time, other nations did not ratify, Great Britain should repeal it. The Government front bench showed a lack of understanding of industrial psychology, and the very fact of ratifying the agreement would cause such a feeling of thankfulness and relief among the working people that there would be peace in industry. The amendment was rejected.

Vaccination and Small-pox.—In a reply to Mr. Groves, Mr. Chamberlain said severe reactions following vaccination had been reported at Sheffield and other towns. A medical officer of the Ministry of Health recently made inquiries into the results of vaccination at Sheffield on behalf of the Vaccination Committee which was now sitting. In another reply to Mr. Groves, Mr. Chamberlain said 10,158 cases of small-pox were notified in England and Wales during 1926; this total was subject to revision. In the year 19 deaths were registered in respect of which small-pox appeared on the certificates as the cause or one of the causes of death. The words "vaccination" or "vaccinia" appeared upon four medical certificates, but in three was subsequently withdrawn by the certifying practitioner.

Epidemic Diseases in Sheffield.—In figures supplied to Mr. A. V. Alexander the Ministry of Health shows that in Sheffield 58 cases of small-pox were notified during December, 297 during January, and 124 from February 1st to 19th. No deaths were notified. From November 28th to January 19th in Sheffield 398 cases of scarlet fever were registered with 5 deaths, and 296 of diphtheria with 13 deaths. No deaths were registered from measles.

Scarlet Fever.—Mr. Chamberlain told Mr. Bennett that the serum treatment of scarlet fever and the Schick test and von Behring's method of immunization against diphtheria were being used increasingly throughout the country and with encouraging results. He was advised that the serum treatment of scarlet fever was of value particularly in severe cases and in preventing complications. A fair number of local authorities now provided active immunization against diphtheria for those who wished to avail themselves of it.

Medical Examination of Boys in Coal Mines.—Dr. Vernon Davies asked whether boys were allowed to work underground in coal mines without previous medical examination, and whether the Ministry of Labour would take steps to see that they underwent a medical examination similar to that which children underwent under the Factory Acts. Mr. A. M. Samuel, replying for the Minister, undertook that the suggestion would be put before the right department.

Nurses' Salaries.—The Minister of Health, answering Mr. G. Hurst, said that the salaries paid to nurses in some of the public health services were not commensurate with the duties performed. In cases which came under his jurisdiction representations were made to the local authorities concerned. An association of nurses was consulted before the issue of the regulations of February, 1925, on the position of health visitors employed by local authorities. It was not at present proposed to revise these regulations.

Pension Procedure.—Major Tryon told Dr. Drummond Shiels that the duty of the Deputy Commissioner of Medical Services was to prescribe whatever treatment he considered necessary. When attention from a general medical practitioner was all that was required, the pensioner was advised to consult his panel doctor. Major Tryon did not feel justified in requiring, as Dr. Shiels suggested, the hospital treatment of all cases of deterioration. A certificate from the pensioner's own doctor was taken in support of a need claim, but if this was insufficient to enable the Ministry of Pensions to decide the claim, an examination was made by a medical officer of the Ministry.

Indian Medical Service.—On February 28th Earl Winterton (Under Secretary for India), replying to Mr. Pethick-Lawrence, who asked if a decision had been reached about granting passage concessions to Indian officers who entered the Indian Medical Service by competitive examination in London, said the Secretary for India expected that details of the scheme recently sanctioned would be announced shortly.

Notes in Brief.

From the armistice till March, 1927, £647,000,000 has been spent by Great Britain on war pensions, including medical treatment but excluding administration.

The Minister of Health is considering representations regarding the admission of road casualties into Poor Law institutions.

The Home Secretary does not contemplate amending legislation relating to compensation for silicosis.

On the ground that traffic considerations must come first, the Home Secretary maintains the prohibition against the processions organized by the West London Amalgamated Hospital Society.

The cost of medical inspection and treatment of children attending public elementary schools under the London County Council in 1926-27 is estimated at £201,555.

Fourteen schools in the Wigan area have been placed on the "black list," and the Minister of Education has received proposals for improving eleven of them. A report by Dr. Henry Whitehead has condemned the heating, ventilation, and sanitation of the majority of Wigan schools.

The Scottish Board of Health is communicating with the Parish Council of Uig about a rearrangement of medical practices in the parish.

A bill to prohibit the building over of London squares has been introduced by Mr. Scurr and read a first time.

Mr. Chamberlain is not aware that insurance practitioners generally charge fees to patients for dental services, though isolated cases may occur. Complaints should be referred to the local Insurance Committee.

On January 1st 116,748 persons certified under the Lunacy Acts were resident in England and Wales, and also 22,739 mental defectives in homes or under guardianship.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on February 19th the following medical degrees were conferred:

D.M.—V. S. Hodson.
B.M.—D. A. Robertson, C. S. Broadbent, M. D. Bower.

UNIVERSITY OF LONDON.

THE SENATE.

The Coming Election.

SIR WILLIAM COLLINS has informed the London County Council that he does not wish to be reappointed its representative on the Senate when his term of office expires next May. Sir William Collins has explained his reason in the following statement to the Education Department of the L.C.C.:

"The University of London Act, 1926, which, by appointing commissioners to effect, during the current year, the reconstitution of the University in general accordance with the report of the recent Departmental Committee, has, as you are aware, altered the relation of the L.C.C. to the University. The L.C.C. is no longer to be represented on the Senate, but on a Finance Council, and the Senate is no longer to be, as it has always hitherto been, the supreme governing and executive authority of the University, and is to be otherwise modified in its constitution and powers. This being the case, the L.C.C. may well desire to consider the advisability of finding a new representative for this entirely new position. As you may have gathered from the very pleasant interview which I had with your Higher Education Committee last summer, I view with mistrust and misgiving some of the changes which are about to be imposed upon the University. I do not desire to seek nomination to the new position."

Sir William Collins has represented the London County Council on the Senate for twenty-seven years, and for seven years before that was a representative elected by Convocation. It is reported that Lord Justice Atkin and Sir Robert McCall, K.C., will also cease to be members of the Senate.

At the forthcoming election of a medical member of Convocation to a seat on the Senate, Mr. W. McAdam Eccles, M.S., M.B.Lond., F.R.C.S.Eng., has consented to stand. He has, we are informed, strong support, and his long experience as a member of the Council of the Royal College of Surgeons of England, and as a member of the Council of the British Medical Association, should make him a suitable candidate. The vacancy is created by the expiration of the term of office of Dr. R. A. Young, who does not intend to offer himself for re-election. Members of Convocation must vote before or on Tuesday, May 10th.

Matriculation.

At the January matriculation examination 147 candidates passed in the first division and 779 in the second division; 63 took the supplementary certificate for Latin.

Appointments.

Professor G. Elliot Smith has been appointed the representative in respect of University College at the celebration in London of the centenary of the birth of Lord Lister on April 5th. Sir William J. R. Simpson will represent the University at the thirty-eighth congress of the Royal Sanitary Institute at Hastings in July, and Sir Holburt Waring has been appointed one of the representatives at the second International Congress of Byzantine Studies, to take place in Belgrade in April.

Sir StClair Thomson has been appointed a Fellow of King's College.

Two lectures on the history of medicine, illustrated by lantern slides, will be given at University College Hospital Medical School by Dr. Charles Singer, on March 11th and 18th, at 4.15 p.m.; they will deal respectively with the hygienic idea in world history and the history of yellow fever.

The Cancer Hospital (Free), Fulham Road, has been admitted as a school of the University under Statute 74 for three years from March 1st, 1927.

UNIVERSITY OF ABERDEEN.

AT a meeting of the Senatus on February 22nd it was agreed to confer honorary degree of LL.D. upon the following members of the medical profession on March 23rd: Professor Matthew Hay, M.D., Sir Frederick Gowland Hopkins, D.Sc., F.R.S., F.R.C.P., Sir William Milligan, M.D., and Mr. Charles Howard Usher, F.R.C.S.

UNIVERSITY OF MANCHESTER.

THE resignation of Professor W. W. C. Topley from the chair of bacteriology and the directorship of the Public Health Laboratory has been accepted by the Council as from September next, when Professor Topley will take up his duties as professor of bacteriology and immunology in the new London School of Hygiene and Tropical Medicine.

The Council has expressed its congratulations to Professor J. S. B. Stopford, professor of anatomy and dean of the Medical School, Professor T. Graham Brown, formerly lecturer in experimental physiology in the University, and to Dr. J. W. Mellor, a graduate of the University, on their nomination for election as Fellows of the Royal Society.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—L. G. Briggs, J. D. Evans, L. J. Lawrie, A. W. Marsden, J. H. Mulvany, W. D. Neill, L. W. Rose, R. S. S. Smith S. le R. Switzer, H. N Walker.

MEDICINE.—L. Ashkenza, B. Best, I. G. Briggs, J. de Rosa, J. A. Fernandez, S. Jenkinson, R. Kahn, J. H. Mulvany, H. Rundstrom, H. N. Walker.

FORENSIC MEDICINE.—P. V. Bamford, I. G. Briggs, J. de Rosa, R. Kahn, J. H. Mulvany, S. Wray.

MIDWIFERY.—I. G. Briggs, J. D. Evans, K. E. Gallacher, R. Kahn, J. H. Mulvany, S. Siotar, H N. Walker, R. W. Wood, S. Wray.

The diploma of the Society has been granted to Messrs. B. Best, I. G. Briggs, J. H. Mulvany, L. W. Rose, H. Rundstrom, R. S. S. Smith, S. Wray.

Medico-Legal.

AN OSTEOPATH'S CLAIM FOR FEES.

UNDER the Medical Act, 1858, Section 32, "no person shall be entitled to recover any charge in any court of law for any medical or surgical advice, attendance, or for the performance of any operation, or for any medicine which he shall have both prescribed and supplied, unless he shall prove upon the trial that he is registered under this Act." Notwithstanding the clear terms of this section, an osteopath sought last week to recover £30 9s. from a boxing referee and timber merchant, for professional services as osteopath to the defendant's wife. The case was heard in the Bloomsbury County Court by Deputy Judge Stoker, and was reported in the *Times* of February 25th.

According to the plaintiff, the defendant's wife came to him on March 10th last, stating that she desired osteopathic treatment. He observed that she was suffering from nervous debility and facial neuralgia, and found that one of her legs was longer than the other and contributed to the debility. His fees were 3 guineas for each consultation and 2 guineas for each subsequent visit. He obtained his osteopathic degree in America; he made no claim to be legally recognized in this country.

For the defendant it was argued that there had been improper treatment, and that the plaintiff was not qualified.

The Deputy Judge expressed the view that the plaintiff was prevented by the Medical Act of 1858 from recovering payment for medical or surgical treatment. Upon the plaintiff interposing that he did not claim to be giving medical or surgical treatment, the Judge rejoined: "The question is whether you do so. You are not registered under the Medical Act, which states that you must have a special qualification in order to entitle you to recover fees." He thought the plaintiff's case failed, and that he was precluded under the Act from recovering his fees in a court of law.

Judgement was accordingly entered for the defendant, with costs, with leave to appeal if desired.

Medical News.

IT is announced that the Canton Government has now taken over the John Kerr Hospital for the Insane from the charge of Dr. Selden, who has been working in Canton for thirty years. We referred last week (p. 392) to the recent difficulties experienced by this institution in carrying on its very important work.

PROFESSOR VITTORIO PUTTI, director of the Rizzoli Orthopaedic Institute, Bologna, will deliver the Lady Jones lecture in the medical school of the University of Liverpool on Thursday, March 10th, at 4 p.m. The subject of the lecture is "New conceptions in the pathogenesis and treatment of sciatica."

THE second of two Chadwick public lectures on rheumatism, its causes and prevention, will be given by Dr. Carey F. Coombs, physician to the General Hospital, in the Barnes Hall, Royal Society of Medicine, 1, Wimpole Street, W., on Thursday, March 10th, at 5.15 p.m., with Sir James Crichton-Browne, M.D., F.R.S., in the chair.

THE annual meeting and conference of the British Hospitals Association will be held at Norwich on Thursday and Friday, June 23rd and 24th. The honorary secretary of the association is Mr. J. Courtney Buchanan, C.B.E., Stapley House, 33, Bloomsbury Square, W.C.1.

THE microscopy of the living eye will be the subject of a paper to be read to the Optical Society on Thursday next by Mr. Basil Graves, M.A., M.R.C.S. The meeting will be held at the Imperial College of Science, South Kensington, at 7.30 p.m. Messrs. Clement Clarke will show an ophthalmoscope attachment to the Fincham slit lamp and the Cambridge Scientific Instrument Company its photographic ophthalmoscope.

DR. KENNETH BRUCE ALLAN, senior medical officer, West Africa Medical Staff, Gambia, has been appointed a member of the Executive Council of the Gambia and an official member of the Legislative Council of that colony.

MR. JOCELYN SWAN will lecture for the Fellowship of Medicine on the suppression and retention of urine at the Medical Society, 11, Chandos Street, W., on March 10th, at 5 p.m. On March 8th Mr. Gabriel will give a demonstration in clinical surgery at St. Mark's Hospital, City Road, at 4.30 p.m. The lecture and demonstration are free to members of the medical profession. The Hospital for Consumption and Diseases of the Chest, Brompton, will hold an all-day course of demonstrations for one week, starting on March 7th. A special course in orthopaedics will be given at the Royal National Orthopaedic Hospital from March 21st to April 2nd, with a visit to the Brockley Hill Country Hospital. From March 14th to 26th the Chelsea Hospital for Women will hold a course in gynaecology. A course in general medicine and surgery, primarily intended for general practitioners, will be held at the London Temperance Hospital from March 21st to April 2nd in the late afternoons. At the Queen's Hospital for Children, Bethnal Green, there will be an all-day course in diseases of children from March 28th to April 9th. In the afternoons only, for two weeks, from March 28th the Royal Eye Hospital will give a series of demonstrations on the diagnosis and treatment of eye diseases. Copies of all syllabuses and of the *Post-Graduate Medical Journal* may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A VACATION course in pediatrics will be held at the Hôpital des Enfants-Malades in Paris from April 20th to 30th, the fee being 200 francs. Recent researches and methods will be dealt with, including those relating to cerebro-spinal meningitis, scarlet fever, infantile asthma, the prevention of infantile tuberculosis, congenital syphilis, and the thyroid syndromes. Further details may be obtained from the Secretary of the Faculty of Medicine, 149, Rue de Sèvres, Paris (XVe).

UNDER the auspices of the Society of Hydrology and Climatology of Nancy and the Vittel Society of Medicine a congress on the gouty diathesis will be held at Vittel on June 5th and 6th, over which Professor P. Carnot of Paris will preside. Further information may be obtained from M. Renard, Société générale des Eaux, Vittel, Vosges.

AT a council meeting of the Society of Members of the Royal College of Surgeons of England a resolution was passed unanimously deploring the great loss sustained by the death of Mr. C. Edward Wallis, M.R.C.S., L.D.S., and placing on record its appreciation of his untiring zeal and self-sacrificing service on behalf of the society and all the Members of the College.

THE Council of Epsom College is about to award a St. Anne's Home Scholarship of £52 a year to the orphan daughter of a medical man who had been in independent practice in England or Wales for not less than five years. Candidates must be fully 7 years of age and not over 12 years on May 1st next. The Council is also about to award a Henry Duncalfe Annuity of £30 a year to the unmarried daughter of a medical man. Candidates must not be under 50 years of age. Forms of application can be obtained from the Secretary, at the Office of the College, 49, Bedford Square, W.C.1, and must be returned not later than the morning of March 16th.

DR. R. A. MILLIGAN, who recently retired from the position of surgeon to the Northampton General Hospital after more than forty years' service, has been presented with a cheque for £453 and an album containing the names of the subscribers to the testimonial fund.

A BAS-RELIEF bronze bust has been placed in the main hall of Leeds General Infirmary as a memorial to the late Mr. Walter Thompson, for many years honorary surgeon to the institution.

THE Ministry of Health has published a report (No. 39) on the determination of benzoic acid in foodstuffs, which has been prepared by Dr. G. W. Monier-Williams. In addition to a review of the literature on the subject and discussion of the difficulties associated with the methods of analysis, various laboratory investigations are considered. The report, which is intended especially for public analysts and chemical advisers to industrial concerns, may be obtained from H.M. Stationery Office, or through any bookseller, price 1s. net.

THE Rockefeller Foundation has made a further grant of 75,000 dollars to the German Research Institute for Psychiatry at Munich, to which it contributed 250,000 dollars last year.

THE issue of *Hospitalstidende* for January 20th contains a memoir, by Dr. Carl Sonne, of the late Danish surgeon Professor Thorkild Rovsing, with a bibliography of his scientific writings.

THE Bureau of the Far East at Singapore reports that during the week ending January 22nd there were 33 cases of plague with 16 deaths, 66 cases of cholera with 65 deaths, and 306 cases of small-pox with 91 deaths.

FOR the purpose of binding in two parts the *Proceedings of the Royal Society of Medicine* for 1925–26 (vol. xix) there is now available a main title-page for each of the two sub-volumes; a special title-page and list of contents for the reports of general and joint discussions; a title-page and contents for the reports of each of the Sections, in case it is desired to bind these separately; and a general index. Binding cases may be obtained, post free, from Messrs. John Bale, Sons and Danielsson, Ltd., for the whole year's *Proceedings* in two parts 6s., and for separate Sections 3s., each. These publishers are also prepared to bind any single Section for 4s. 6d., or the whole *Proceedings* in two parts for 10s. 6d.

ON page 445 of this issue appears an announcement by the War Office regarding temporary commissions in the R.A.M.C. for home service. As we go to press we are informed by the Army Medical Department that the response to this notification has been so satisfactory that enough applications have already been received to fill all existing vacancies.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediseera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

MR. W. F. HAMILTON (St. Leonards-on-Sea) asks whether unsatisfactory results have been found to follow the use, in the preparation of the skin for surgical operations, of a solution containing 1 per cent. each of crystal violet and brilliant green in a mixture of rectified spirit and water. He states that he has known blistering to occur and also some delay in skin union, even in aseptic wounds.

CHRONIC URTICARIA.

"PRURITUS" would be glad of suggestions in the treatment of a case of chronic urticaria in a woman aged 50. The condition has lasted several months, in spite of careful dieting, administration of intestinal antiseptics, and calcium chloride and lactate; externally, soothing lotions and exposures to *x* rays and artificial sunlight—all with no beneficial effect. The patient looks healthy, though suffering from disturbed sleep, and the urine is free from sugar and albumin.

INFECTION IN BAKERIES.

A MEDICAL CORRESPONDENT (Scotland) relates that he has been concerned in the following case: A working baker employs several workpeople; two of them were removed to hospital suffering from diphtheria, and within a week a third developed a sore throat. Our correspondent asks what section of the Public Health Act covers the matter.

*** The baker would not, as such, under the Public Health (Scotland) Act, 1897, be required to intimate the occurrence of sore throat in his third employee to the medical officer of health. If, however, the working baker happened to stand to his third employee in one of the relations specified in Section 3 (1) (*a*) of the Infectious Disease (Notification) Act, 1889, and if at the same time he was aware that his third employee was, in fact, suffering from diphtheria, he would, in these circumstances, but not otherwise, be required to send a notice to the medical officer of health. Action might possibly be contemplated against the employer under Section 16 (6) of the Public Health (Scotland) Act, 1897, which says that any trade or business so conducted as

to be injurious or dangerous to health shall be deemed to be a nuisance; or against the employee under Section 58 of the same Act and the amending Act of 1907 for engaging in an occupation connected with food, provided he knew that he was, in fact, suffering from diphtheria and did not take proper precautions. But a local authority proposing to go to court under any of the sections cited would probably be expected to prove, not merely negligence on the part of those concerned, but deliberate suppression of the facts, and also to show that its own officers, by visit, inquiry, and otherwise, had exercised due diligence to keep in touch with the progress of events at the bakery.

THE ACTION OF UROTROPINE.

DR. ROBERT ANDERSON (Erdington, Birmingham) writes: I would ask two questions with regard to the action of urotropine. (1) How can it act as an antiseptic in one part of the body only in an acid medium and in another in an alkaline one? (2) If its action in the first instance depends on its decomposition by an acid, how does it escape decomposition by the hydrochloric acid of the stomach? In the BRITISH MEDICAL JOURNAL, October 16th, 1926, Dr. Hurst states that urotropine has been proved to act as an antiseptic in alkaline bile. It is not generally known that urotropine is a cause of dermatitis in rubber workers. Such cases nearly always occur during hot weather, when the workers perspire freely. The acids of the perspiration are supposed to decompose the urotropine.

*** The action of urotropine is rather a puzzle at present. It is a definitely ascertained chemical fact that urotropine only undergoes decomposition into formaldehyde in an acid medium; for example, only 1 per cent. is split up into formaldehyde in an hour in a feebly acid solution (pH^6). At an acidity corresponding to that of the stomach contents (pH^2) about 30 per cent. of urotropine is split up in an hour. It is generally agreed that urotropine has no disinfectant action until it liberates formaldehyde. The action of urotropine in producing disinfection in an acid medium—for example, acid urine—is well established and understandable from the above facts. It is known, however, that the amount of action produced varies considerably in different persons, and this is believed to be due to the varying quantity of the dose administered which is split in the stomach contents. Any portion of the drug which was split up in the stomach contents would be rapidly neutralized by reaction with the neighbouring tissues. Pharmacologists have generally declined to believe that urotropine acts as a disinfectant in neutral or alkaline media, such as the bile or cerebro-spinal fluid. In recent years, however, evidence has accumulated that urotropine can act as a disinfectant in the bile. The evidence for this is strong, although perhaps not quite conclusive. The only explanation of this phenomenon that we have come across is that the bacteria living in alkaline media may produce small amounts of acid and so the immediate surroundings of each bacterium may be faintly acid. According to this theory urotropine would be split up when it met the bacteria, and the liberated formaldehyde would kill the bacteria. It is very difficult to prove or disprove this hypothesis, but it seems to be the only one at present that at all meets the facts.

EPIPHORA.

DR. A. C. [illegible] verness-shire) writes: In answer to Dr. A [illegible] bruary 26th, p. 410) I understand that Pa [illegible] ly have one solution—that is, 1 in 1,00 [illegible] iven for 1 in 10,000 are 1 fluid drachm [illegible] chloride and 9 fluid drachms of physiological salt solution, so that the one drop in 16.6 oz. of water is not necessary for the correct dilution.

LETTERS, NOTES, ETC.

TREATMENT OF TETANUS BY INTRATHECAL INJECTION.

DR. M. ALLAN (Patricroft) writes: I read with much interest Dr. Bertram Muir's communication (JOURNAL, January 29th, p. 186) on the treatment of tetanus by intrathecal injection of antitoxin. As clinically and experimentally (as shown by Bruce) it can be demonstrated that intrathecal injections are of undoubted benefit, we need pay little attention to the failure of the laboratory to explain the fact. I have seen two cases of tetanus: one was in a carpenter who had received a lacerated wound by a flying splinter of wood to his right thenar eminence. He was treated by intramuscular injections, but death resulted three and a half days after admission to hospital. The other case was in a hide worker, the origin of the injection being in a septic wound of the left thumb. Profiting by my former experience, I gave on the first day 20,000 units intrathecally, together with a similar dose into the body of the vastus externus muscle. On the following day, under general anaesthesia, a similar dose was given, and thereafter the blood stream kept saturated with antitoxin by means of intramuscular injections. Recovery was rapid and uneventful. I do not agree with Dr. Muir that there was anything to be gained in his case by intrathecal injection at the anatomical site of the anterior horn cells of the spinal cord. Even when an early diagnosis is made the toxin has spread far and wide, and after the intrathecal injection I prefer to elevate the foot of the patient's bed and remove the pillow for two hours in order to flood the higher and more important centres with antitoxin.

THE DANGEROUS JUNKER.

DR. H. G. DODD (Hove), referring to Mr. W. J. Foster's condemnation of the use of valveless Junker's inhalers (JOURNAL, February 5th, p. 261), mentions a description by himself in the *British Journal of Anaesthesia* for October, 1926, of a modification of Junker's inhaler, in which the inlet tube is straight and extends nearly to the bottom of Buxton's bottle, its lower extremity being tipped with bone, as in the older models. A ball valve is fixed to the afferent tube outside the bottle, close to the attachment of the rubber tubing from the hand bellows, as suggested by Rigby. It is claimed that this modification, while being free from danger, is without certain disadvantages found in the Rigby type of inhaler.

FOG FLARES FOR MOTORISTS.

AS the result of experiments in the use of flares at road junctions during dense fogs, the Automobile Association has recently established a service of fog flares at some fifty roadside points. When a dangerous fog occurs, obscuring these road junctions, the patrols light the flares and keep them alight during the day, and, if necessary, after dark until ordinary traffic ceases. It is stated that this new service was much appreciated during the recent fogs.

THE IDEAL HOME EXHIBITION.

THE popular annual event, the *Daily Mail* Ideal Home Exhibition, was opened on Tuesday by the Hon. Mrs. Esmond Harmsworth. Within the walls of Olympia many new ideas for making the life of the housewife easy and healthy have been collected. It is possible that labour-saving devices bring with them their own troubles; on the path of progress the human mind does not always keep step with human invention, and the female domestic is quite capable of upsetting the calculations of the most ingenious inventor. Nevertheless, the completeness of equipment of the houses in the "Village of New Ideas" in the New Hall Extension, with its range of buildings from a Tudor manor house to a £850 cottage, will impress the visitor. An exhibition of healthy homes does not, of course, contain many objects that are purely medical. The Scholl Manufacturing Company exhibits some of its appliances for foot ailments, while the Dowsing Radiant Heat Company shows many methods of application of light and heat, including equipment for the dubious purpose of home use. The use of ultra-violet rays is illustrated by a working model of the new monkey house shown by the Zoological Society. The air is not directly heated, the monkeys being kept warm by sitting on floors heated by electric heaters. The roof of the house is entirely glazed with "Vitaglass," while in dull weather the supply of ultra-violet rays is [illegible] descent electric lamps made of "[illegible]" products exhibited are numerous, and cookery is included. Concentrated foods, such as Horlick's Malted Milk, Wander's Ovaltine, and Glax-Ovo are available for the [illegible] drinker can investigate the advantage [illegible] Softeners Company's "Permutit"; soils [illegible] can be wrung and mangled in the home by Messrs. Gamage's "Referee" wringer; water-closets can be cleaned and deodorized by the Lewbart Automatic Cleanser; and the housewife need only polish her stove once a year, according to the Mond Staffordshire Refining Company, if she uses "Melanoid."

COAT LININGS.

THE lining of coats, particularly of overcoats which may have to be taken on and off frequently during a round of visits, is a matter of some consequence to medical men. An advertisement of Courtaulds' linings appears this week. The artificial silk of which these materials are made has, as is well known, most of the qualities of silk, and has in particular the slippery surface desired in linings. Further particulars can be obtained from Messrs. Courtaulds Limited, Department 139M, 16, St. Martin's-le-Grand, London, E.C.1.

SIR JAMES MACKENZIE'S LATER VIEWS ON THE NATURE OF CARDIAC ACTION: CORRECTION.

WE regret that, owing to a printer's error, the word "node" was substituted for "muscle" in line 29 of the report of the meeting of the James Mackenzie Institute on February 1st (BRITISH MEDICAL JOURNAL, February 19th, p. 333, col. 2). The sentence, which begins in line 25, should read as follows: "As regards the spread of the excitation wave through the auricle, the balance of evidence, having regard to direction and spread and rate of transmission, was greatly in favour of a spread through the auricular muscle." This was one of the main points of Dr. Orr's address.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 83.

Milroy Lectures

ON

HEALTH HAZARDS IN THE COTTON INDUSTRY.*

BY

WILLIAM FRANCIS DEARDEN, M.R.C.S., L.R.C.P., D.P.H.,

MEDICAL OFFICER OF HEALTH, PORT OF MANCHESTER; CERTIFYING SURGEON.

(Abridged.)

[In some preliminary observations Dr. Dearden quoted figures from the Registrar-General's occupational mortality tables, also mortality figures relating to Blackburn weavers, compiled by Dr. A. Greenwood and published in 1907, and Dr. W. A. Daley, published in 1923, to show the diminution in mortality among cotton operatives over certain periods, the relatively higher incidence of certain diseases (bronchitis and diseases of the circulatory system) among them, and the improvement in the health of the weavers, particularly during the last thirty years. He further quoted some morbidity figures which he had himself compiled from the records of the Card and Blowing-room Operatives' Society, based on more than 10,000 cases of sickness causing absence from work during 1922-24; these showed an excessive sickness incidence from bronchitis, pneumonia and pleurisy, rheumatism, influenza and colds, tonsillitis, and digestive troubles. His conclusion was that the health of all classes of cotton operatives was steadily improving, but that the various branches of the industry still exhibited a definite partiality for particular diseases and ailments.]

Atmospheric Conditions in Cotton Factories.

Having arrived at certain conclusions regarding the diseases and ailments to which operatives in the cotton industry are particularly liable, we have to consider the various factors which can be shown to account for the excessive and selective susceptibility. The successive processes to which cotton is submitted in the course of conversion from vegetable down to plain cotton cloth demand certain definite atmospheric conditions. As the processes are operated under control by, and with certain assistance from, the human element, man and machine working together in the same confined space, it would appear essential that these atmospheric conditions should be so arranged as to be equally satisfactory to both the factors concerned. Considerable headway has been made in this direction since the close of the last century, but there are still difficulties to overcome before the ideal relationship is reached. I am satisfied, however, that the proposition is practicable, and I hope in what I have to say fully to support this optimistic statement.

In dealing with the influence exercised by temperature and humidity in cotton manufacturing processes, I propose to treat the subject, in the first place, from the cotton point of view, and afterwards from the human aspect. I will then endeavour to show where the two interests conflict, and what can be done to bring them into line.

The Requirements of the Process.

Geographically our cotton towns and their surroundings occupy a dished-out area in the south-east of Lancashire, sheltered by the Pennine chain to the east and north, and by the Derbyshire hills to the south; only the west is open, and in that direction the land extends as a level plain to the sandy shores of the Irish Sea. There is thus ample protection from cold dry winds, and an open door to the temperate, moisture-laden breezes from over the water. The climate of this particular district is temperate, equable, and moist. The high percentage of moisture is due to the cooling influence of the hills on the warmer air of the plain, the relative humidity automatically increasing in proportion to temperature lost. The temperature of Blackburn is ordinarily about 2 degrees less than that of Liverpool, but the humidity averages rather more than 8 per cent. higher. The same conditions which produce a higher humidity percentage bring about an increase of the rainfall, but there is no closer relationship between the two.

Both spinning and weaving processes flourish best where there is little variation in atmospheric conditions, but weaving requires a higher relative humidity.

(a) *Spinning and Associated Processes.*

Under modern conditions the process of spinning requires a high temperature, which must be maintained as nearly as possible at one level throughout the year. This is due to the fact that by means of heat the individual fibres are rendered more pliable, and thus easier to spin, owing to the softening of their waxy content. The wax melts at about 80° F. Actually the temperature of a spinning room should be ruled by the class of "counts" going through at the time, but the effective temperatures range from 70-80° to 85-90° from the coarse to the fine counts. A certain amount of humidity is also required, and must be kept at an even percentage. Dry air makes the fibres brittle, interferes with their twisting properties, and produces a less uniform and weaker yarn. There is a limit, however, to effective moisture. In fine-spinning rooms it is found that a higher relative humidity than 50 per cent. interferes with the drawing out of the roving, though for coarse "counts," spun from cotton of lower quality and shorter staple, a humidity of 60 to 65 per cent. may be regarded as the limit.

In the preliminary processes of opening, scutching, and carding the natural atmosphere as modified by frictional heat is usually sufficient in Lancashire, except during cold weather, when the rooms are heated before beginning work. Card-rooms, where the process of carding, drawing, combing, and roving take place, have an ordinary working temperature of 70° to 75°, though some mills start work at much less than this without detriment, and even in July the temperature rarely exceeds 80°. The doubling of yarn is carried on under similar conditions of high temperature to those which obtain in spinning, and the heat may be very trying in the summer-time. As the practice has now become very general to drive the frames directly by electric motors, an additional source of heat comes into play, and at the same time air movement from running straps and pulleys is diminished. This means a greater call on ventilation. The common practice is to run the threads through water before twisting so that no question of artificial humidification arises. The natural atmosphere, with steam pipes for warming when necessary, and windows to open, meet the requirements for winding, reeling, beaming, and warping.

(b) *Weaving.*

In the early days of weaving cotton cloth by hand loom, high temperature was unobtainable, owing to the segregation of looms and the slow speed at which the process was carried on. Humidity, however, was an important condition, and a damp out-building or half-cellar was considered a good asset to the weaver. The advent of the mechanical loom, with the concentration of large numbers of these machines under one roof, and the increased speed at which they were driven, brought about the first change in the requirements for efficient weaving. A higher temperature in the weaving space was a natural consequence, and this was found to be beneficial by preventing breakages. The humidity percentage was lowered, but, with the aid of evaporation from the workers and the nature of the site usually selected, was found to be sufficient. Next came a demand from Eastern markets for a very cheap type of cotton cloth. To provide this at a profit meant high-speed production, and the loading up of the yarn with foreign material. The friction of the shuttle and reed against the warp at high speeds has a tendency to produce electrical trouble with the warp threads, and therefore an increase of humidity is called for to neutralize electrification and increase the tensile strength of the yarn. The earliest method of increasing the natural humidity was by the use of raw steam, and the factories in which this method was employed were known as "wet" sheds, in contradistinction to factories where artificial humidity was not required, which were known as "dry" sheds. The latter are said to number 61 per cent. of the sheds in

* Delivered before the Royal College of Physicians of London on March 1st, 3rd, and 8th.

this country, and there the better quality and more elaborate varieties of cotton cloths are produced.

Lander states that 70° F. is the most suitable temperature for weaving purposes. From numerous shed records I have examined it would appear that this need not be exceeded. In practice, however, high temperatures are the result to a large extent of demands for a high percentage of humidity and the utilization of steam, and this was particularly exemplified in the days when raw steam issuing from unlagged pipes was the sole method of providing this humidity. It is now generally agreed, according to Lander, that an average humidity of 78 per cent. is a reasonable amount for materials commonly woven in humid sheds. The popular view that the efficiency of the process in humid sheds, within certain limits, increases with the temperature or relative humidity is supported by Wyatt (1923), who considers that "under existing regulations the best conditions for productive efficiency in weaving in humid sheds of the type under investigation seem to be obtained with a dry-bulb temperature of 70° to 75° F., and a relative humidity of 80 to 85 per cent." In view of the divergence of opinion among manufacturers it would be the proper course, from the standpoint of weaving efficiency, to establish an experimental shed and make an exhaustive series of tests with a view to ascertaining the most suitable temperatures and humidities for warps of different tensile strengths and with varying percentages of size.

PHYSIOLOGICAL AND PHYSICAL CONSIDERATIONS.

[Dr. Dearden then recapitulated the known facts regarding the generation of body heat, the regulation of body temperature, and the reaction of the regulating mechanism to atmospheric and other external factors. He mentioned the observation of Haldane, who, experimenting with men stripped to the waist, found that the limit of wet-bulb temperature which could be endured in still air was 88° F. when resting and 78° F. when ascending steps; and of Vernon, who pointed out the influence of acclimatization in increasing the endurance. Air movement counteracted both the ill effects of rising atmospheric temperature on convection and the bad influence of humidity on evaporation. He then continued with a description of the kata-thermometer (for short the "kata"), an instrument designed by Professor Leonard Hill primarily for the measurement of its own rate of cooling when its temperature approximates to that of the human body.]

At an early period of his investigations Professor Hill recognized the importance of being able to obtain some definite indication of the extent to which the external atmosphere could carry out its function of removing the excessive heat generated by the living body. He therefore sought out a means of measuring atmospheric cooling power. The theory of the kata-thermometer appears to be that the rate and amount of heat lost from a given surface of a body at the same temperature as the human body should indicate fairly accurately the loss from an equivalent surface of the latter when exposed to the same atmospheric conditions. When the uncovered instrument is used the resulting figure shows the amount of heat dealt with by radiation and convection, and is known as dry kata cooling power; when the bulb is covered with a wet silk stall the calculated figure indicates in addition the heat lost by evaporation, and is known as the wet kata cooling power. The difference between the two results, when both methods are being used, indicates the cooling power exercised by evaporation only. This was followed up by ascertaining what dry and wet kata figures under fixed conditions of heat production correspond to atmospheric conditions yielding the greatest feeling of comfort to the individual. Hill has come to the conclusion that a dry cooling power of 6 and a wet cooling power of 18 may be taken as indicating the most suitable conditions when light work only is carried on. I do not insist that as standards these represent finality, and that they will not be subjected to some modification as the result of larger and more varied experiences; but I do recognize their present utility as standards, and the consequent facility they give for comparison of results; if the upsetting factors are known allowances can be made for them when gauging the atmospheric conditions. The clothing factor, for instance, is exceedingly variable. Hill found that a nake kata at 64.8° atmospheric temperature cooled two and half times faster in a mild breeze than in still air ; 61.3°, but that this rate was reduced to only 85 per cen increase when the thermometer was covered with a sil stall, and to only 46 per cent. increase when covered wit a woollen stall.

[Dr. Dearden also described an American system of assessin atmospheric conditions by the "effective temperature," b while appreciating its suitability to American systems ventilation, he was not convinced that it could substitute for t kata-thermometer under the conditions which had to be dea with elsewhere.]

THE MECHANICAL AND HUMAN INTERESTS IN ASSOCIATION.

(a) *Spinning and Associated Processes.*

I have now to show to what extent efforts have bee made to reconcile the apparently conflicting interests of th mechanical and the human element, the faults still needin rectification, and the further accommodating measure which must be devised. The Report of the Home Offic Committee on Ventilation of Factories and Workshop (1902) shows how much the manufacturing conditions an how little the human needs were studied not many year ago. The small number of mills that were reasonabl ventilated and the still fewer mills that had combine ventilating and humidity systems had even then satisfactor temperatures and humidities, but the large number—nearl all spinning fine "counts"—which were not ventilate at all had, without doubt, unnecessarily high temperature and humidities. Conditions have altered materially, an fine-spinning mills are now excellently provided wit mechanical methods for filtering the air and for regulatin the supply of air and the temperature and humidity. Dr and wet bulb thermometers are fixed up in the spinnin rooms, and thus the indications for any necessary adjust ments are provided. It is the custom to take regula readings twice a day, so that there are plenty of systematic records available for inspection and study. It has bee my privilege to analyse a ten years' complete record taken at a group of four mills.

[Dr. Dearden here showed charts giving the curves obtained in respect of temperature and humidity in several rooms over a period of one year.]

The graphs as a whole show how closely the temperature and humidity conditions are confined within the limits I have previously given. The afternoon temperatures are higher than the morning ones, and the humidity percentages are kept at a fairly even level throughout both the day and the year. In two rooms the daily variation is between 1 and 2 degrees, and the monthly variation is kept well within the same range in spite of seasonal changes. The other rooms, though also showing equable results over the greater part of the year, appears to have been readily influenced by outside temperature during the summer. Where this occurred it was discovered that the humidifying plant could be regulated from inside the rooms, while, in the rooms in which the temperature remained even, this interference was not possible. Spinners will try to regulate the water sprays in hot weather if they have the opportunity, and each spinner in the room has different views on the subject, though all of them appear to be fond of a high temperature.

The humidity question requires more consideration than appears at first sight. It is true that, for the sake of the cotton, the percentage is kept low, but the fact must not be overlooked that the maintenance of the desired proportion means the provision of a considerable amount of moisture over and above that of the outside air at the high temperature required for successful spinning, and that it is the quantity and not the percentage which concerns the operative. The charts show how exactly the wet-bulb temperature rises and falls with the dry-bulb temperature; in well conducted mills the former is always above 70°, and frequently above 75°.

Air movement receives little encouragement in spinning rooms where fine counts are being dealt with. The conditions are often such that there is no appreciable air

movement a few feet away from the duct openings through which the outside air, driven along one or more tubes running the length of the room, emerges at regular intervals; the air exits are the doorways, of which there are generally two to a room. To ensure no air entering by unauthorized routes a slight plenum is aimed at, and when this is exceeded the swing-doors are pushed outwards, the escape of air relieves the pressure, and the doors coming together again are ready for the next puff. The deficiency in sensible movement at high temperature is reflected in some typical examples of wet kata-thermometer readings taken in August, 1926, which also show that diminution in cooling power follows elevation of wet-bulb temperature when there is no undue interference by air currents:

D.B. temperature.	W.B. temperature.	Wet kata.
94°	78°	9°
89°	76°	10°
88°	76°	10°
89°	74°	10.3°

Standing four feet from a doorway with one of the swing-doors two-thirds open a wet kata cooling power of 10 advanced to 18.8, and the dry kata showed an air velocity of 75 feet a minute.

The clothing of spinning-room operatives is also a consideration. The male workers in the spinning rooms are quite suitably attired for the work in cotton shirt or singlet and cotton trousers or blue overalls, but the females are not always clothed so suitably. The latter may simply take off the outdoor dress and don an overall, and whatever is under the dress, whether little or much, on the worker arriving at the mill, remains under the overall. Where "welfare" is in vogue, however, supervisors have made strides in establishing a more rational dress. Both sexes have bare legs and feet.

The spinner has to put up with high temperature and humidity, and, in fine-spinning mills, with a low air velocity, all the year round. For a short period in summer these conditions, more particularly in coarse-spinning mills, are intensified. He is, however, well acclimatized to this atmospheric state, and unless the temperature is excessive or he indulges in extraordinary muscular effort, he usually keeps his own temperature equilibrium. In the colder months of the year the change to a much lower temperature on leaving work, particularly to the overclothed, explains the special susceptibility to colds and influenza. On the other hand, Dr. E. M. Brockbank of Manchester has noted that cotton operatives under 50 years of age enjoy a somewhat remarkable freedom from the ill effects of high blood pressure, possibly owing to the removal of waste products of metabolism by perspiration.

What are the methods to be adopted to prevent the ill effects I have described? In the first place, the temperature necessary for the particular "counts" being spun should not be exceeded, and in no case should be allowed to rise above 90°. It is generally recognized that sweating should be avoided. That the temperature can be satisfactorily regulated, even in fine-spinning rooms which require the higher range, is amply demonstrated. Mills spinning at the lower counts have a lower range of temperature, and are satisfied with the outside air unaltered. In summer, however, they are more affected by extreme heat and solar radiation than are the exactly regulated fine-spinning rooms, and the temperature may rise to 100°. This necessitates artificial humidity, and where humidifiers are installed these are started when breakages become too frequent. The remedy is an increased air movement, and this type of mill could be most conveniently supplied with propulsion fans and ducts to assist the windows; water vaporizers acting in conjunction would be a distinct advantage.

Every effort should be made to instruct females particularly as to the most suitable attire. With the uniform high temperature in the fine-spinning rooms, bloomers, singlet or blouse, and overall are quite enough to wear, and this applies to other varieties of spinning during the summer months, though a skirt and blouse may be added in the lower temperature rooms during the colder months.

With regard to the preliminary and subsidiary processes, in none of these is artificial humidity really required in Lancashire, nor, except in the doubling rooms, is the summer temperature excessive. As moderate air currents are not conducive to breakages or bad work, efficient ventilation by extraction fans with or without ducts can be safely utilized. Though some gassing rooms are still objectionably hot and stuffy, the modern variety are so efficiently provided with mechanical ventilation that the workers no longer suffer discomfort.

(b) *Weaving.*

Dry weaving sheds are not difficult to deal with, but wet sheds provide by no means an easy problem—a problem, by the way, which would not exist if manufacturers would so compound their warp size that artificial humidity would not be required. The cost of softeners and deliquescents in sufficient quantities is held to be prohibitive, and as moisture is not only effective as a softener but reasonably cheap to produce it seems unlikely that it will be superseded. Several sets of regulations have been produced with regard to excessive humidity in weaving sheds, and each set has marked a stage of improvement, each has placed a good "brick" in the protective wall around the worker, but I have formed the strong opinion that the most far-reaching effect is that produced by the compulsory standard of ventilation. The fact that this opinion was formed before the physical theory superseded the old chemical theory of ventilation does not affect my point. Quite a number of appliances for ventilation follow up-to-date precepts, and can deal with air either from inside or from outside the shed as desired.

An undue elevation of temperature invariably brings about adverse conditions affecting the individual. Legge found that weavers are subject to a rise in mouth temperature when the wet-bulb temperature exceeds 75°. Pembrey and Collis found elevation of temperature, quickened pulse and respiration, and lowered blood pressure when the wet-bulb temperature was much over 70°, and, like Legge, they noticed that the mouth temperature in women was consistently higher than in men, and this is ascribed to the greater amount of clothing worn. On the other hand, as the result of over 16,000 observations of body temperature in Indian mills, Maloney is of opinion that it is not possible to say that this begins to be adversely affected at a given wet-bulb temperature. Again, in addition to the chronic strain on the circulation from excessive peripheral blood supply during the eight hours of each working day having a tendency to diminish resistance, there is a susceptibility to chills on leaving work through the humid air at mill temperature having percolated shawls and coats hung up in the shed, as well as the clothes being worn.

The general principles, therefore, regulating the prevention of these ill effects are: reasonable temperature, suitable clothing, clothing kept dry whilst in the mill, and effective air movement.

[Here the lecturer summarized the 1911 Regulations (now approaching the out-of-date stage) in these respects. Whilst these had assisted prevention in many ways, the question of clothing was apparently out of their purview, and what was really wanted to effect a general hygienic practice in dress was a system of instruction by welfare workers or by leaflets. He also summarized Wyatt's report for the Industrial Fatigue Research Board (BRITISH MEDICAL JOURNAL, March 3rd, 1923, p. 389).]

The reports of both Wyatt and Maloney clearly indicate that, apart from other requirements, there should be means available for securing better air movement. In my opinion much could be done in this direction by fixing separate kata cooling standards for wet weaving sheds, though I am not prepared to say that Hill's standard for sedentary work would quite meet the case, but rather that the figures should be varied according to temperature. Something in the nature of 6 dry and 16 wet for temperatures below 70°, and 5 dry and 14 wet when above 70°, might prove reasonable.

DUST.

(a) *Sources and Nature of Dust.*

Just as high temperature and humidity constitute the principal menace to the health of the worker in spinning and weaving rooms, so in the preliminary processes of preparing the raw cotton for further manufacture the *principal militating factor is the* generation of dust. Whilst all processes in cotton manufacture are more or less dusty, those of mixing, opening up, and carding are subject to a specially objectionable variety which renders the workers liable to develop diseases dangerous to life. The amount of dirt contained in the raw cotton, which has to be removed, varies with the quality of the staple. Where *bale-breaking is still a hand process the worker has to put* up with a considerable quantity, but where the modern mechanical method is in vogue dust is not nearly so much in evidence. Although modern cards are enclosed, there are several points where dust escapes, so that in most card-rooms there is a tendency towards a hazy atmosphere. A considerable amount of noxious dust arises from the brushing of the flats, but the most intense clouds are produced by the stripping of dirt and waste from the carding and doffer cylinders. Up to quite recent times the process of stripping was carried out in the open, but owing to the modern provision of a closely fitting tin cover with an exhaust attachment this evil condition no longer obtains in Lancashire. The newer method of stripping is worked on the lines of the ordinary vacuum cleaner. The clearing of the waste and dirt from the receptacles beneath the cards, openers, and scutchers is also a very dusty proceeding.

The dust arising in cotton manufacture, though mainly "vegetable," contains, in the preliminary processes of preparation, during weaving, and in the manipulation of the finished cloth, a considerable proportion of mineral matter. In breaking up the bales the dusty product consists mainly of short fibres. The opening and scutching processes bring away a considerable quantity of seeds, husks, and sand. Carding produces a dust made up of short and knotted pieces, seeds, broken husks, and, again, much fine sand.

Mill operatives in the carding and blowing departments are particularly liable to bronchitis. Cleaning out the dirt boxes beneath the machines, and, to a lesser degree, leaky brush covers, are in my experience the factors mainly responsible for this susceptibility. The symptoms one notices in strippers at work are undoubtedly those of asthma. There is pronounced dyspnoea, which is distinctly asthmatical in character and of a thoracic type, also a dry irritative cough, and a small but very sticky expectoration. A very noticeable feature of the complaint is the complete disappearance of the symptoms during the week-end at home. In imperfectly ventilated gassing rooms the atmosphere is quite hazy from the charred particles floating about, and the odour of burnt cotton is disagreeably pronounced. The dust is very irritating, and I find that girls suffering from blepharitis or subject to conjunctivitis or catarrhal conditions of the respiratory mucous membrane are markedly affected. Workers in ordinary health, however, soon get acclimatized, though among some I notice a distinct tendency to anaemia and a liability to headache, dizziness, and lassitude—symptoms which in my view are the result of imperfect removal of the unburnt products of the Bunsen gas flame.

(b) *Preventive Measures.*

In the preliminary breaking up and decompressing of the raw cotton, dust is very successfully prevented from polluting the atmosphere by the unbroken bales being placed directly into the hopper of the bale-breaker in the first instance, and subsequently conveying the cotton to the openers by exhaust ducts. In most Lancashire card-rooms the dust problem is being satisfactorily dealt with, though the coarser varieties of cotton still make considerable trouble. The more free use of humidifiers is effective in bad cases, but operatives do not favour this method, and personally I agree with them. If properly taken in hand, ventilation should do all that is necessary. The methods of cleaning away the dust and fluff deposited on the machines in card and blowing rooms are deserving of attention. I think vacuum cleaners will in the future universally adopted for cleaning cotton machinery, becau they clean without throwing the dust into the air. Cas of asthma among men emptying dirt boxes can be sat factorily prevented by the use of a suitable respirato I have adopted a perforated aluminium and rubber one cover mouth and nose. A strip of surgeon's lint plac inside this, which can be readily changed as desire collects an enormous amount of dust. In gassing rooms t dust and fumes can be kept out of the surrounding a space and conducted outside the building by attaching exhaust duct to each burner or series of burners.

FATIGUE.

In former days the continuous exposure to excessive high temperatures in hermetically sealed spinning roon or to the hot and almost saturated air of the wet weavi sheds, must have produced a definite and lasting impai ment of constitution. The cotton operative generally a much healthier individual to-day. Though the gener improvement has been mainly due to circumstances e plained elsewhere, I cannot ignore the important bearin which the reduction of hours of work must have on t whole subject. Granted the existence of fatigue in particular industry, such a measure is the most direct a probably the most effective means which can be taken bring about its reduction. Unfortunately, we have nothi in this country in the way of comparative statistics to sho the direct effect of this important reform on the cott operative.

The Industrial Fatigue Research Board published 1920 what is apparently meant to be a preliminary treati on individual differences in output to be found in vario processes of the cotton industry and the extent to whi production in each process depends upon human as oppos to mechanical efficiency. In mule-spinning and rin spinning the chief feature was the comparative smallne of the mean variation and the slight differences betwe maximum and minimum values. Here the part played the operative is very minor in comparison to that unde taken by the machine, so that there is little opportunity f the manifestation of individual differences in efficiency. drawing, slubbing, and roving the human factor was mo pronounced than in spinning, and less than in weavin On the whole, the investigations show the extreme difficul of trying to gauge fatigue in the spinning industry output.

When temperatures are excessive—that is, over 90° F.- one does come across spinning-room operatives who sho definite signs of fatigue, mainly, of course, towards t end of the day's work. It would also appear that mul spinners suffer to an abnormal extent from varicose vein varicocele, and flat-foot. In the matter of static fatigu due to prolonged fixation of certain muscles through havin to work in a strained position, the inquiry into bobbin winding showed that any strained position taken up w only temporary, and that the ill effects were quickly rect fied. The lifting and dragging of heavy skips and ti still requires some alteration. Provision should be mad for this work to be done in all cases by men or well grow youths, and the most successful practice is to move t skips from point to point on low bogies running on tran lines. It is also wrong for growing girls to carry eve 27-lb. laps from scutchers to cards. They rarely attem to get into the way of using each shoulder alternately, an are consequently liable to show some degree of later curvature of the spine.

The only systematic investigation of any definite val which the Industrial Fatigue Research Board has so f been able to carry out on the incidence and extent fatigue in the cotton industry is described in the Repo on Variation of Efficiency in Cotton Weaving (1923 Efficiency is shown to depend on two factors—namely, t number of loom stoppages and the ability of the operati to attend to them. Yarn breakages are the princip cause of stoppages, and the more numerous these becom through physical defects in the yarn or adverse atmospher conditions, the greater is the loss in efficiency. The fatig is measured by an ingenious method [described and illu trated by the lecturer] which takes cognizance of t

human as distinct from the mechanical efficiency, and it is shown that the highest efficiency is manifested on Tuesday mornings, after low efficiency Mondays; then there is a progressive decrease during the remaining mornings of the week. The efficiency is much less during the afternoon spells, and steadily diminishes in the afternoons from Monday to Friday. I think it is reasonable to suggest that this daily decrease is due to cumulative fatigue caused by incomplete recovery from daily fatigue, except on Monday mornings, when the low efficiency is due to the process of getting into the stride. The efficiency peak, in hourly variations, is in evidence from 8.15 to 10.15 a.m., and decreases each subsequent hour, except for the hour immediately after the dinner stoppage, but the drop commences sooner in the afternoon than in the morning.

Twister's Cramp.

In the report of the Chief Inspector of Factories for 1919 Dr. Bridge describes a disability among twisters, loomers, or twisters-in, as they are called, whose work it is to join the ends of a new warp to the warp ends of a woven piece. The overworking of a particular set of muscles produces a permanent condition of the hand which either prevents the worker from continuing his employment or precludes him from earning his former wage. The muscles of the left forearm as well as of the thumb and index finger are involved in a complex series of movements. The subjective symptoms are pain, tenderness, weakness, and loss of power. The principal physical sign is an unusual flattening of the thenar eminence of the palm. Bridge believes the cause to be a central nervous lesion, and in addition a local fibromyositis of the thumb muscles. As a considerable amount of this particular work is now done mechanically the disability should tend to disappear.

LIGHTING.

The modern spinning mill is well provided with window space, but owing to the length of the mule the rooms have to be of a width which in many cases prevents direct light reaching the centre. In weaving sheds, universally of one story, roof lights facing north are invariably adopted, but there is sometimes diminution of light from obstructive buildings. Prismatic glass might be an advantage for cotton factory windows. Artificial illumination is mainly provided by electricity. In the Third Report of the Departmental Committee on Lighting (1922) it is shown that there is a very general inadequacy in cotton factories. Weaving processes were found on the whole to be better lighted than spinning processes. Owing to the universal ignoring of the provision for effective shading of lights, glare is a very pronounced factor in all factory lighting systems.

INFECTIONS.

"Shuttle-kissing."

The practice of "shuttle-kissing" has to do with the threading of the shuttle-eye each time a fresh cop is placed in the shuttle. The weaver places the outside of the shuttle-eye to his lips, and with a strong inspiratory effort draws the thread through. This action may be performed by a four-loom weaver four or five hundred times a day, and although each weaver has his own set of shuttles, they may receive an additional kiss from the tenter, tackler, or overlooker. The diseases likely to be caused by this objectionable practice, according to the replies sent by fifty-eight Lancashire medical officers of health to questions circulated by the county medical officer, are syphilis, phthisis, diphtheria, caries of the teeth, skin diseases, septic throat, scarlet fever, and infective conditions of the mouth; but only five specific instances were given of actual transmission of disease, and even in these cases, though every one was carefully investigated, no justification was found for making the shuttle responsible for causation. Though "shuttle-kissing" may not have brought about all the ill of which it is suspected, there is no doubt that it is potentially dangerous to health. The newspaper campaign of 1911 stimulated invention, and a number of devices for shuttle threading without kissing came on the market. The Northrop loom, which has a mechanical shuttle-threading arrangement, causes no trouble during weaving, and supports the view that practical methods are available for doing away with the need for this exceedingly bad habit.

Weaver's Cough.

In certain dry sheds the operatives have had an unusual type of cough and dyspnœa. An investigation by Dr. E. L. Collis, on behalf of the Home Office, showed that the warps used in these instances contained less than the ordinary amount of size, and that the usual antiseptic, zinc chloride, had been omitted. The warps had also not gone through the complete process of drying after sizing, and had developed mildew on being placed in the looms. A reversion to "dry taping" for all the warps cured the disease.

Infected Cotton.

In certain outbreaks of small-pox in the cotton districts in recent years it has been suggested that cotton may have conveyed the infection. The theory is that undetected mild cases exist among the negro cotton-pickers, and that, as all the tufts are handled in the picking, some of them may become infected. Two outbreaks certainly present some prima facie evidence inculpating the cotton. In one outbreak, in which there were eleven cases in one mill, the cases were distributed among the workers in the different processes, suggesting that the infection travelled with the cotton.

SANITARY ACCOMMODATION.

To the best of my knowledge, every Lancashire cotton district is provided with a good high-pressure public water supply, and practically all are served by well designed drains and sewers. Yet the closet accommodation is of a very insanitary type in quite a large number of factories. The water-closet system is the proper one for cotton factories, and in spinning mills accommodation should be provided for each sex on each floor. The absence of a public sewer is no deterrent in these days of the septic tank and filter bed.

Clean, well ventilated cloak-rooms, with hygienic metal lockers, perforated at the top, bottom, and in front, and capable of being sufficiently heated to dry wet clothing, are a necessity for cotton mills. The present practice of changing clothes behind mule creels is objectionable from the hygienic point of view, and, where the two sexes work together, from the moral aspect as well. All Lancashire cotton towns are fairly well provided with public baths. Workers in the spinning and doubling rooms, who necessarily perspire a great deal, have the greatest need to bathe frequently.

MULE-SPINNER'S CANCER.

In cleaning their machines most operatives get exposed parts of the body soiled with lubricating oil. Mule-spinners and piecers have a specially dirty task when cleaning the headlock gears, and also they are subjected twice each day to a definite impregnation of certain parts of their clothing with this material. The cotton trade was first made aware of the fact that mule-spinners were particularly susceptible to a form of skin cancer by an article in the BRITISH MEDICAL JOURNAL (November 18th, 1922) by Southam and Wilson, in which it was stated that out of 141 patients attending the Manchester Infirmary with epithelioma of the scrotum during a period of twenty years, 69 were mule-spinners. In a report published by a Special Committee of the Home Office (1926) [BRITISH MEDICAL JOURNAL, April 24th, 1926, p. 746] it was stated that 539 cases had been traced. The region involved was not invariably the scrotum, as first suggested, for 89 cases had other parts affected. Recent mortality figures show 23.5 per cent. in which the affection was elsewhere than at the scrotum. The growth is usually preceded by a warty formation which may exist for several years before becoming cancerous. When the mule is started the oil comes in contact with the spindles and is thrown off as a fine spray for about two minutes, the spinner getting the full benefit of this spray as he moves backwards from the advancing carriage, the result being that a distinct oily patch is to be seen on his trousers at the level of the pubes.

The remedy for this disease lies either in the provision of innocuous oils (not attainable until the actual carcinogenic

factor is known and a method of removal discovered) or in preventing contamination (a practicable solution). I cannot conceive that engineers famous for their conceptions of the most intricate self-acting motions ever adapted to any mechanical contrivance can be nonplussed by a spindle-bearing. Cleanliness must also be urged, and employers should arrange suitable washing facilities. Whatever is done, however, there must be a body of men already infected from whom a stream of fresh cases will be drawn, and that these should receive prompt treatment is an axiom in dealing with epithelioma. The Home Office Committee, with a view to detection of cases, very properly recommends medical examination every four months for all spinners over 30 years of age.

ACUTE ABDOMINAL EMERGENCIES COMPLICATING PREGNANCY AND THE PUERPERIUM.*

BY

JOHN S. FAIRBAIRN, M.A., B.M., B.CH.OXON.,

OBSTETRIC PHYSICIAN, ST. THOMAS'S HOSPITAL.

THOUGH, owing to the lamented death of Mr. J. E. Adams, I have no surgical partner in opening this discussion, I intend to keep to the part I had agreed to take and to speak only from the standpoint of the obstetrician and gynaecologist. My chief object will be to point out to the surgeons how symptoms arising from pregnancy and its complications may make diagnosis and treatment more difficult in abdominal emergencies.

It would seem to be a reasonable supposition that the liability of women to acute mechanical disturbance of the bowel and to the spread of inflammation in the peritoneum would be greater during child-bearing owing to the increase in, and displacement of, the abdominal contents, followed by their rapid diminution after labour, and gradual return to the non-pregnant state.

Diagnosis is clearly the outstanding problem, because it is materially affected by pregnancy, which may introduce additional symptoms, such as vomiting, abdominal pain and distension, and jaundice. These symptoms are also those which are outstanding ones in acute abdominal emergencies. Further, the pregnant uterus becomes an abdominal tumour after the third month, and in its later stages so large that it interferes with the appreciation of abdominal physical signs.

* The introductory paper to a discussion by the Medical Society of London, February 28th, 1927.

Abdominal symptoms may arise either as part of a disorder of metabolism—the toxaemia of pregnancy—or from mechanical effects or abnormalities of the pregnancy or reproductive tract.

Vomiting.

Severe vomiting is not unusual in pregnancy, and great caution must always be exercised before accepting pregnancy, *per se*, as the explanation of this symptom unless there is definite evidence to that effect. The vomiting of pregnancy usually begins as soon as the patient knows she is pregnant—that is, about the time of the first missed menstruation—and continues and may become aggravated from then onwards over a period of two or three months. It is usually more severe in primigravidae, but tends to recur in subsequent pregnancies in lessening degree. The vomited material is commonly food recently taken and little altered, but later of bile-stained fluid. Coffee-ground vomit is only seen in long-continued and in definitely toxic cases. Constipation almost always accompanies it, but an action of the bowels is generally obtained by enemata. The abdomen is usually sunken and not distended. Vomiting beginning after the fifth month without evidence of toxic origin is unusual and should suggest an organic cause; still more any vomiting that rapidly progresses towards a faecal type.

The cases, therefore, that particularly require investigation as to some cause other than pregnancy are those in which vomiting arises late in pregnancy (and not as a simple aggravation and persistence of the early morning sickness), in which vomiting has not occurred in previous pregnancies, and when there is no evidence of impairment of the renal and hepatic functions on clinical and biochemical examination. In cases of doubt treatment on the ordinary lines, usually by isolation away from home under capable nurses, should be tried for as long as the patient's condition permits, and if successful will settle the diagnosis. If there is definite evidence of renal or hepatic insufficiency, or if no improvement results from treatment, the pregnancy should be terminated. Early in my career I took over a case from a surgical colleague, an acute clinical observer, because he had discovered no other reason than the pregnancy for continued vomiting. The vomiting differed in type from the ordinary vomiting of pregnancy and there was no albuminuria or jaundice. Shortly after the termination of a seven and a half months' pregnancy an urgent operation was performed for obstruction from a carcinoma of the colon that became obvious very soon after the uterus was emptied. Many similar cases of gastro-intestinal disease are recorded in which vomiting was wrongly ascribed to the pregnancy.

JAUNDICE.

Another type of the toxicosis of pregnancy that may cause difficulty in diagnosis is that characterized by jaundice, vomiting, and epigastric pain, suggesting gall stones or cholecystitis. Petersen,[1] in an analysis of 35 cases of gall stones during pregnancy and the puerperium, found jaundice present in 60 per cent. of 25 that occurred during pregnancy, whilst one case only out of 10 arising in the puerperal period had jaundice. Usually, in the toxaemic cases, vomiting is a marked feature and may become coffee-ground in character and albuminuria is usually present. In a case recorded by Banister and Stevens[2] from Queen Charlotte's Hospital as a "*fatal case of acute* haemorrhagic hepatitis following toxaemia of pregnancy" the patient had jaundice with severe epigastric pain and tenderness in the umbilical area and to the right side. The temperature was 100° F. and the pulse rate 100. There was also referred pain in the left shoulder and haematemesis, and the authors of this paper considered these last two features as unlike a case of gall stones.

My colleague Mr. Maybury has kindly given me particulars and allowed me to quote a case of his illustrating the difficulty in differentiating gall stones from the toxic hepatitis of pregnancy.

The patient was aged 26 and about two months advanced in her second pregnancy. There was a history of her having had an attack of jaundice of a few days' duration about five years before; it began with pain in the left scapula, which soon passed off but

was followed by epigastric pain and slight jaundice, and was then ascribed to gall stones. When first seen symptoms similar to those of the earlier attack had been present for a fortnight, the stools were clay-coloured, the liver enlarged and a little tender, but the gall bladder could not be felt. Medical treatment was continued for another fortnight, but the jaundice and epigastric pain persisted with troublesome general pruritus. Exploration of the gall bladder was undertaken, but it was found empty with not a trace of bile in the common duct. Probes and a spoon were passed into the right and left hepatic ducts and a little "mud" removed. A tube was inserted into the common bile duct and a drain to the transverse fissure, and next day bile began to flow both by tube and drain. A fragment of liver tissue, taken for histological examination, showed undilated bile ducts, no fat, and but slight degeneration of the liver cells. Albuminuria and some casts were found in the urine. The blood urea was 30 mg. per 100 c.cm.—that is, slightly above the normal for a pregnant woman—and the van den Bergh and Fouchet tests indicated merely a catarrhal jaundice. The patient became more drowsy and her condition worse; abortion occurred spontaneously a few days after the operation, and fourteen days later the patient died. There was no *post-mortem* examination.

Like other forms of toxic hepatitis, that due to pregnancy may cause difficulty in its differentiation from acute conditions arising in the gall bladder and its ducts, so having mentioned them it may be well to call attention now to the uraemic states which, in pregnancy as apart from it, may give rise to anomalous symptoms of abdominal disorder, particularly vomiting, ileus, and rapid pulse rate.

I may quote a case of this kind admitted for severe vomiting, but of a type unlike the vomiting of pregnancy, as it occurred but once or twice a day and consisted of a large quantity of brown and somewhat offensive fluid. Epigastric pain and distension were present, and the case appeared to be one of acute dilatation of the stomach. The patient was acutely ill; she had slight albuminuria, but a blood urea content of nearly 200 mg. per 100 c.cm. She passed into coma, thus settling the diagnosis, but recovered rapidly after evacuation of the uterus.

Abdominal Pain.

The commoner causes of acute abdominal pain arising from conditions more or less directly connected with pregnancy may be mentioned. Pain severe enough to cause great distress, faintness, and collapse may occur with an intrauterine pregnancy if bleeding takes place into the uterus and the blood is retained there. Its most typical form is seen in concealed accidental haemorrhage, when the sudden onset and collapse produce an abdominal catastrophe of a most striking character. The patient may be about her ordinary duties and be seized in a moment with alarming faintness and agonizing pain. It, however, rarely occurs until the patient is in the later months of pregnancy, when the tender and board-like uterus, together with the cessation of all signs of foetal life and the inability to recognize any foetal parts, make the diagnosis clear. Occasionally, however, similar retained haemorrhage with increased tension in the uterus may arise much earlier in pregnancy, especially in vesicular moles, and suggest an ectopic pregnancy with intraperitoneal bleeding.

The rare cases of spontaneous rupture of the pregnant uterus, usually through the scar of a Caesarean section, are also characterized by severe *abdominal pain, collapse,* and signs of internal haemorrhage, but without evidence of intrauterine tension.

A marked abdominal crisis arises from rupture of, or leakage of blood from, a tubal gestation. These cases, however, differ somewhat from the group comprised in the title of our discussion, because the vast majority of them occur at so early a stage of pregnancy that the question as to whether the woman is pregnant or not must first be decided. Hence the history is all-important in diagnosis. The commonest, and happily the least serious, termination of a tubal gestation is the formation of a tubal mole, and that rarely gives rise to severe symptoms. The pain, however, is sudden in onset and may be accompanied by faintness, vomiting, and some degree of shock, and as it tends to recur may suggest a more serious abdominal cause. The bleeding is not usually severe enough to produce evidence of internal haemorrhage, but the tenderness of the hypochondriac area, together with the history and the uterine bleeding which is its most constant accompaniment, usually makes the diagnosis lie between an intrauterine abortion and a tubal abortion or mole. If seen later, when a tubal or pelvic swelling is recognizable bimanually, the diagnosis may rest between a tubal gestation, a tubal inflammatory swelling, or appendicitis, if on the right side.

The rarer cases of intraperitoneal flooding from a tubal rupture are usually fairly characteristic. The blanching and collapse are immediate and obvious, the abdominal tenderness is widespread, and there may be dullness in the iliac fossae. There can rarely be any hesitation in these cases as to the immediate necessity for abdominal exploration.

Severe abdominal pain may be caused by acute necrobiosis of a uterine fibromyoma, and may sometimes be accompanied by other symptoms sufficiently serious to suggest immediate operation. In a paper[3] of mine on this necrotic change in fibroids (vulgarly termed "red degeneration") two cases are mentioned that were operated on as urgent cases, one by Sir John Bland-Sutton at the Chelsea Hospital for Women, and the other by Mr. Battle at St. Thomas's Hospital, and reference is made to another recorded in medical literature. The disturbance caused by these necrotic tumours, however, rarely reaches a degree that would enable them to be classed as emergencies. The diagnosis depends on the discovery of a nodular enlargement of the uterus tender on palpation.

Strangulation of an ovarian cyst by torsion of its pedicle is particularly liable to occur during pregnancy and lying-in, and is a more frequent cause of urgent symptoms. Most often the symptoms are of a subacute type, but occasionally they are sudden in onset, and so severe as to simulate internal strangulation of bowel, and every now and then cases are admitted to hospital and operated on as emergencies owing to their being considered as possible cases of acute obstruction. Torsion is commoner in medium-sized and small than in large cysts, and those in the abdomen rather than those in the pelvis. Hence a cyst accommodated in the pelvis before pregnancy may later be drawn up into the abdomen with the uterus, and may remain unrecognized until torsion of its pedicle occurs. In pregnancy, and to a less degree during the puerperium, its presence may escape detection till the onset of pain, possibly with vomiting and distension. Owing to the haemorrhage into the cyst wall and increased tension, the cyst is more easily detected by palpation after torsion has occurred, and when recognized apart from the uterus the diagnosis is usually obvious.

Torsion of the pedicle of a pedunculated subperitoneal fibroid is a much rarer event, and I have never met with it. Torsion of a fibroid uterus at the cervix has also been described. A case causing urgent symptoms is described by Connell.[4] Infection of a myoma with local peritonitis is another unusual way in which these tumours may cause urgent symptoms.

Peritonitis, local or general, arising from infected tubes or ovaries is rare during pregnancy, because sterility usually results from inflammatory disease of the uterine appendages. Occasional instances do occur, some of them possibly cases in which one side only is involved or in which a gonococcal infection has been acquired at the same time as the pregnancy. In others the infection is not the usual ascending infection by the mucous tract, but a descending infection from the appendix or elsewhere, or possibly a blood-borne infection of a corpus luteum in the ovary from a septic focus elsewhere in the body. Cases of this kind with double suppurative disease have been recorded by Donald,[5] Elbrecht,[6] and Schmid.[7] The only point here that need be emphasized is that the rare possibility of an acute spread of infection from the uterine appendages is not excluded by the patient being pregnant.

The pyelitis or pyelonephritis of pregnancy is often a puzzling condition which may simulate an acute abdominal emergency, and has been the cause of many an innocent appendix suffering unjustly the extreme penalty of the law. It may arise with suddenness, and is most common on the right side, next bilateral, and least common on the left side. It is associated with tenderness and rigidity over the appendix area, and, as pointed out by Napier Burnett[8] and C. B. Lockwood[9] (in *B. coli* cystitis), with abdominal distension and flatulence. It may begin with a rigor and sudden rise of temperature and pulse rate, usually after the fourth month of gestation and most frequently about the sixth month. It is more common in primigravidae. It may or may not be associated with cystitis. The diagnosis depends largely on the recognition of the pyuria

and bacilluria, usually due to *B. coli*, and the tenderness in the loin and costo-vertebral angle. Similar tenderness in the loin may also be present with a retrocaecal appendix, but the higher degree of fever with a relatively good pulse and general condition helps to distinguish it from appendicitis or other cause of local peritonitis.

Abdominal Distension.

Constipation and flatulence are frequently complained of by pregnant women. Abdominal enlargement is often noticed in early pregnancy before the uterus has become an abdominal organ. Thus women will say that abdominal enlargement, of a degree that has necessitated the loosening of their garments, has been present for some weeks before the uterine fundus is palpable above the pubes. Tympanites or obstinacy of the bowels of a degree sufficient to give rise to acute symptoms, or even to simulate obstruction, is very unusual. There are, however, in the Continental and American medical journals[10 11 12] records of cases of "ileus in pregnancy," which include both instances of intestinal obstruction due to mechanical causes and of intestinal paresis ascribed to the pregnancy itself, either as a mechanical effect or as a toxaemic manifestation.

Stork[13] describes six cases, of which four were due to intussusception of small intestine, to volvulus of mesocolon, to adhesions, and to strangulation by a band, but for the two remaining no cause was discovered apart from pregnancy, and in both the evacuation of the uterus was followed by the passage of flatus and disappearance of the distension. Stork, therefore, advocates laparotomy to discover the cause of obstruction, and, in the event of no other cause being found, that the uterus should also be opened and emptied. Excepting the cases of intussusception and volvulus, the other two mechanical obstructions recorded by Stork had previously had abdominal sections—one for gastric ulcer and the other for ovariotomy. In looking through the literature I have been struck by the fact that a notable proportion of the cases of intestinal obstruction during pregnancy and labour have been previously subjected to abdominal operations. Though it may be rash to generalize from such secondhand impressions, I venture to call attention to this point. Two such cases were recorded at the Section of Obstetrics and Gynaecology of the Royal Society of Medicine as having occurred during labour. In one (Williamson's)[14] there was a large tract of intussuscepted intestine that had passed into the stomach through a gastro-enterostomy wound. In another (Clifford White)[15] a volvulus of the caecum and ascending colon had occurred in the sac of a hernia resulting from an operation for the drainage of an appendix abscess four years previously. It certainly would not be surprising if the changes in the abdominal contents that are associated with pregnancy and labour should be specially liable to produce intestinal obstruction in patients with adhesions, operative herniae, and other conditions of the kind.

The only case of ileus during pregnancy I have had in my own practice[16] was in a woman with an extrauterine abdominal pregnancy, unrecognized as in any way abnormal till she was about eight months pregnant, when severe vomiting led to her admission to hospital. I saw her because the question of operation for intestinal obstruction had become urgent, and in making a pelvic examination found the foetus outside the uterus. The removal of the foetus and extrauterine sac relieved the obstruction. It may be as well to draw attention to the analysis of 100 cases of advanced extrauterine pregnancy by Gordon Ley,[17] in which attention is drawn to the pregnancy being apparently normal in one-third of the cases. This means that such symptoms as arose in the case just quoted may occur without the abnormal situation of the pregnancy being suspected.

The period in pregnancy in which mechanical trouble from it is likely to arise is after the uterus has become abdominal in position, when displacement of the intestinal contents is most marked. Labour, with its marked change in the intra-abdominal pressure and content, is a time when disturbance is most to be expected. Urgent symptoms of such disturbance may arise then or a few days later.

The puerperium is, in addition, a time when the effects of septic infection during labour become obvious, and rightly the mind of the attendant turns to infection fr the genital tract as by far the most probable explanatic Though this is a fair assumption, the ordinary rule practice must hold good, and that is, to operate in a case in which there is a possibility of the presence of a acute intra-abdominal condition that may be relieved operation, whether arising from the genital tract elsewhere.

Appendicitis.

So far I have based my remarks chiefly on the sympto that may arise out of the pregnancy and make accur diagnosis difficult; I will now take one or two of the mc common abdominal emergencies as examples, and will beg with appendicitis as being the commonest, and one which we must all have seen a few cases during pregnan and labour. Appendicitis in relation to obstetrics a gynaecology was fully discussed by Fraenkel[18] in 1898, b I will chiefly depend on a recent and very useful artic by Jerlov[19] on 456 cases collected from the maternity a general hospitals of Sweden over twenty years. Two-thir of the women were under 30, and nearly half were in the first pregnancy. Jerlov considers that pregnancy has tendency to increase the incidence of appendicitis, for t proportion of cases was no greater than in the corr sponding non-pregnant Swedish population. On the oth hand, appendicitis in later pregnancy is more serio because of the greater liability to the upper part of t abdomen being affected, and the lessened chance of p gravitating towards the pelvis. Also abortion and labo tend to a spread of the infection. An incorrect or la diagnosis was frequently made owing to symptoms bei ascribed to some disorder of the pregnancy and, in t later months of pregnancy, the abdominal pain was som times taken for the pains of labour. He lays some stre on painful foetal movements as of diagnostic value, a notes that in many severe cases the temperature w unusually low and the pulse rate disproportionately raise He discusses the differential diagnosis from pyelitis, acu salpingitis, tubal gestation, twisted ovarian cyst, a cholecystitis. Inflammation about the gall bladder particularly liable to be confused with appendicitis the later months of pregnancy, when the appendix occupi a higher position in the abdomen.

Other observers also have emphasized the danger of t spread of infection in cases which arise during labo or in which premature labour is started by an attac Warnings are frequently issued against such manipulatio as the expression of the placenta for fear of causing sprea

Treatment.

Once the diagnosis is made, the obvious rule is that t treatment should be the same as it would be if there we no pregnancy, save that the presence of a pregnanc weights the scales against expectant treatment. Jerlov, fact, urges that in slight or suspicious cases of appendicit the pregnancy should be regarded as an influence in favou of operation rather than against, because pregnancy do not affect the mortality in the mild cases, whereas in t severe and in all those with local exudation the outlook made more serious. Petersen[1] says much the same regard to gall-bladder infections. When the diagnosis uncertain it is also safer to perform an exploratory lapar tomy than to interfere with a normal pregnancy in t hope that accurate diagnosis will then be possible.

Interference with a pregnancy is justifiable only if som operative procedure is contemplated which the pregnan uterus would make more difficult of performance. As rule, too, the really acute cases would rarely permit this being done. The type of case in which it would worth while first to terminate the pregnancy would be, say a carcinoma of the bowel causing obstruction and yet in a operable stage. In such a case, recently under my car I induced abortion at the sixth month after consultatio with a surgical colleague, though it was difficult to deter mine whether a radical operation was possible or not. Th woman had to be operated on urgently because of th development of acute obstructive symptoms a few day after the emptying of the uterus, when it was found tha colotomy was the only possible procedure. Except in suc subacute cases it is impossible to empty the uterus sav

by Caesarean section at the same time as the main operation is done. In infective cases hysterectomy would be substituted because of the risk of infection of the puerperal uterus and general septicaemia, and thus would add materially to the time taken in the operation and to the shock entailed.

Generally speaking, the rule should be that the minimum operative procedure that will meet the needs of the case, and the one that can be performed in the shortest time, should, so far as possible, be selected. There should be as little disturbance of the uterus as possible.

In addition to reasons already given, the prognosis in pregnant women is rendered graver by the possibility of abortion or premature labour following the acute abdominal condition or the operation done for its relief. Abortion or premature labour is liable to result in a generalized infection in septic cases or cases with a septic focus. Manipulations for retained placenta or other procedures involving pressure on the abdomen also add to the risk of spread of infection.

THE THYROID AND MANGANESE TREATMENT IN ACUTE PNEUMONIA.

BY

NELSON J. ROCHE, O.B.E., M.R.C.S., L.R.C.P.,

SOUTHSEA, HANTS.

HAVING been much interested in the account given by Dr. H. W. Nott[1] of his treatment for acute pneumonia by rectal injections of a solution of potassium permanganate, I decided to try it when occasion arose.

An outbreak of measles in Southsea during the end of last summer allowed me to test the method sooner than I expected, and with such satisfactory results that the following notes of five cases will, I think, be read with interest.

CASE I.

A girl, aged 5½ years, had been ill with measles five days when first seen; the rash was vivid on the trunk and legs but was fading on the face and arms. The respirations were rapid and shallow, cough was severe, the lips were blue, and the complexion cyanosed; the temperature was 103°. Well developed signs of

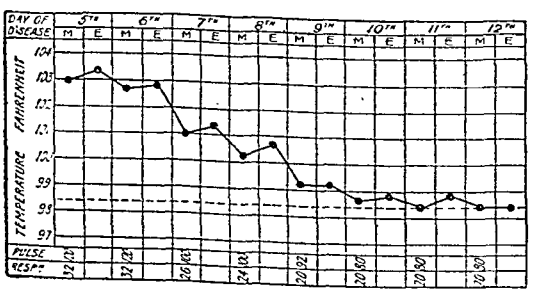

FIG. 1.—Case I.

bronchopneumonia were found in both lungs. A fresh solution of potassium permanganate was prepared of the strength of two grains to one and a half pints of hot water, and three ounces were injected three times during the ensuing twelve hours. Sixteen hours after the first injection was given I found the child decidedly relieved. Her colour was better. I was told she had been quieter during the night, having slept uninterruptedly for two hours. After similar injections had been given every four hours throughout the next twenty-four hours I found her greatly improved. She had had six hours of continuous sleep during the night, cough was less frequent, easier and loose, and her expression and complexion were better. The respiration and pulse rates had slowed considerably, whilst her temperature was falling satisfactorily. Injections were continued at six-hourly intervals for three days more and every twelve hours for another four days, when they were stopped. Convalescence was rapid and uneventful. (See Fig. 1.)

CASE II.

An infant, aged 15 months, was in its seventh day of measles. Both lungs were affected with bronchopneumonia, more marked on the left side. The general condition was serious, as the child, worn down by a week's illness and considerable diarrhoea during the previous twenty-four hours, was restless, refusing feeds, and markedly cyanosed; the temperature was 103.4°. After washing out the rectum with sterile hot water, injections of two ounces of the solution were given three times in twelve hours. The harsh

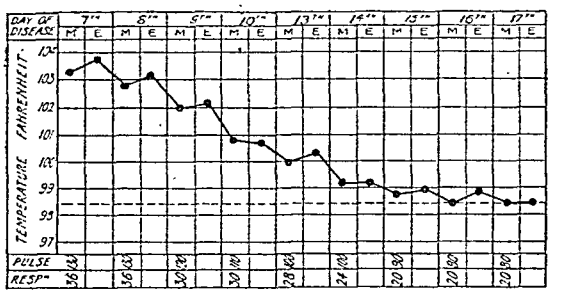

FIG. 2.—Case II.

and incessant cough became easier when the third injection had been given and there was an improvement in the child's appearance. During the next three days injections of the same quantity were given every four hours. Rapid improvement took place, the restlessness, cough, and temperature all lessened, and feeds were taken willingly. Injections were now reduced to two a day for a few days longer, and convalescence was rapid with no complications other than the retention of a little urine, which was easily relieved by seating the child in a basin of hot water. (See Fig. 2.)

CASE III.

A girl, aged 4 years, was seen on the sixth day of measles. Both lungs were extensively affected with bronchopneumonia, and owing to the extreme cyanosis and her general low condition it was impossible not to give a very bad prognosis. Permanganate injections were administered at once, three ounces being ordered every four hours. The following day her condition was much the same, though the cyanosis was not quite so marked. Injections were now ordered to be given at three-hourly intervals, and

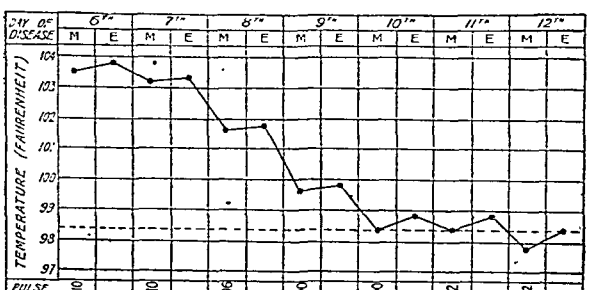

FIG. 3.—Case III.

sixteen hours later—at 4 o'clock in the morning—the child was reported "to have taken a change." Seeing her at 9 a.m. I found the change remarkable indeed. In place of the almost violet-coloured complexion her face was a rosy pink colour, the cough was easy, the expectoration was being raised, whilst her temperature, pulse, and respirations were all declining rapidly. Further treatment was carried on in the manner described in the first two cases; improvement quickly took place and convalescence was again rapid and uneventful. (See Fig. 3.)

CASE IV.

A boy, aged 7 years—brother to the preceding case—was found with a measles rash during my first visit to his sister. He looked ill, and fine crepitations were to be heard at the bases of both lungs. Four-ounce injections were ordered every four hours. Eighteen hours later the condition was unaltered, but twelve hours later still he broke out into profuse perspiration and his

temperature dropped suddenly to nearly normal. A few hours later I found him quite happy and playing with his toys. His convalescence was also uneventful. (See Fig. 4.)

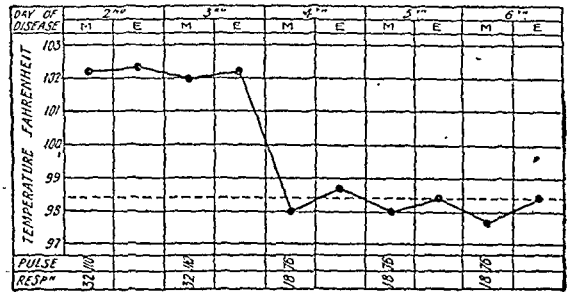

FIG. 4.—Case IV.

CASE V.

A youth, aged 17, very well developed and engaged as an errand boy, was taken ill in the evening with a rigor and with pain in the right side of his chest. Examined thirty-six hours after the onset he showed well marked signs of acute lobar pneumonia, with dullness, crepitations, and rusty sputum. Injections of four ounces of permanganate solution were given at four-hourly intervals for twenty-four hours. As these were easily retained the dose was doubled throughout the following twenty-four hours. Forty-eight hours after beginning treatment I found a remarkable change in his condition. His look of distress had changed to an expression of content. He no longer complained of pain. His respiration rate had dropped from 28 to 18, his pulse from 110 to 93, whilst his temperature had fallen from 103.5° to 101.8°. His cough was less troublesome, and he was able to lift profuse expectoration with comfort and ease, which rapidly lost its rusty colour. He made a quick and uninterrupted recovery, and with the exception of doses of compound ipecacuanha powder in combination with aspirin, in the early stages, he had no other drug treatment throughout his illness. (See Fig. 5.)

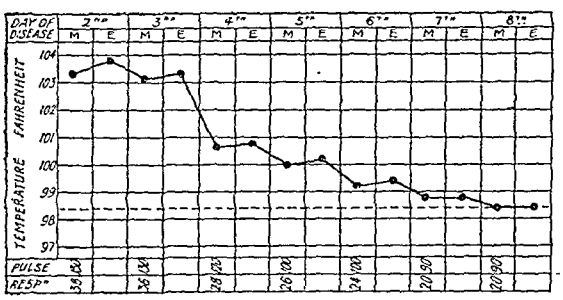

FIG. 5.—Case V.

Although it may be unusual to report so small a number of cases in support of a new line of treatment, the circumstances surrounding these cases seem to make it desirable to do so. I undertook the treatment with some misgiving, but, to my surprise, case after case confirmed what the co-workers at the Ellesmere Port Cottage Hospital had seen, and the temperature charts in my cases seem to follow closely those which illustrated Dr. Nott's paper.

As most practitioners have experienced a disappointment caused by the failure of this or that treatment for pneumonia, it was pleasing to me to find a remedy doing exactly what it had been described it would do; the value of this set of cases is enhanced by the fact that my patients were all treated in their own homes, with ordinary home nursing, with no other medicine, in the case of the children, than a light diaphoretic mixture.

The ease and certainty with which these rapid results were brought about has determined me not in future to allow a human being, and for that matter any animal I cared for, to perish from the toxaemias of pneumonia without attempting to help them by this method.

Believing, too, that we are likely to learn more as to the limitations of this treatment from numbers of short reports coming from general practitioners, working under different conditions, than from a long report drawn up under institutional conditions, I present this for what it is worth; if it should be the first I hope it will soon be followed by others, for by this means we may hear how other complications (otorrhoea, empyema, and meningitis) dependent upon the pneumococcus fare under the permanganate treatment.

THE EARLY TREATMENT OF POLIOMYELITIS.

BY

VERA C. VEITCH, M.B., CH.B.,

CRIPPLES AID SOCIETY'S ORTHOPAEDIC HOSPITAL, HARTSHILL, NORTH STAFFORDSHIRE.

POLIOMYELITIS is an endemic disease which occurs in this country periodically in epidemic form. Its importance justified a discussion at the International Congress in 1913 which was opened by the late Dr. F. E. Batten, whose teaching at the Hospital for Sick Children, Great Ormond Street, in 1912 and 1913 is the accepted doctrine to-day.

In 1921 there was a discussion on the early diagnosis and treatment of acute poliomyelitis at the annual meeting of the British Medical Association (JOURNAL, 1921, vol. ii, p. 225). The discussion was opened by Dr. Farquhar Buzzard, who said that at necropsies which he had attended the cord and membranes in the affected areas had been found to be intensely inflamed and congested. I mention this because it has an important bearing on treatment. In the course of the discussion it was stated that there was no specific drug in the treatment of the disease, and that electrotherapy was harmful in the acute stage, being of use later only as an adjunct to orthopaedic treatment. Treatment on general principles during the febrile stage was advocated, particular attention being paid to warmth and quiet. When the febrile condition had subsided splinting was advised to prevent contractural deformities, to be followed by massage, remedial exercises, and electrotherapy. Where the recovery was incomplete various surgical procedures, such as stabilization of joints and transplantation of tendons, were advocated.

It will be remembered that in 1922 Sir Robert Jones gave an authoritative address on the treatment of paralysis in children to the Section of Diseases of Children of the Royal Society of Medicine (BRITISH MEDICAL JOURNAL, 1922, vol. i, p. 705). My present purpose is to deal only with the early treatment of the disease.

Some three years ago the first early case of poliomyelitis was admitted to the Hartshill Orthopaedic Hospital for treatment. Up to July of last year eight early cases had been referred. Since July, 1926, fourteen early cases have been treated here, all on the same lines, and the results are good.

During the last six years I have seen several hundreds of practically untreated patients who have attended this hospital with deformities of the most disabling type, yet presenting the same initial history as the early cases. On comparing the end-results the conclusion reached is that *co-operation between the physician and the orthopaedic* surgeon is essential from the very onset of the disease. By this means alone will the prevention of most of the deformities in each case be achieved.

The first indication for treatment in an early case of poliomyelitis is immobilization of the inflamed part. This can best be done by fixing the patient on a Thomas's straight frame with head-piece, thereby immobilizing the head and spine. This may seem a drastic measure, but the results, as detailed in my notes of the cases, justify the procedure. Fixation on a frame is our routine method of treatment in all early cases, even if the initial paralysis or paresis is slight. Pain is often a very distressing symptom in the early stages, and has been regarded as intractable. Our experience is that pain rapidly subsides as soon as the patient is immobilized on a frame.

The second indication for treatment is the prevention of contractural deformities. These are caused by unequal muscle balance, and are prevented by fixing the paralysed muscles in relaxation, the fixation being maintained until they are sufficiently recovered to hold their own against their antagonists. The Thomas frame is an ideal splint for fixing the head, trunk, and lower limbs in the position of selection. It leaves the arms and feet to be dealt with if necessary. This is done by moulding a plaster-of-Paris splint to the affected part, and fixing it to the metalwork of the frame. The patient is kept immobilized on the frame until the inflammatory condition of the cord has subsided and the amount of damage to the musculature can be ascertained. The frame is then gradually discarded, and

the paretic or paralysed limbs splinted in the position of selection. We have found that this can be commenced in approximately four to six weeks from the onset, and the frame finally discarded in a further two to three months.

Notes of six early cases treated on these lines are appended.

Case 1.—A boy, aged 3½ years, was first seen three days after onset. He had complete paralysis of both legs, but was able to contract the flexors of the hips slightly with assistance. Back weak. High temperature. Cerebral cry. He was immobilized on a frame, with club-foot shoes holding the feet. Two days later removal of the frame was suggested as the child was thought to be dying, but it was retained, and the acute stage subsided two days later. The frame was discarded in two months. Three months later the boy began to walk, and two years later was leading a normal life.

Case 2.—A boy, aged 3 years, was first seen five days after onset. There was complete paralysis of both legs, thighs, and glutei, and very marked weakness of the back and the abdominal muscles. He was immobilized on a frame with two light plaster cases holding the legs in the desired position. He began to discard splints eight weeks later, and four months after the onset all muscles were acting voluntarily. Back and abdomen good.

Case 3.—A boy, aged 5½ years, was first seen five days after onset with the left leg and foot flail-like. The right leg quadriceps and glutei were normal, but the back and abdomen were weak. He was immobilized on a frame, with a plaster case for the left leg. He first began to discard splints five weeks later, and eighteen months from onset had regained full control of the limbs and was leading a normal life.

Case 4.—A boy, aged 5 years, was first seen four days after onset; the left leg was flail-like, the right quadriceps weak, the back and abdomen very weak, and the left arm weak. He had a high temperature, with periods of unconsciousness. He was immobilized on a frame, with plaster casing of the left leg and arm. He first began to discard splints three months later, and two years afterwards was walking with calliper splint, his arm being apparently normal.

Case 5.—A girl, aged 8 years, was first seen seven days after onset with complete paralysis of the right leg and shoulder. She began to discard splints six weeks later, and two and a half years afterwards had full control of the leg and shoulder, but the grip of the right hand was slightly weaker than that of the left.

Case 6.—A girl, aged 6½ years, was first seen eight days after onset. The left leg and right arm were flail-like, and the right leg weak. The temperature was 100° to 101°, and she was very irritable. She was immobilized on a frame with plaster cases on both legs, and her arm was tied to the top of the splint. One week after fixation the temperature and irritability were much diminished. She first discarded splints six weeks later, and a year afterwards was an apparently normal child.

Of the fourteen cases since July, 1926, in nine both lower limbs, the back, and abdominal muscles were affected. Of these, six are now gradually discarding their splints. In three cases one leg was affected; of these, two are now walking in callipers, and one is free of all splints. In the two remaining cases both upper arms and shoulder girdles were affected. These two children are wearing plaster cases, which are being discarded while in the prone position.

I am indebted to Dr. Mitchell Smith, under whose care these patients were, for permission to publish these notes.

THE ELECTRICAL TREATMENT OF THE PARALYSIS OF POLIOMYELITIS.

BY

R. J. MORRIS, C.B.E., M.D.DURH., M.R.C.P.LOND.,

HARROGATE.

In a paper published in the *Archives d'Electricite Médicale* in February, 1912, Professor Bergonié appealed against the discouraging prognosis given of infantile paralysis in spite of the efforts made by medical electricians to show that this need not be so, and that it is only so when, through lack of courage or through scepticism, treatment is omitted or given as a matter of form, or is badly applied by incompetent persons, or is insufficient as regards intensity, duration, or instrumentation. Electrotherapeutic treatment, more than other methods, requires clinical experience and practical knowledge which it is impossible to acquire through books; and this applies very particularly in cases of infantile paralysis. The part of the medical electrician will begin at the end of the acute stage by making a precise and complete electrodiagnosis as a basis for everything which shall be done afterwards. To examine the leg, for example, a compress soaked in warm weak saline solution is wrapped around the foot and ankle, and a flexible metallic electrode bandaged to it; the patient may be seated or recline on a similar electrode of large size placed about the buttocks. These electrodes are then connected to the poles of a source of faradic current of low tension (coil with coarse winding); this current is passed through a metronome which rhythmically interrupts and reverses it about forty times a second. The intensity of the current is regulated by a progressive rheostat; if the intensity is very gradually increased, the coil being of the proper coarse winding, and the electrodes large, the process will be painless. It is possible to see and feel the muscles which respond, and those which have lost their faradic excitability. To ascertain which muscles show signs of degeneration it is only necessary to move the commutator of the apparatus and send the galvanic current by the same electrodes to be rhythmically interrupted and reversed by the same metronome at the rate of twice a second. By this means the muscles can be divided into two classes: (1) those which have preserved their faradic excitability; (2) those which have lost it and show the slow contraction of degeneration. Having completed the electrodiagnosis the treatment can be continued with the same apparatus.

It will be necessary to commence with the galvanic current rhythmically interrupted and reversed and to follow with the faradic current; the instrumentation is simple, and consists of a source of supply of galvanic current (24 to 36 volts), a metronome to interrupt and reverse the current rhythmically, and a finely graduated rheostat; the milliamperemeter may be dispensed with. This electrization of all the muscles of the limb has the advantage that by sight and touch we can be certain that the affected muscles are well acted on, and we can see the progress and modify the technique. There is no objection to this electrization *en masse* on the theory that the healthy antagonists should not be stimulated at the same time as the partially paralysed muscles. The results are more favourable than in cases subjected to local electrization. The duration and intensity of the electrization are very important. It has been proved by experience and numerous observations carried on over a long period that the condition of the patient improved more and more as the treatment was increased in duration and intensity; it can therefore be laid down as a principle that the intensive treatment of the paralysis of infantile paralysis can be repeated with a duration and intensity not formerly used. Bergonié states that he was driven to this conclusion little by little by ever better results. He quotes, from a large number of cases similarly treated, one of infantile paralysis of the hemiplegic kind. After two months the muscles of the leg responded to faradic stimulation, while in the arms, on the contrary, the biceps, triceps, and deltoid muscles did not respond. Treatment was commenced with an electrode of 300 sq. cm. at the level of the shoulder, and the hand was enveloped in the other electrode. Electrization commenced with half an hour a day at one sitting, then three-quarters of an hour, then one and a quarter hours, always at a sitting, finally one and a half hours at two sittings, then two hours—one hour in the morning and one in the evening; this was continued for two months. The child played and slept during the electrizations; his arm, roused by extensive rhythmic movements, did not make him suffer at all; he did not even wake when the current was intensified. The muscles made such progress that the biceps alone was a little backward, but it contracted at will.

The practice of long electrizations *en masse* by galvanic currents rhythmically interrupted and reversed automatically is the best treatment in these cases. Bergonié frequently stated that, from his experience of over twenty-five years, even in the most serious cases of infantile paralysis a good prognosis can be given if the electrical treatment is intensive, well regulated, and assisted by the adjuvant treatments—muscular relaxation, massage, passive and resistance movements, exercises, and, in particular, warmth to the limbs, as discussed by him at the Congress of Physiotherapeutics in 1910.

FULMINATING MYELOGENOUS LEUKAEMIA.

BY

A. A. HENDERSON, M.R.C.S., L.R.C.P.,

LONDON.

THE case here reported is remarkable chiefly for the uncommon commencement and history of such a case, and also on account of the extreme rapidity of its progress.

The patient was a young man of 28, who had previously enjoyed quite average health with no particular history except of influenza (which his wife and child also had) at Easter. When I saw him on June 11th he said that his friends told him he spoke so softly that they could hardly hear him, while it seemed to him that he was speaking loudly. At the same time he had found on testing that he was "rather" deaf. I found that he was almost equally deaf on both sides and could only hear my watch, which has a loud tick, two inches away. He could, however, hear on the telephone fairly well. He had some wax in the right ear, but the hearing was no better after its removal. The tonsils were large and flabby but not inflamed, and the pharynx was granular. He complained of having catarrh in the nasopharynx, but said that otherwise he felt as fit as ever. I prescribed nasal douching, and saw him again on June 16th. His hearing was the same, and he still said he was quite as fit as usual but annoyed at the deafness. As he thought he was a little better I told him to continue the douching and return in a week. On June 23rd he was rather more deaf but felt the same. I arranged then for him to see Mr. F. J. Cleminson, who told me that the whole of the lymphoid tissue of the nasopharynx was in a state of hyperplasia, that the deafness was mechanical, due to the blocking of the Eustachian tubes by this, and that vigorous local treatment was indicated. He asked me to see if any lymphatic glands elsewhere were swollen, as he suspected lymphadenoma or some general lymphatic condition.

I examined the patient on June 24th, but beyond a small gland in the left axilla could find nothing abnormal. The spleen was not palpable. I visited him on June 27th; he was thoroughly annoyed at being kept at home doing the nasal drill, etc., "as he felt so well." On June 30th he had a swollen submaxillary gland and the gums looked a little red. That evening for the first time his temperature was raised (99.6°). On July 1st the gums were more swollen and looked a little bluish, the submaxillary glands were larger, and he had some swelling beneath his tongue. The temperature was normal in the morning and 101° at night. On July 2nd the gums began to bleed and he also had some haematuria, and the temperature rose to 102.4° at night. I had ordered him arsenic that morning, and he had kept to his bed since the morning of July 1st, which was the first time he began to feel that he was "not well."

On July 3rd his condition was similar but he was weaker. The spleen was just palpable. A blood count showed 5,250,000 red cells and 200,000 whites; one-eleventh of these were polymorphs and there were numerous myelocytes. The condition now became rapidly worse. His deafness increased, he became pale and more swollen in the face, and the evening temperature was generally above 102°. On July 5th the spleen was two fingerbreadths below the costal margin. On this day he began to take capsules of benzol. The gums ceased to bleed on July 7th and the haematuria also stopped. The mouth was intensely uncomfortable; he rinsed it frequently day and night, but was unable to sleep for more than ten minutes at a time, chiefly on this account. He lost ground generally each day. A blood count on July 12th showed 1,900,000 red cells, 206,000 whites, 30 per cent. haemoglobin. Of the white cells 94 per cent. were myelocytes, 1 per cent. lymphocytes. On July 13th he was in a critical condition, but because his brother was arriving from America strenuous efforts were made to keep him alive with strychnine, camphor and ether, digitalis, and oxygen. He was delirious most of the day and died late that night. His spleen was never more than four fingerbreadths below the costal margin. The glands of his neck became larger each day. He certainly had the look more of a lymphatic leukaemia than a spleno-medullary. The two counts were done by different pathologists.

The only mouthwash which relieved him at all, among several which were tried, was carbolic and liquor potassae. He died thirty-four days after he was first seen, twenty days after he was last at business feeling quite fit, thirteen days after first going to bed—that is, after he first began to feel ill. I am much impressed by Mr. Cleminson's suspicions, which turned out to be quite near the mark, though at that time there was little enough to go on. I have not been able to hear of a similar commencement of this disease or a more rapid termination.

A METHOD OF FIXING HOOKS TO ADHESIVE STRAPPING.

BY

R. E. KELLY, C.B., M.D., F.R.C.S.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LIVERPOOL; SENIOR SURGEON, LIVERPOOL ROYAL INFIRMARY.

ALEXIS CARREL, in his book on the treatment of infected wounds, described a method of closure of a granulating wound by elastic traction. To the edge of a piece of adhesive strapping he fastened a series of shoe hooks by the instrument commonly used by shoemakers. Around these hooks he passed in a criss-cross fashion an elastic ligature. When this was pulled tight the edges of the wound approximated. The great advantage of this method

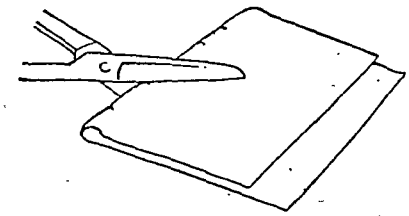

FIG. 1.

over the usual "strapping" of a wound is that the adhesive material need not be removed each time the wound is dressed. The only disadvantage is that the shoemaker's hooks and the instrument for inserting them are rarely available.

Recently I have been using the hooks of the domestic hook-and-eye variety. To sew the hooks on to adhesive strapping is a laborious and annoying business, but by the method here figured any number of hooks may be firmly fastened in a few moments.

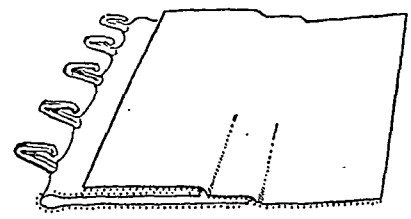

FIG. 2.

A strip of strapping is folded longitudinally but not quite in the middle line, leaving the sticky side out. A tiny nick with the scissors is made in the fold, but only just large enough to allow the hook, but not the flattened circles, to be pulled through. A second piece of strapping is placed over the first, as in Fig. 2, sticky side downwards. The dotted lines indicate the adhesive sides in both pieces of strapping.

When enough hooks have been inserted, the armed strapping is fixed to the skin parallel with, and about

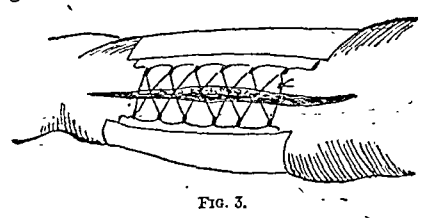

FIG. 3.

one and a half inches from, the edges of the wound. The hooks are then laced, as in Fig. 3. It is not necessary to use an elastic ligature. A piece of silk serves admirably, and slides smoothly through the hooks.

It is possible that this handy method may have been described before, but I have not come across it in surgical literature.

DIAPHRAGMATIC HERNIA IN A WOMAN.

DIAPHRAGMATIC hernia is sufficiently rare to make it an object of interest, and when it occurs in its rarest form, through the oesophageal opening, it is worthy of report.

The condition was found in a well nourished female body, aged 53 years, examined in the dissecting rooms of Belfast University, and no clinical history could be obtained. The stomach lay in a hernial sac of peritoneum, which communicated freely with the general peritoneal cavity through the diaphragm by a hiatus which measured 6 cm. in diameter. Surrounding the peritoneal sac was a distinct layer of what appeared to be thin fascia, which was continuous with the margins of the opening in the diaphragm. The posterior wall of the pericardium lay in front of the hernial protrusion, and the descending thoracic aorta and the bodies of the ninth to the twelfth thoracic vertebrae (inclusive) behind it. Above the level of the stomach the oesophagus showed a well marked curve to the right side, and at the level of the seventh thoracic vertebra it bent suddenly across to the left of the middle line, where it turned sharply downwards to open by a constricted cardiac opening into the stomach. In the transverse part of its course the oesophagus was markedly dilated.

In Boursier's work on herniae only three cases of this form of hernia are quoted; in a series of thirty-four cases of diaphragmatic herniae reported by Sir Arthur Keith in the BRITISH MEDICAL JOURNAL in 1910 there is only one through the oesophageal opening.

Department of Anatomy, Queen's University, Belfast.

UTERINE MYOMA COMPLICATING PREGNANCY.

I WAS interested to read (*Epitome*, November 20th, 1926, para. 485) of P. Firket's two cases of uterine myoma complicating pregnancy, which tolerated intervention. The two following cases, which recently came under my care, may prove of equal interest, especially as one of them closely resembles Firket's first case.

CASE I.

A primipara, aged 30, stated that she usually menstruated for two days only and lost very little blood; menstruation was usually accompanied by slight pain. She last menstruated on May 7th, 1926, and lost the usual quantity of blood. She remained in good health until September, when she began to complain of pain in the left side of her abdomen low down; her temperature was then slightly elevated. A tender lump was felt at the left side, and the uterus was found to be pushed over to the right side. The "tumour" was freely movable away from the uterus. When I first saw her, on September 29th, there had been retching, but no vomiting, the evening before; she had lost no blood per vaginam and had no vaginal discharge. Her doctor told me that the swelling appeared to have got larger within a week, and that he had examined her early in pregnancy without finding any tumour. The fundus of the uterus was a little above the level of the umbilicus, although the menstrual history showed that pregnancy had only lasted four and a half months. No foetal movements were felt and no foetal heart sounds heard.

The patient was admitted to the private block at the Colony Hospital the same day for operation. It was found that the relative positions of uterus and tumour varied from time to time, such variation coinciding with attacks of pain and increased tenderness. The tumour also appeared to vary in consistence. Operating on October 2nd I removed a fair-sized subserous fibroid growing from the left antero-lateral aspect of the uterus. The fibroid was attached by a broad base, and was shelled out fairly easily. There was another small flat fibroid, about the size of a shilling, which I left alone. The patient stood the operation well, and left hospital within a fortnight. She is now having a normal pregnancy.

CASE II.

A 5-para black woman, aged 38, at full term, was admitted to the maternity ward on October 14th, 1926, with a history of a foot having come down following the discharge of waters. The district nurse was alleged to have "put the foot back." The patient had recently been badly beaten by her husband. On admission the temperature was 100° F. and the pulse 90, and there was a foul smelling vaginal discharge. As the patient had no pains, though the discharge and temperature persisted, and there was one rigor, I examined her under chloroform, and diagnosed provisionally a twin pregnancy, though I could hear no foetal heart sounds. The patient was very large, and two swellings, like foetal heads, could be felt. I found the cervix dilated sufficiently to admit three fingers, and I pulled down two macerated legs. I attempted to empty the uterus, but found it quite impossible to get my hand in. Two hours later Nature delivered the body by decapitation; I gave pituitrin, and awaited results. Early next morning the head was delivered in a foul state of maceration. I examined again under chloroform, and with the utmost difficulty the placenta was removed. It was then found that what had been taken to be a second child was in reality a large fibroid. The patient died that night of shock and septicaemia. Laparotomy was from the start absolutely contraindicated.

At the necropsy I found no evidence of internal injury. A very large fibroid occupied the entire left wall of the uterus, the fibrous tissue element greatly preponderating. The tumour was the size of a full-time pregnant uterus; hence my inability to get my hand into the uterus. Neither the patient nor her relatives gave any history of an abdominal tumour previous to pregnancy, and it must be concluded that the fibroid increased in size enormously during pregnancy. On the surface of the fibroid were areas of necrosis, possibly due to pressure.

The following points appear noteworthy.

1. The rapidity of growth of a fibroid during pregnancy, even in a case where the potentialities of pregnancy have been reasonably fulfilled (as in Case II, a 5-para). The palpable presence of a tumour in early pregnancy was excluded in each case.

2. The pressure symptoms which can arise: in Case I temperature, retching, and abdominal pains, simulating an early acute abdomen; and the *post-mortem* appearance of the fibroid in Case II.

3. The difficulty at labour and tragic result in Case II, as compared with the excellent result in Case I.

Conclusion.

It is safest and best in cases of uterine myoma complicating pregnancy to perform myomectomy at least, and, if necessary, hysterectomy. In the case of multiparae the second appears to be the operation of choice, as I feel certain that Case I will later have to undergo it. This conclusion, being based on only two cases, is not, of course, of great weight.

I shall be glad to hear what is the correct treatment in such cases, having regard to popular conservatism in obstetrics, to which I also plead guilty. This subject is of special interest to those practising in the tropics, where fibroids, like keloids, flourish and abound.

Grenada, B.W.I. V. L. FERGUSON.

STRANGULATED HERNIA IN A PSEUDO-HERMAPHRODITE: OPERATION: RECOVERY.

CASES like that reported below are so rare that no apology is necessary for placing it on record.

An infant, 1 month old, had been well until three days before admission to the Booth Hall Infirmary, Manchester. He had then become fretful and had not taken the breast well. Thirty-six hours later he began to vomit; the vomit was not related to food, and just before admission it was brownish; he was not constipated, but the stools had become progressively smaller, the last consisting of only a little slime.

The infant was born at full term but was very small (4 lb.) and in poor condition. He was a pseudo-hermaphrodite; the scrotum was bipartite, each half resembling a swollen labium majus; a deep dimple in the perineum simulated the vagina, and the penis looked like a hypertrophied clitoris. The abdomen was rigid; on each side there was an inguinal hernia and hydrocele. The right hernia was readily reducible. The left hernia was irreducible; the region was hot and tense. The diagnosis was strangulated inguinal hernia.

Operation.—The anaesthetic used was ether (Pinson's bomb). Owing to the condition of the infant it was imperative that as little as possible should be done. I made an incision 1½ inches long over the inguinal canal. The hydrocele, which had surprisingly thick walls, was aspirated. The sac was opened and the neck incised. The condition was found to be a Richter's hernia of the small intestine. The cord and testis were normal, the latter being well down in the scrotum. The gut was viable, and was returned to the abdominal cavity, the neck of the sac was ligated and the external wound closed. A light gauze dressing and strapping were applied.

The infant was given saline with glucose and brandy subcutaneously, and radiant heat was applied. Next day breast-feeding was resumed. The wound healed satisfactorily. For a week after the operation the stools were green.

The infant was discharged on the twentieth day after admission. The general condition was good and he had gained about 14 ounces. The wound was healed and the hernia appeared to be completely cured.

I saw the infant at the age of 4 months, when he weighed 11¼ lb.

I am indebted to Dr. J. D'Ewart, the medical superintendent, for permission to publish this case, and to Dr. A. V. Magee, for permission to use his notes.

Booth Hall Infirmary, Manchester.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

CITY DIVISION.

Neuro-syphilis.

A MEETING of the City Division was held on February 1st at the Metropolitan Hospital, when Dr. HAROLD LATHAM was in the chair. Dr. ANTHONY FEILING read a paper on the clinical aspects of syphilis of the nervous system.

Dr. Feiling distinguished four gross pathological changes produced by syphilis in the nervous system—namely, gummata, which were rare but were sometimes large enough to simulate tumours; syphilitic meningitis, which was common; a specific form of endarteritis which caused great narrowing of the arteries and led to thrombosis; and degeneration of the cells and fibres in the nervous system—a later effect of the syphilitic toxin. These were not met as pure forms, and might be divided roughly into two types—the meningo-vascular form, causing meningitis and arteritis obliterans; and secondly, the parenchymatous or degenerative form, sometimes called syphilis centralis, with degeneration in cells and nerve fibres. Meningo-vascular forms appeared in the first months or years of life, while the parenchymatous forms usually occurred at a much later period, seldom before the age of 10 or 20. If treated early the prognosis in the meningo-vascular form was good; but this was not the case with the parenchymatous type. Nervous symptoms appeared occasionally, but rarely, in the primary stage of the disease. Such symptoms and changes in the cerebro-spinal fluid were common in the secondary stage. Pains similar to the lightning pains of tabes might be present in any other types of syphilitic disease of the central nervous system. Occurring in bouts they might last for a few hours, one day, or even a few days. The pain attack might only occur for a few minutes at a time, and was comparable with the stab of a knife. Curious areas of hyperaesthesia of the skin were frequently associated with the pains. In the earlier stages the form of the disease was either meningeal or arterial or both; it was apt to occur soon after infection, in six months, or at any time up to five years. The first clinical condition was headache, which was apt to be paroxysmal and induced by exertion, such as stooping. It might be the only manifestation of the disease. Syphilis of the brain might occur early after infection and be mistaken for neurasthenia. Epileptiform fits in a patient over 25 were often syphilitic, as were many cases of Jacksonian epilepsy. Lesions of the cranial nerves were frequently syphilitic, and when the ocular nerves were affected the pupils might be unequal in size, irregular in shape, eccentric, very tiny, widely dilated, or of the Argyll Robertson type. Such changes in a doubtful case might give valuable help in diagnosis. The next most common sign in the early period was ordinary hemiplegia in young adults aged between 20 and 40; a sudden stroke with hemiplegia and without cardiac disease was usually syphilitic: it was a softening due purely to an endarteritis with consequent thrombosis. In acute transverse-myelitis acute paralysis came on within a few days. The pathological process was endarteritis of the vessels of the spinal cord leading to thrombosis and meningitis. The parenchymatous forms occurred late after infection, and included the spastic paraplegias, most of which were due to a mixture of pathological processes—a chronic meningo-myelitis. The thickening of the leptomeninges and degeneration in the lateral columns caused spastic symptoms. More chronic types were described as Erb's syphilitic spinal paraplegia. In nearly all meningo-vascular cases, and in half of the parenchymatous forms, the Wassermann reaction was positive. The cerebro-spinal fluid showed an increase of cells from 10 per cubic millimetre up to 200, or even more; also an increase in the amount of protein, mostly globulin, as well as a positive Wassermann reaction. Every case of syphilis of the nervous system required great care in treatment. Meningo-vascular patients could take salvarsan freely. For headaches mercury iodide was most useful. Salvarsanized serum might be very effective in cases of tabes which did not respond to ordinary treatment. Very severe and intractable cases of tabetic pains might be benefited by partial division of the spinal cord. Treatment of early stages of general paralysis by malaria, though of great value, was risky in advanced cases. The intravenous injection of a particular form of relapsing fever—the African tick fever—with reaction in two to four days was not so dangerous as malaria therapy. Inunction of mercury was the very effective, rapid, and well tried way of giving mercury properly, but required a skilled masseur.

Reports of Societies.

SURGICAL TREATMENT OF CHRONIC NON-TUBERCULOUS ARTHRITIS.

IN the Section of Surgery of the Royal Society of Medicine on March 2nd a discussion took place on the surgical treatment of chronic non-tuberculous arthritis. Mr. WARREN LOW *presided.*

DR. A. P. BEDDARD, *in opening from the medical side,* said that it was generally admitted that rheumatoid arthritis and polyarticular osteoarthritis were low-grade septicaemias, comparable with gonorrhoeal rheumatism—that is to say, the joint changes were primarily infective—but he doubted whether the same was true of monarticular osteoarthritis, in which, although there was generally an infective element, there were other factors also. As for bacteriology, he believed the micro-organism concerned to be the *Streptococcus longus*, more often of the viridans than of the haemolytic type. Years ago he saw cases which were undoubtedly pneumococcic in origin, but for some years in England, until recently, the pneumococcus had been more conspicuous by its absence. He looked upon rheumatoid arthritis as certainly septicaemic. The primary sites of infection were the teeth, tonsils, sinuses, alimentary canal, including gall bladder, the male urethra, and the uterus. He had occasionally seen fairly acute cases in which no site of infection could be found, and it might be noted how symptomless chronic infection of teeth, tonsils, and sinuses might be, and how small a local trouble could keep up joint changes once the process had been started. There were two sites of infection the treatment of which was very unsatisfactory. One was the uterus, and for a chronically infected endometrium there were but two treatments: curetting, which in his experience was perfectly useless, and removal of the organ, which was a confession of failure. The other unsatisfactory site was the alimentary canal, and here neither vaccines nor drugs nor diet nor Plombières treatment could be guaranteed to put an end to the infection. Surgery was very occasionally of value for this purpose, but was not infrequently applied without discrimination. On rare occasions he had seen a chronically infected gall bladder which had resisted medical treatment removed with advantage. He imagined it was true of any tube in the body that if it was infected and there was delay in the passage of material along it, there would never be an end to the joint condition so long as the delay existed. Speaking generally, he thought the medical treatment of early cases of rheumatoid arthritis and polyarticular osteoarthritis was fairly satisfactory, and that the progress of the disease could often be arrested and the patient be left with a fairly useful if slightly deformed joint. The signs of failure were persistent pain and deformity. Speaking as a physician, he had certain cases in mind which were medical failures—namely, cases of rheumatoid arthritis in which infection had not been controlled, the joints being liable to periodic acute outbreaks of inflammation, and cases of rheumatoid arthritis or polyarticular osteoarthritis in which infection had been controlled, and the joint was partially movable, but in which any except the most limited movement gave much pain.

MR. C. MAX PAGE said that, satisfactory as it would be to base treatment on a sound pathology, this was impossible, for they were singularly in the dark up to the

present with regard to these joint affections. In rheumatoid arthritis, an infective condition, he did not think that during the period of activity the surgeon had much scope, except in so far as he directed measures calculated to prevent the development of deformity. Occasionally a single joint was affected, and then surgical intervention was undoubtedly justified. In osteoarthritis it was generally agreed that the joint changes were produced as a reaction to circulating toxins rather than to the presence of micro-organisms in the joint membrane. The source of the toxins, of course, was a matter of great importance, and the removal of the focus which produced them should always be dealt with before surgery of the joint was undertaken. He had been interested in Dr. Beddard's remarks about the unsatisfactory results of surgical treatment of uterine infections. He had noticed in the series of osteoarthritic hips he had operated on in females that there was a tendency towards the presence of fibroids, and in three cases hysterectomy was carried out on that account. With regard to the technical possibilities in dealing with chronically infected joints, the excision of the joint surface or synovial membrane was not very difficult; it was only a question of deciding whether the infection had become generalized. The reasons for operating in the osteoarthritic group were (1) derangement of joint action; (2) joint pain; (3) progressive deformity. In the first of these conditions manipulative treatment might be tried sometimes with success. If pain and deformity were permanent features more extensive procedures must be carried out. The operations undertaken might be classified as follows: (1) complete excision of synovial membrane; (2) arthrodesis; (3) arthroplasty, rather a formal operation calculated to reproduce a working movable joint; (4) simple excision of the joint. Choice of operation depended less on the anatomical condition of the joint and the assumed etiology than on the age and general condition of the patient. In the young and middle-aged the aim should be not only to remove pain but to produce a supple joint, and stability could best be effected by establishing arthrodesis, and in the knee or hip he had a strong leaning towards this procedure. In the elderly and enfeebled the procedure should have preference which would guarantee relief from pain, entailing the shortest operation and the simplest after-treatment. His experience of arthroplasty as a formal operation at the hip was limited to five cases, it was carried out because the condition of osteoarthritis of the joint was bilateral; the results were not very good; in no case was full range of movement obtained, and in all cases the patient complained of a certain amount of pain in the groin, though not the old articular pain. Partial excision of the head of the femur he had practised in eight cases, and thought it a sound measure to adopt for elderly people or where both joints were infected. In operation on the hip satisfactory exposure was difficult; he thought the supero-external approach based on Murphy's method the most satisfactory.

Mr. R. C. ELMSLIE said that the cure of most forms of chronic arthritis remained chiefly the function of the physician, but the surgical principle of rest for inflamed structures required emphasis. There was fear that rest and immobilization of a joint would give rise to stiffness, but it was not the immobilization that produced stiffness, it was the inflammatory changes themselves. The principles guiding the best position for resting the individual joints had been clearly laid down by Sir Robert Jones, but the speaker thought there was one point in which splinting often went wrong. No joint should be fixed in an extreme position; the knee should be 5 degrees short of full extension, the wrist should be dorsiflexed without being forced back, and the fingers and thumb should be rested in the position that they assumed when grasping an orange or a large egg. Aspiration of the joint as a mode of treatment was perhaps neglected. Excessive tension within a joint might be dangerous; in certain joints a pathological dislocation might occur. He had seen three instances of dislocation resulting from pneumococcal arthritis of the hip within a year, and it would seem that such results could be prevented if the condition were recognized and the joint either aspirated or incised. When difficulty in splinting was found from the presence of severe muscular spasm, a plaster-of-Paris case, extending widely above and below the joint, applied while the patient was anaesthetized, was in his experience the only safe way of preventing contracture. The relief of pain was often the most important object in the treatment of arthritis. With long persisting pain and slowly progressing deformity, fixation of the joint by operation (arthrodesis) might be called for. The efficacy of this operation in the case of the hip was now very generally recognized, but patients were still seen too often with a painful, stiff, and adducted hip, or a flexed and stiff knee, in which all movement had been lost, going from one form of medical or physical treatment to another in the hope of cure, when an arthrodesing operation would render them comfortable in three months. Monarticular arthritis without much pain or bone change, but with certain restricted movements, was the most favourable condition for manipulation of the affected joints under an anaesthetic. When there was greater restriction of movement manipulation also would often help, but care must be taken that the active inflammatory stage was over, and the manipulation must not be too forceful. Another item in the surgery of restoration of function was the removal of such mechanical obstructions as loose bodies. Such removal, besides helping to restore normal use, assisted in curing the arthritis. Arthroplasty for arthritis must be considered as in the experimental stage; the great objection to it was that it might leave a fibrous ankylosis with a range of movement insufficient to serve any useful purpose but sufficient to cause pain.

Mr. WHITCHURCH HOWELL spoke of three stages in arthritis: the pre-infective stage, the ankylosing stage, and the ankylosed stage. There were certain signs and symptoms which preceded the actual onset of an arthritis. The majority of arthritics were very thin, with little subcutaneous tissue, and suffered from poor circulation. They had acid saliva and acid sweat, and when these were got alkaline their physique improved and their arthritis, if it had begun, diminished, and in some cases disappeared. He also suggested that a number of advanced cases could be tackled surgically by a method of coaxing the joints one by one. The most difficult cases were those in which there was painful arthritis of the shoulder-joint. The lower limb could be stabilized, and so could the wrist, and arthroplasty could be done at the elbow-joint, but with regard to the shoulder-joint, were they to stabilize it, or manipulate it, or what were they to do? He described one case in which, in a young woman, after three years of lying in bed, function was restored to the hip and the wrist.

Mr. ZACHARY COPE related two cases, both women, one of whom had not eaten with her hands for, he thought, seven years, and the other had not moved out of bed for the same time. The knees were flexed to about 45 degrees, and the arms were ankylosed at the elbow. In both cases, when the knees were straightened, the patients improved wonderfully in their general health, one of them greatly increasing in weight. When operating on such patients, at the knee for example, no true bone was found. The bone was like a shell of celluloid with butter in the middle.

The PRESIDENT (Mr. Warren Low) said that twenty-seven years ago, in a very acute attack of dysentery (probably bacillary) in South Africa, he himself got a multiple arthritis. With the exception of the fingers of one hand, all the joints of the extremities were involved, and for seven or eight months he was practically helpless. He remembered that he had a feeling that all the joint surfaces were extraordinarily soft and pulpy, and his instinct of self-preservation told him that he must not put any pressure on those surfaces. Further, he was anxious not to have them splinted or in any way confined, as he felt that there was danger of their becoming stiffened. In spite of temptations to do other things, he stuck to this line of treatment, and at the end of eighteen months he was able to walk about with a certain amount of comfort. Surgeon General Keogh told him at the time that in the dysenteric cases in the South African war about 3 per cent. had this multiple arthritis. Another officer who had a similar, but not quite such an extensive, involvement at the same time as himself, in the middle of an attack of dysentery, had his joints put into plaster-of-Paris, with

the result that they became very stiff, and when the speaker, then himself quite fit, saw this colleague some years later he found him with stalactite masses at the elbow, and he had the melancholy satisfaction of excising one of his elbow-joints. His own working hypothesis as to the pathology of these cases was that there were two factors at work—infection and mechanical injury—in very different proportions in different cases. In what might be called the rheumatoid condition it was mainly infection, in the monarticular variety probably the mechanical factor was a very large one, though he always felt that where there was marked infection there was apt to be an increased mechanical factor, for the joint surfaces, being softened, were susceptible to injury from pressure, which explained why these gross changes were found in the lower more often than in the upper extremities.

Mr. ELMSLIE, who was the only one of the openers to make any detailed reply, said that no doubt in the President's case fixation and immobilization would have led to a less satisfactory result than that which he had achieved by following out his own form of rest. But in another patient, less careful to protect his joints, there might be advantage from putting the limb in plaster-of-Paris, and he cited one case in which mobility had been regained in a badly flexed knee-joint after this procedure. But in splinting, as in every other form of treatment, discrimination had to be used in the individual case.

PLASMOCHIN AND MALARIA.

AT a meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on March 2nd, with the President of the Section, Professor R. T. LEIPER, F.R.S., in the chair, Dr. P. MANSON-BAHR read a paper on the action of plasmochin on malaria.

Dr. Manson-Bahr said that for nearly three centuries quinine had been regarded as a specific for malaria. Analysis had shown that its main effect on the malaria parasite was due to the alkaloid quinidine. The complete chemical synthesis of the quinine molecule had not yet been accomplished, but for some years German chemists had been focusing their attention on the synthetic production of some combination of the quinoline ring of the quinine molecule which would be more specific and less toxic than the natural drug. The Bayer company had succeeded in producing a complicated compound of this ring called "plasmochin." Preliminary experiments on canaries infected with bird malaria showed that injections of this drug rapidly banished the parasites from the circulation. Roehl found that with quinine injections given daily for six days, parasites appeared in the blood after ten to twelve days; while in untreated birds they appeared on the fifth day after infection. He had thus formed a "scale" of standards, and against this had tested a large number of different drugs. In this way he had found that plasmochin had a parasitotrophic action sixty times greater than that of quinine. One peculiar result was that the sexual stage of the parasite was most readily attacked—the exact opposite to the case with quinine. Shortly after this Sioli tested the action of this drug in therapeutic malaria caused by the benign tertian parasite in cases of general paralysis. Doses ranged from 0.05 to 0.25 gram daily; the latter proved too large, and caused a serious cyanosis with blue lividity of the skin and nails. The parasites disappeared from the blood in all the 60 patients treated. At first given in capsules, the drug was later administered in tablet form in daily doses of 0.1 gram. Finally, however, a dose of 0.02 gram in tablet form five times daily was shown to be best. The action of the drug on benign and quartian malaria proved to be rapid and satisfactory; relapses occurred in some subtertian infections. The drug was found to exercise a lethal effect on the "crescents," which entirely disappeared within a week. Better results were obtained in subtertian malaria by the combination of the drug with quinine (plasmochin compound—0.01 gram plasmochin with 0.125 gram quinine sulphate). Six tablets were given daily. Larger doses caused cyanosis, but more recently it had been found that cyanosis rapidly disappeared on subsequent quinine treatment; plasmochin and quinine seemed to be mutually antagonistic. During the past year Dr. Manson-Bahr had treated 18 cases with plasmochin and 10 with the compound. Although not yet a very large series, records had been kept with great care, and the cases had been followed in detail for nine months to a year after treatment. He found that in doses up to 0.08 to 0.1 gram daily benign tertian parasites rapidly disappeared from the blood within twenty-four hours, and when the treatment was continued for a week this disappearance seemed to be permanent; in the same dose it was not so effective against the subtertian parasite. In both cases the schizonts were first affected, and in the latter case the "crescents" disappeared within four days. The size of the spleen was reduced with extraordinary rapidity. Urobilinogen in the urine appeared coincidently with the administration of the drug, and persisted for several days. A deep cyanosis had been noted in some cases when doses of over 0.08 gram had been given daily; the cyanosis was due to a methaemoglobinaemia, which, if too intense, might develop methaemoglobinuria. Dr. Manson-Bahr then detailed the cases which he had treated with plasmochin (6 benign tertian, 4 subtertian, and 4 mixed infections). It was seen that the action of this drug on the subtertian parasite was not satisfactory and had to be reinforced with quinine. Cyanosis developed in 3 out of the 8 cases; this was undoubtedly a toxic symptom, apparently analogous with the methaemoglobinaemia of potassium chlorate poisoning, and seeming to occur in susceptible individuals after even a very small dose. The drug was free from bitter taste, and was not disagreeable to take. He then referred to cases of benign and of subtertian malaria which he had treated with the compound. The parasites did not disappear so quickly from the blood, but the improvement in clinical condition was striking. No unpleasant sequels were observed. So far as his experience went, the compound was more efficacious in subtertian infections than the pure drug. From his success in these cases Dr. Manson-Bahr thought that a definite addition had been made to the therapeutics of malaria. Some of the original disadvantages of plasmochin had been removed by the addition of minute quantities of quinine, and he was sure that finality had not yet been reached. This drug was probably only the first of a series of synthetic drugs which might destroy the parasite without causing any toxic symptoms; it must be regarded as the beginning, not the climax, of a new series of antimalarial drugs.

Dr. J. GORDON THOMSON drew attention to the fact that both natural and acquired immunity to malaria existed. The latter was a tolerance which developed after repeated infections over a long period, and occurred where the disease was hyperendemic. If such persons were removed they lost this. In avian malaria the bird had an acute disease for about nine days; after that the disease decreased, and a partial tolerance was developed which might remain for nearly two years. The blood, however, was still infective for other birds and for mosquitos. The bird was not cured, and if its resistance fell the disease might again become acute. Dr. Thomson asked whether plasmochin really cured the disease or merely caused a tolerance. Natural immunity in malaria also existed, and some patients recovered without any specific treatment. These facts would have to be taken into consideration before plasmochin could be said to have any advantages over quinine. Plasmochin seemed to be of little use for malignant tertian malaria, which, however, was more amenable to treatment with quinine than benign tertian. The factor of safety of the drug appeared to be very low—a fact which was a definite disadvantage.

Sir WILLIAM PROUT stated that it was very rare indeed to find a true quinine idiosyncrasy, although many people thought that they were unable to take quinine. He had treated thousands of cases of malaria, and he had found that the inability to take quinine was so rare as to be negligible.

Dr. MANSON-BAHR, replying to the discussion, stated that this was the first time that a synthetic drug had been prepared which had a specific action on malaria. Although

it was not yet entirely satisfactory, he had little doubt that ultimately some similar drug, without the disadvantages of this one, would be found.

This discussion was followed by an essay on onchocerciasis (worm nodules in man in Africa) by Dr. DYCE SHARP, and a note by Professor LEIPER on the discovery in the Belgian Congo of the species of *Physaloptera* previously recorded by himself in other parts of Africa.

GENERAL ANAESTHESIA IN DENTAL OPERATIONS.

AT a meeting of the Anaesthetic Section of the Royal Society of Medicine on March 4th Dr. BELLAMY GARDNER opened a discussion on general anaesthetics in dental operations.

Dr. Gardner said that the dental surgeon needed an anaesthetic which would enable him to perform any dental operation in his own surgery. The nursing home was to be used only as a place in which the patient could recover from the effects of the operation and anaesthetic under the care of a skilled nurse. The nurse should be present at the operation and accompany the patient to the home afterwards. Operations in a nursing home were inconvenient, as most dental surgeons were not accustomed to operating upon patients in the horizontal position. Few nursing homes possessed dental chairs, and it was difficult for a dentist to use portable hired dental chairs with which he was unfamiliar. It was therefore necessary to secure an anaesthesia sufficiently deep and prolonged to perform any dental operation, and to allow the patient to return either to his own home or a nursing home within a reasonable time, such as an hour from the commencement of the induction. The anaesthetic employed would vary according to the length of time needed for the operation. For an operation lasting up to fifteen minutes nitrous oxide and oxygen sufficed; in any longer operation the addition of ether and chloroform was required. It was safe to give chloroform in the upright position so long as this anaesthetic was started with the patient sitting up, but a danger was introduced by changing the position to the upright after commencing with the horizontal. Before induction with nitrous oxide the patient should be asked to blow his nose to free it from mucus; he should then be seated in the dental chair with his back well up against the back of the chair. His feet should be placed on the floor, one on each side of the foot-extension of the chair, and a stout leather band should be passed over his thighs and secured to the pedestal of the chair so as to maintain this position even if he made a few spasmodic movements during the induction. The headpiece of the chair should be arranged so as to support the occiput, and then the patient's heart should be auscultated through his clothes. The surgeon should be asked to begin on the patient's left side with the prop inserted on the right side. In this way it was often possible to slip the prop over to the opposite side without the use of a Mason's gag, and, as the anaesthetist was standing to the left of the patient, this manœuvre was easier than if the prop was inserted on the left at first. Many sponges about the size of a small orange should be available, and as soon as the patient was under the anaesthetic one should be passed into the mouth to act as a velum at the back of the tongue and prevent blood or fragments of tooth or filling entering the throat. As soon as the left side of the mouth had been dealt with a second sponge should be placed on the left to mop up the blood. On completion of the operation the sponges should be removed, the head pushed forward, and finally the gag or prop removed. If ether or chloroform had been used the chair should be flattened out so as to allow the patient to recover in the horizontal position. The use of artificial daylight or a searchlight was not to be recommended, as thereby valuable information as to the colour of the patient was lost. After-effects were least marked in patients who were free from all cyanosis. In the case of an alcoholic patient it was often possible to give a smooth anaesthesia with nitrous oxide and oxygen if a preliminary fairly large dose of morphine were given. This form of anaesthesia was contraindicated in paralytic patients and in anginal cases, both of which were best anaesthetized with chloroform in the horizontal position.

MR. IVAN SPAIN, speaking from the point of view of the dental surgeon, said that for patients between the ages of 10 and 65 in operations lasting from three to five minutes he preferred nitrous oxide and oxygen to be given, but for those older than 65 he hesitated to advise nasal administration. In the case of children under 10 years of age he endeavoured to operate in their home under a mixture of ether and chloroform. He did not like ethyl chloride. For long operations he preferred the nursing home. A dental chair, if of suitable design, was useful, but he found the theatre table quite satisfactory if the mouth were packed with suitable sponges to prevent the swallowing of foreign bodies. The chief drawback to nasal administration was the frequent complaints of patients that they felt suffocated; he believed that this was usually due to the gas being administered under pressure at too early a stage of the anaesthetic. If the mouthpiece was not used and the pressure in the bag was kept low until the patient was practically unconscious, a satisfactory anaesthesia could be obtained in 80 per cent. of cases by the nasal method. He believed that the gag should be operated by the dental surgeon, who could see what he was doing, and the same held good with regard to sponges.

Dr. Z. MENNELL (President of the Section) believed that the natural light lamp exaggerated cyanosis. In his experience the necessity of a clear airway was not always recognized by the dental surgeon. Morphine prolonged the anaesthesia, but also was likely to make the patient sick. Dentists should take care to teach the public that not every doctor was also a skilled anaesthetist. Chloroform was not a safe anaesthetic to give in the sitting posture. The feeling of suffocation could be modified if the nosepiece were not pressed into place at the beginning, but held over the nose until the patient was beginning to get under the influence of the gas.

Dr. I. MAGILL expressed the opinion that the ideal anaesthetic for a long dental case was intratracheal anaesthesia by means of a catheter through the nose. A double tube should be used to allow for expiration.

Mr. H. P. BAYLIS recommended ethyl chloride on an open mask as a suitable anaesthetic for children. He found a theatre table quite ideal for dental operations as the surgeon could move round the patient. The anaesthetist should leave the lower jaw alone. If gas were given by the nasal method the patient need not be deeply under for short cases, as it was always possible to deepen the anaesthesia if required.

Dr. S. R. WILSON believed that dental anaesthesia was far behind the level of the anaesthesia in general surgery. Patients expected the anaesthetist to give a safe, comfortable, and cheap anaesthetic when the operation was a dental one no matter how difficult that operation might be.

Mr. J. G. TURNER thought that the nursing home was the best place for a dental patient. Sometimes a dental chair could be found there, but the theatre table was quite as good as the chair, if not better. He doubted if the intratracheal tube was ever really necessary. He wondered why it was considered necessary to use oxygen when air was freely available, and why ethyl chloride was banned. Was it really unsafe for children? He objected to chloroform being given in the upright position. He preferred general to local anaesthesia when dealing with long operations on the lower jaw, as the patient was saved much of the after-pain due to prolonged tension on the muscles of the lower jaw. Patients seldom complained of this after-pain following a general anaesthetic.

Mr. H. E. G. BOYLE preferred to give anaesthetics for long cases in nursing homes. He condemned the use of straps as being a confession of failure; such treatment was apt to scare patients. He did not like sponges; the mouth could be kept quite dry by the intelligent use of a sucker. Ether and chloroform were usually quite unnecessary, but ethyl chloride was useful for small children. Except in a few cases of massive extraction, endotracheal anaesthesia was unnecessary. He wondered why dentists did not make more use of anaesthetists for the purpose of procuring analgesia for painful drilling.

Mr. S. STEADMAN questioned the use of oxygen, as there was more movement of the patient when it was used, and the after-effects were more pronounced. He emphasized the necessity for the proper preparation of the patient before an anaesthetic; a meal should be taken about two hours before it. Analgesia for teeth-filling by nitrous oxide had been superseded by local injection. Ethyl chloride was excellent for children, but the bag should be applied to the face before the drug was put in, to avoid excessive dosage at first should the child struggle.

Dr. F. E. SHIPWAY believed that ethyl chloride given by the open method was quite safe; at Guy's Hospital it had been given in 15,000 cases without a fatality. He condemned operation in the dental chair.

Mr. FRANK COLEMAN drew attention to the possibility of administering gas and ether by the nasal route. The intratracheal method was certainly good at times. Sponges were most useful. Analgesia by gas had been superseded by local anaesthesia.

Dr. C. J. LOOSELY explained his idea of administering gas and ether by the nasal route, his apparatus being a modification of the Clover inhaler. He did not believe that nausea following nitrous oxide was in any way related to food or to overdosage, but was due to idiosyncrasy on the part of the patient. Sponges were certainly most useful, but should not be pushed too far back; the placing of sponges should be the work of the dentist.

Dr. J. F. TREWBY had found that morphine made the breathing of the patient more difficult, and had obtained better results with large doses of bromides, especially in the case of the highly strung. In anginal cases the operation should be performed at the patient's home in the presence of the patient's doctor, ether being more suitable than chloroform. Care must be taken that sponges were free from mucus and blood, as when slimy they were easily swallowed; he therefore always had sponges slung together with tape or string. Sterilizers should be kept well away from the scene of the operation, as otherwise they might be overturned by a refractory patient; an action for damages might then lie against the dentist and doctor if the patient were scalded or otherwise injured. Care should be taken not to stretch the cheek unduly when using the Mason's gag. Teeth were apt to be smashed by the operator not having sufficient room to work in. Dr. Trewby mentioned a case of keloid scar following bruising of the lip during a dental operation, and thought that in this case an action for damages might have lain against the operator or the anaesthetist. He also quoted a case illustrative of the curious mental condition which might follow nitrous oxide anaesthesia. The patient, while not losing her memory completely, could not remember her name. She tried to walk under a taxicab on leaving the surgery, and, when knocked down and put in the cab to be taken home, could not give her name or her address, though she was able to give that of a relative, in whose house she eventually came to her senses.

THE BREAKDOWNS OF MIDDLE LIFE.

THE Section of Balneology and Climatology of the Royal Society of Medicine held a discussion on the breakdowns of middle life, on March 3rd, Dr. R. ACKERLEY presiding.

Dr. J. CAMPBELL MCCLURE said that they were all familiar with the hustling young man who tended to slow down very noticeably in early middle age, and might be unresponsive to new impressions by the early forties; also with the fact that sudden death or nervous breakdown occurred in the apparently physically robust in early middle life. In contrast there was the steady maintenance of capability—or even its increase—on the part of some who in early life had not been remarkable for their powers of achievement. Middle age was for most a time of failing power in one direction or another, and when a man went on running a fifty-year-old brain and body as if it were only a thirty-year-old the time would come when a good average mechanism would break or show signs of premature wear simply because the period of full activity, mental, bodily, and emotional, had been carried beyond the normal point of safety. Breakdowns in middle age were due to two main causes: a local vulnerability of tissues, which varied in different individuals, and a general failure in the vitality of the organism as a whole. Failure of vitality laid the organism open to attack. The normal diminution of power in middle age was largely due to the failure of certain endocrine glands, and when to this normal failure was added the disturbance produced by the continuance into middle age of indiscreet habits of diet and the like, breakdowns more or less serious occurred, affecting one or other somatic system according to the personal vulnerability of the patient. He thought that this vulnerability of various tissues was determined by biochemical faults, either of deprivation or excess, which could be corrected by treatment on chemical lines, such treatment, of course, being combined with careful dieting. It was important to see that elimination was adequate to tissue change, and to estimate the capacity of the kidneys, skin, and liver, and adapt the patient's life, dietetic, occupational, and climatic, to suit that capacity. Breakdowns in middle life due to overstrain of a normal body were beyond the power of the physician to prevent, but those occurring without such abnormal strain were preventable in very many cases by the recognition in early life of constitutional tendencies, which indicated either a biochemical or an endocrine abnormality. The systems attacked might be the lungs, the heart and blood vessels, the nervous system (especially the vagus), the gastro-intestinal tract, the liver or kidneys, the joints, or the interstitial fibrous tissue, and beyond all these declared lesions was either a congenital fault of chemistry or internal secretion or a severe acute disease which had weakened endocrine capacity or disordered the glandular system. Breakdowns, therefore, were complicated things, involving questions of general resistance and local vulnerability; they were capable of prevention rather than of cure, while at the same time the conditions co-operating in their production were more often than not capable of satisfactory modification if the cases were not allowed to drift for too long.

Dr. R. WYBAUW (Spa, Belgium) spoke of the systolic activity of the arteries and its influence on the circulation. He said that one of the most common troubles of middle age was high blood pressure, and the best treatment, except diet, was spa treatment, but the present knowledge as to the action of baths and cures on the circulation was not adequate. The present theory of the circulation, which considered the heart as the only motor for the movement of the blood, and the arteries as elastic tubes whose muscles had no other task than to regulate the diameter of the vessel, did not give an exact explanation of high blood pressure. A new theory, which he had tested by experiment, was that the arterial wall, immediately after the pulse wave had reached the artery, gave an active constricting response, and his conclusion was that hyperpiesia was a disease in which the sensibility of the artery was greatly increased and its muscular response exaggerated. This exaggeration was also the reason why in hypertension the blood pressure was very often higher in the legs than in the arms. Balneological treatment certainly calmed the hyperaesthesia of the arteries, since after the cure the difference between systolic and diastolic pressures was diminished. It was possible that the reflexes of the arterial wall were under the control of nervous systems acting as the vagus did on the heart.

Dr. R. FORTESCUE FOX said that his view was that the variable and curious conditions found in middle life were not separate diseases at all, but a general disturbance. Moreover, the evidence went to show that they originated not in any particular organ, but in some change in the fluids of the body. The most severe cases were found in the decade from 45 to 55 years, a period of physical involution and adjustment both in men and women, and on this well prepared field of lost immunities there came the invasion of the micro-organism. A general disturbance of the equilibrium of health, with disorders of many functions, due to epoch, strain, injurious habits, and micro-organisms, led on naturally to more serious and permanent disorders and tissue change in the most susceptible patients. There was a very large and perhaps increasing number of cases in which the simple remedy of change of habit, regulated rest and exercise, fasting, elimination of alcohol, saline

and Turkish baths, was insufficient, and from this class of cases the health resorts drew large numbers of their more serious visitors. At many resorts a tonic or sedative climate was itself a remedy of no mean importance, especially when combined with regulation of diet, rest, and exercise in the open air. The spas, however, offered far more than this in their internal and external treatment with a variety of waters. The adjustment of the remedies of the spa and the health resort to the diseases of middle life was a very fine art, and if the spa practitioner could study the circulatory and nervous reactions effected by baths, the treatment could sometimes be modified from day to day with much advantage. Baths and waters—like strychnine, bromides, and arsenic—were edged tools, and their choice and dosage must be guided in every case by the reactions observed.

Dr. W. J. TYSON was doubtful about the elaborations which previous speakers had brought to this subject. His view was that middle-aged people might be divided into three classes: those who were never young, those who had forgotten that they were ever young, and those who were still young. The middle-aged man, if he had not got by his time of life sense enough to know how to live, had better throw up the job. The man of 45 ought to know how to order his habits in view of his limitations, and to take the food, exercise, and work which he knew was suited to him. One important thing was to have a hobby in early life, otherwise middle age became stupid, useless, and provoking. Middle age was a time in which the physical powers were going off, but the mental powers went on developing until 70 or later, and as for character, that was never finished.

Dr. H. A. ELLIS said that the normal person was the one who grew old in step with his years, and there were two abnormals—one the person who was never young, and the other the person who never grew old. The normal person had a balanced intake and output at the start of life. His functions of assimilation and elimination were perfect. The abnormals had an error in one or other of these respects. Life was "an acid phenomenon in an alkaline medium," and the business of the medium was to keep the acid in control. The person with elimination difficulties was a person of the acid type. The urine of these different types was quite distinctive. Acid was eliminated in the urine in two ways—as free acid and in combination with ammonia as a salt. In the normal person, who grew old judiciously, the ratio of ammonia acid to free acid was 2:1; in the person with acid accumulation and metabolic stress, who started life too old and ended in middle life, it was 1:1, and in the person who started life with assimilation errors, and remained abnormally young in old age, the ratio was 3:1. Most of the physician's work lay with people of the acid type—people who had a difficulty in getting rid of the acid which produced certain definite constitutional effects, hence rise in blood pressure, higher differential pulse rate, and the ordinary symptoms of cardio-renal trouble. The kidney function was controlled by acid elimination. A man was said to be as old as his arteries, but it was more true to say that he was as old as his kidneys, because it was the kidneys which controlled the arteries. The speaker showed charts illustrating the acid relations in the morning urine—the sample taken on rising and the "tide" urine taken two hours later, and added that as for the second class of abnormals, who had assimilation errors, they usually had low blood pressure, they did not suffer from night micturition, as the persons of the acid type frequently did, and their differential rate was below 44. But they got fatigued, tired, and incapable. It was their endocrines which were at fault, and a balance was as necessary in the endocrine system as in acid elimination.

Dr. LEONARD WILLIAMS said that nature intended man to be a hunter and fighter, but the conditions of civilized life were such that the surprising thing was, not that breakdowns occurred, but that they occurred relatively so seldom. It was difficult enough in any case for a man to keep himself in physical fitness, and after the age of 25 it was made more difficult by the entrance of the "villain of the piece," the woman that God gave him! Then a man had to reduce his pace to the pace of pregnancy or the perambulator or both. Worse still was that tendency in woman which impelled her to "feed the brute," so that the sedentary man who ought to keep himself in a condition of physical fitness became fat and puffy, and developed high blood pressure and various horrors because he could not redress the balance. In the end he went to a spa, which would do him an enormous amount of good, if his wife did not go with him. At the spa he had a chance to increase his elimination, but there was no use in that if he did not manage at the same time to reduce his intake. The first thing the spa physician should do was to starve the patient for a week and purge him thoroughly. Breakdown in middle age came sooner or later, and the only way to delay it was to reduce intake and increase output.

Dr. W. P. KENNEDY thought Dr. Leonard Williams had gone a little too far in his indictment of women. Monotony of diet, from which bachelors especially suffered, was a bad thing, and he had seen good results from putting such men on more varied food.

Two visitors from abroad took part in the discussion. Dr. MOUGEOT of Royat supported Dr. Wybauw's hypothesis with regard to pressure and the arteries, and also suggested that balneological treatment acted by calming the sympathetic system in every part of its large area and reducing high blood pressure. Dr. FERREYROLLES described some recent work done at Vichy in the way of experiments upon mineral waters as an antidote to toxins. It appeared that they had a certain capacity for destroying organic poisons.

Mr. H. L. A. ATTWATER said that the urinary passages in health were extraordinarily immune from the invasion of bacteria, but if there was stagnation in the tract the passage was liable to bacterial attack, and stagnation was favoured by slackness of muscles of the abdominal wall and back which became infiltrated with fat. Some cases of stagnation could be dealt with by surgical means, but it was for the spas to deal with cases of sedentary slackness.

Dr. ACKERLEY, from the chair, said that the explanation of many breakdowns was not far to seek. The modern day was prolonged by artificial light, modern life was full of a multiplicity of interests without sufficient rest. The very fact that a large proportion of people had to be "called" in the morning—hardly one in ten was capable of rising without this stimulus—showed that their period of sleep had not had its proper recuperative effect, and by the time these persons got to 40 or 50 they were really old because of the amount of rest they had forfeited. One of the virtues of the spas was the element of rest which they induced.

Dr. MCCLURE, in replying, said that one great factor in the success in balneological treatment was the effect on the skin brought about by waters of various temperatures so that, on the one hand, a very active sympathetic system was calmed, and, on the other, a jaded and exhausted vagus system recovered. In high blood pressure a good effect could be obtained by using fairly hot water, and in low blood pressure the skin would respond best to water of a moderate temperature.

CORTICAL NECROSIS OF THE KIDNEY.

AT a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, on February 18th, with Mr. EARDLEY HOLLAND in the chair, Dr. ARTHUR CROOK read a paper on cortical renal necrosis.

Dr. Crook described a case in which cortical necrosis of the kidney followed labour. The condition had been associated with suppression of the urine; this was successfully treated by decapsulation of the right kidney, and the patient recovered. Portions of the kidney were removed during the operation, and, on microscopical examination, areas of focal necrosis were detected in the cortex.

Mr. CLIFFORD WHITE, discussing the condition, said that he had incised the renal capsule on two occasions for anuria in eclampsia, with good results. In two other cases no operation on the kidney was undertaken, and both patients had died. He described a case of incision of the capsule of the kidney for suppression of urine following eclampsia.

Dr. J. BAMFORTH discussed the microscopical and pathological findings which were associated with this condition, and gave an account of the changes in the kidney preceding the onset of necrosis.

Professor MUNRO KERR thought that the cortical necrosis was superimposed on an old chronic lesion of the kidney.

Clinical Demonstrations.

Mr. GORDON LUKER showed a specimen of an ovarian pregnancy with the gestation sac and foetus lying in the middle of an ovary which was the size of a hen's egg. It had been removed from a woman, aged 35, the mother of two children, the younger being 17 months old. The clinical history included eleven weeks' amenorrhoea, towards the end of which abdominal pain and intermittent haemorrhage supervened. Mr. Luker also showed two specimens of sarcoma of the uterus arising in fibromyomata. One had occurred in a married woman, aged 53, who had two children; the other in a single woman, 40 years old.

Dr. ALICE BLOOMFIELD reported a case of cyst of the urachus in a single woman, aged 35. It was about the size of a sixteen weeks pregnant uterus, and ruptured during abdominal examination. After removal the patient made an uninterrupted recovery. From the history it appeared likely that some time previously another rupture had occurred. Dr. Bloomfield also described the occurrence of a patent Wolffian duct in a parous middle-aged woman, who complained of vulval irritation. An opening was found between the vaginal and urethral orifices, and the duct was patent for four inches.

TREATMENT OF BILIARY INFECTION WITH HEXAMINE.

AT a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on March 8th the subject of the treatment of biliary infection with hexamine was brought forward by Dr. A. F. Hurst and Dr. F. A. Knott—the one from the clinical and the other from the experimental point of view.

Dr. HURST said that hexamine had been used for many years as a urinary antiseptic, in which respect it was well known that it acted only in acid urine. It was always supposed that acid urine split the hexamine and set up free formaldehyde. About twenty years ago it was noted that hexamine was excreted in the bile, and as a result of that observation hexamine began to be given as a biliary antiseptic, in spite of the fact that bile was alkaline. Only small doses, however, could be given because of the irritating action on the bladder. In his own clinical experience he found that even these small doses were of use in cholecystitis or biliary infection, but six or seven years ago it was suggested to him by Dr. Ryffel that large doses of alkali might be given with the hexamine so as to make the urine alkaline and thus neutralize the bladder effect, and in that way large doses of hexamine could be given because no formaldehyde was set free in the bladder. He therefore gradually increased the doses of hexamine from 10 or 15 grains up to, finally, 100 grains three times a day, giving sufficient alkali to keep the urine alkaline, and doses of this range had been given for weeks or even months. He gave a patient 100 grains of hexamine dissolved in 1 oz. of water, and in another ounce of water a drachm of sodium bicarbonate and a drachm of potassium citrate. The first dose was given after breakfast, the second after tea, and the third the last thing at night. The purpose of the bicarbonate was to prevent the splitting up of hexamine by the acid in the stomach. For safety's sake he generally began by giving the whole dose of alkali, and but half the dose of hexamine. Actually as much as 600 grains a day had been given, in an attempt to discover how far the hexamine could be pushed without bladder irritation. Many cases, in his hands and in those of his colleagues, of undoubted cholecystitis got well with this treatment, but the mystery remained as to how hexamine, which would not act in the alkaline urine, acted in the alkaline bile. Dr. Knott, who had confirmed the excretion of hexamine in the bile, had shown that *B. coli* or some aberrant form of that organism was responsible for the common infection of the gall bladder. Streptococcic infections were exceedingly rare, in spite of what had been said on this subject in America. Fortunately it was on the coliform bacilli that hexamine, or rather formaldehyde, was an active antiseptic. The average case of chronic cholecystitis in which there were no gall stones responded well. Even when gall stones were present and were causing symptoms, should there still be an infection of the biliary passage—generally the gall bladder had become sterile by this time—a preliminary treatment with hexamine before operation disinfected the gall bladder and made the operation more safe. After operation also the treatment should be continued, for it was not uncommon for biliary infection to involve all the biliary passages and not merely the gall bladder.

Dr. KNOTT said that urotropine was a particularly easily dissociated substance. A hydrogen concentration of *p*H 6 would produce 1:4,000 formaldehyde, which was a definitely antiseptic solution. Formaldehyde was one of the slow-acting antiseptics. If one subjected it immediately to the Rideal-Walker test it might appear to be not particularly powerful, but if allowed to continue for a considerable time it attained a strength as high as or higher than phenol. If broth culture containing a certain amount of urotropine were infected with *B. coli* the organisms would go on steadily growing and producing acidity, and the acidity would rise to *p*H 5, which meant that a considerable amount of free formaldehyde must be present and, of course, exerting an antiseptic action. In bile the antiseptic action was exerted rather better and more quickly and by a lower strength of hexamine than in broth culture or any alkaline medium in which organisms would grow. The greater effectiveness of formaldehyde in the presence of bile salts was probably due to the lowering of the surface tension, which allowed the formaldehyde to act upon or come in contact more efficiently with the bacteria and so destroy them. Practically all his experiments had been on coliform infections, though he had also obtained with streptococci quite definite evidence of inhibition. The production of local acidity, the fact of a lowered surface tension, and possibly the mechanical situation of the bile in the gall bladder and its mucous content, were the reasons why hexamine was able to dissociate and exert its antiseptic power in bile, whereas it was not so efficient in fluids not containing bile, or in mild alkaline media of any kind.

Dr. GEORGE GRAHAM (President of the Section) was sceptical as to the value of hexamine, whether in urinary or gall-bladder infections, and quoted Peyton Rous to the effect that the function of the gall bladder was to concentrate bile, that there might be as great a concentration as ten times, that the bile itself as secreted from the hepatic ducts remained alkaline, and that the gall bladder itself made the bile acid. Peyton Rous had said that he did not think hexamine would have any action in the gall bladder except in health. Dr. E. P. POULTON had shared Dr. Graham's scepticism until some Copenhagen experience had led him to think there might be efficacy in hexamine. Dr. KINGSTON BARTON had found hexamine of value in old people with gall-bladder trouble, whose cases were unsuitable for operation.

Dr. HURST said that with regard to the power of the gall bladder to concentrate bile in these cases of cholecystitis, as a routine in all suspected cases cholecystography was done and a good shadow of the gall bladder was obtained, showing that the gall bladder was still able to concentrate the bile. He thought that inability to concentrate bile was shown only in a very advanced stage of cholecystitis and in conditions obviously calling for surgical measures. With regard to small doses of hexamine, clinically it was his experience many years ago that these had a good effect in some cases of cholecystitis, but certainly his impression was that with the larger doses, given with alkali, the results obtained were still better, and it would naturally be assumed that if 300 grains could be given a larger proportion would reach the gall bladder than if the amount were 30 grains.

ACUTE ABDOMINAL CONDITIONS IN PREGNANCY.

At a meeting of the Medical Society of London on February 28th a discussion on acute abdominal emergencies complicating pregnancy and the puerperium was introduced by Dr. J. S. FAIRBAIRN, whose paper is printed at page 456 of this issue. Dr. Fairbairn was to have been followed from the surgical side by the late Mr. Joseph E. Adams, who died on December 21st last.

Dr. J. M. WYATT dealt with acute abdominal conditions during the puerperium. He quoted figures from the Metropolitan Asylums Board's scheme for treating puerperal sepsis in fever hospitals. Out of 240 cases 40 had peritonitis. He emphasized the importance of the pulse rate, advising laparotomy when the pulse was over 120 and indications of general peritonitis were present. He considered intrauterine instrumentation to be contraindicated. The difficulty in the early puerperium of distinguishing between acute appendicitis and a septic condition in the generative tract favoured an expectant attitude unless urgent surgical intervention was imperative. In the treatment of general peritonitis Dr. Wyatt advised drainage of the peritoneum without swabbing or lavage. He laid stress on the advantages gained by the use of anti-*B. welchii* serum in these cases.

Dr. J. P. HEDLEY mentioned cases of fibroids and ovarian cysts which had been damaged during labour, causing acute symptoms. One particularly puzzling case of constipation during pregnancy almost exactly simulated an acute abdominal condition.

Dr. ETHERIDGE discussed the origin of pyelitis in pregnancy. He thought it probable that it was a bowel infection, or that some septic focus in the mouth or sinuses might be responsible. High temperature and rigors distinguished pyelitis from retro-caecal appendicitis. If alkalis were not effective he advocated washing out the pelvis of the kidney with a solution of 1 in 1,000 silver nitrate through a ureteric catheter. One or two washings almost always brought the temperature to normal.

Dr. F. J. MCCANN described a case of complete volvulus of the small intestine in a patient five months pregnant. He considered drainage in the flank of first importance in appendix abscess, and advocated jejunostomy with caecostomy for toxaemia in severe puerperal septicaemia.

Mr. ZACHARY COPE described a case of early pregnancy with subperitoneal fibroid causing pain and vomiting and bulging in the inguinal region, which had been mistaken for a strangulated hernia. He mentioned that the intense abdominal pain following a septic criminal abortion, combined with the misleading history the patient often gave in these cases, was a pitfall for the unwary. He commented favourably on the benefits he had seen resulting from the use of anti-*B. welchii* serum, introduced by B. W. Williams.

VISUAL IMAGERY.

At a meeting of the Royal Medico-Psychological Association on February 16th, at the Cheshire County Mental Hospital, Macclesfield, with the President, Dr. J. R. LORD, in the chair, Professor T. H. PEAR read a paper entitled "Recent investigations of visual imagery, with special reference to hallucinations."

The contribution was in two parts, the first dealing with modern experimental normal psychology, the second with modern psycho-pathology, and Professor Pear said he was not aware of any writings which attempted to bridge the gap between the two. German investigators had been very busy on this subject since the war, and some of their results were now becoming known in this country. Some people were able to visualize vividly things seen, such as pictures, maps, and diagrams, and were seldom conscious of having mistaken the images so conjured up for the realities. The popular view was that the man who mistook images for realities was insane, and he who did not was not insane, but this did not suffice for a psychological definition, for dreaming was within the experience of most people. Not only in dreams, but in other borderline cases the imagery was very real, and the images in a dream might be quite different from the images perceived in the day-time. In ordinary everyday life, though a very clear distinction was made between percepts—experience of the outer world—and what were termed images, they were interdependent. In the case of a motorist passing another motor in the night when the lights of the other car were not switched off, it was not an illusion that the driver of the first car saw the lights after he had passed them; he actually continued to see them, for the visual mechanism was still active. There were many problems concerning a form of visual memory which was neither an after-sensation nor an ordinary visual image, and this visual memory was termed the ideatic image. It was a special memory of an object seen which some people experienced after the object itself had been removed. It was not ordinary memory because details came out in the ideatic image which were not consciously observed in the direct examination. This merged into the region of pseudo-hallucination. To produce an after-sensation it was necessary to fix the eyes carefully on one spot in a picture for about half a minute, and then continue to fix on the same spot for about twenty seconds after the picture had been removed. The after-image had not the same colours as the original. No one perceived the ideatic image just as in the picture; those who saw it said that it fluctuated, sometimes being clear, at other times less clear. People who got the ideatic image were often those who were devoted to art; some were classed as "unusual" people. In Germany it was found that after the fourteenth year the tendency to experience these images decreased with the passage of the years, unless the adult had the childish type of mind. With regard to the relation of this phenomenon to pseudo-hallucination, Professor Pear reported a remarkable experience in a man who worried about his hallucinations following the war. These ideatic images might occur when the mind regressed to a more childish state, and it was an interesting question how far the modern system of education and culture had educated people out of this habit.

Dr. SHAW asked whether this ideatic memory was not the same as was spoken of as the artist's memory, and Dr. DONALD ROSS inquired whether Professor Pear had thought of investigating the auditory sphere in the same way as the visual, since auditory hallucinations were the more serious of the two.

Professor PEAR replied that the ideatic image was not the same as the artist's memory, and many artists did not have a visual imagery while they were drawing. A man who had satisfying visual images did not have the desire to draw at all. It seemed that the investigation of auditory pseudo-hallucination was an almost untilled field; these manifestations were usually regarded as grave.

Ultra-violet Radiation in Mental Therapeutics.

Dr. K. K. DRURY, in a paper entitled "Ultra-violet radiation in mental hospital practice," said that the Board of Control reported in 1925 that there were, at that time, only five installations of artificial heliotherapy apparatus in mental hospitals. In the first part of his paper Dr. Drury reviewed the history of the use of the photochemical action of light. The maximum power of the light was exerted when the rays fell at right angles to the surface receiving them, its intensity decreasing with the acuteness of the angle of incidence. For this reason in the latitude of this country only a partial effect was obtained, and hence artificial means of production of more or less equivalent rays was needed. The three main types in use to-day were the carbon, the tungsten, and the mercury vapour arcs. The first of these was used almost exclusively in the Finsen Institute, Copenhagen; it enabled large areas to be irradiated, and several patients could be treated at once. Water cooling was necessary. The tungsten arc was apt to splutter, and required much attention; it did not seem to be a good type for work in a mental hospital. Of mercury vapour lamps, the vacuum type had several disadvantages, but the atmospheric air-cooled type was the simplest and cheapest, as well as the best adapted for local applications. It was very well suited to the needs of a mental hospital. There was no spluttering nor great heat, and no noxious fumes were given off. In the Chester County Mental Hospital bathrooms and dressing-

rooms were in close contiguity, and it was found that bathing facilitated the treatment. Crookes glasses were worn to afford protection to the eyes from indirect rays. Patients subjected to this treatment were benefited in their general health; the bactericidal power of the blood was increased, and there followed an increased intellectual output. The rays were found to recreate the vitamin content in sterilized milk, and seeds so exposed showed increased fertility. Dr. Drury considered that the whole subject of dosage and skin reaction was paradoxical. It was, however, found that the best results followed when the rays caused a mild skin erythema. Eidinow had shown that the most economical way to use the radiation was to expose different parts of the body in turn, and then allow a period of rest to enable the skin to regain its normal sensitivity. Females usually reacted more than did males, blondes more than dark-complexioned people, and clear-skinned folk more than those with a greasy skin. Before subjecting patients to radiation their physical condition must be investigated. Mental patients had a better chance of recovery if their physical condition was good. There were three contraindicating states: agitated melancholics, acute maniacs, and epileptics; these patients not only did not benefit under the treatment, but they actually became worse. Simple melancholias, manic-depressives, and confused cases seemed to derive definite benefit from the treatment. Dr. Drury mentioned an interesting case of pellagra in a woman with mania. Severe terminal diarrhoea had set in, and there was very pronounced debility and wasting. The epidermis was brittle and shrunken, and the patient was nearly comatose. After four exposures to the radiation the diarrhoea had ceased, the skin was more supple, and the lesions less marked. A few days later she could stand unsupported and answered questions, but she suffered from heart disease, and died from this a few weeks later. Macroscopically there was seen to be some sclerosis of the white matter of the brain. Pellagra was a deficiency disease, and radiation had a definite power in restoring the deficiency. Dr. Drury referred to vitaglass, which allowed ultra-violet rays to pass freely, ordinary window glass cutting off most of these rays. He urged that careful records should be kept of all patients submitted to light treatments; these should include the weight, pulse, blood pressure, haemoglobin content, and the white cell differential count.

The PRESIDENT hoped the paper would provide a stimulus to other mental hospitals to set up similar installations. Horton Mental Hospital, Epsom, had the distinction of having been the first institution of the kind to adopt the treatment. Nearly all cases with chronic skin diseases and ulcers in the institution had been cured, and the large amount of time which had been spent in dressing these cases could now be devoted to other purposes. In the case of a nurse with a large tuberculous growth in the neck, an operation had been contemplated, but the light treatment in a short time had effected complete cure.

Dr. MUMFORD agreed as to the extraordinary improvement brought about in tuberculous conditions by artificial sunlight; it was also very useful in extensive lupus. Dr. DOVE CORMAC showed some patients who had derived benefit from the treatment, and one or two types in which it was not desirable to apply it. Dr. HASLAM FOX referred to the much better results obtained in young people as compared with adults.

RUPTURE AND INVERSION OF THE UTERUS.

AT a meeting of the Edinburgh Obstetrical Society on February 9th, the President, Professor R. W. JOHNSTONE, in the chair, Dr. FARQUHAR MURRAY (Newcastle) read a paper based on his own experiences of rupture and inversion of the uterus.

Dr. Murray objected to the terms "complete" and "incomplete" as applied to rupture, and suggested that they should be replaced by "intra-" and "extra-peritoneal" rupture. He thought that the chance of rupture of an old Caesarean section scar was greatly exaggerated, but this possibility should be kept in mind and the uterus in such a case be spared all possible stress at a subsequent confinement. During the last five years he had performed or had records of fifty repeat sections; in none was there evidence of imminent rupture, and though on occasions the scar area was thinner than the surrounding tissue, it was in all cases tough and firm. If a scar ruptured or became thinned out at a subsequent labour it was advised that the wound edges should be excised before resuture so that healthy muscle might be reached on both sides of the wound. The worst traumatic ruptures were considered to occur after versions performed when the uterus was tightly contracted and Bandl's ring greatly in evidence. To avoid such a risk perforation of the head followed by compression with the hand was recommended before a careful version was performed, so as to prevent the lower uterine segment being subjected to such a great strain. After a difficult version manual removal of the placenta was also preferable to diminish the risk of post-partum haemorrhage, but principally in order to explore the uterus thoroughly and so detect any rent in its wall. Dr. Murray was surprised at the degree of trauma of the cervix which was caused by spontaneous deliveries even when so premature as at the seventh month. Some of these lacerations spread up to the body of the uterus, causing repeated abortions and premature labours. As the extent of the tear could not be definitely determined from below, and dissection from the vagina was apt to imperil the ureter and might tear the uterine vessels, Dr. Murray described an abdominal operation for the efficient suture of the tear, which had proved satisfactory. Several cases of inversion of the uterus were described. Dr. Murray had difficulty in accepting the usual explanations of its etiology, as he had noted how difficult it was to cause inversion of the uterus directly with the hands in a Caesarean section and also how often a vigorous Credé method was practised without any untoward result. He thought that the arrangement of the uterine muscle played a definite part in the process, as in several Caesarean sections he had noticed that the thick part of the uterus was the centre, whereas the upper part of the uterus was nearly as thin as the lower uterine segment. It would be therefore quite easy for the thin portion to be pushed, pulled, or even be spontaneously invaginated and gripped by the thicker zone of muscle.

Hydatidiform Mole.

Dr. RALPH LODGE gave an account of thirty-seven cases of hydatidiform mole treated in the Royal Maternity Hospital or Royal Infirmary since 1922. A very large percentage of cases (70) occurred in the third decade of life, and only 8 per cent. after 40 years; 30 per cent. of the patients were primigravidae. The clinical features were principally those usually described, though a "brownish discharge" was frequently reported. Severe vomiting was common, and it was interesting to note that 50 per cent. of the patients had albumin in the urine. The Wassermann reaction was negative in all cases. As regards the after-history, nineteen patients had been followed up, and only one of these developed chorion-epithelioma. Dr. Lodge had investigated the records of the various pathological laboratories [illegible] had found that in this city and the [illegible] this disease was very rare, only six cases having been reported in nearly ten years. This being so, he thought that immediate curetting after expulsion of a mole should not be practised, since his statistics on treatment indicated that this operation was most frequently followed by a morbid convalescence. If any symptoms warranted curetting, and this were performed at a later date, the morbidity was not nearly so great. Statistics were given of the various methods of treatment, and the results of each were compared. It was found that the complications which were most common after expulsion were, first, sepsis (46 per cent. patients having a morbid convalescence); then haemorrhage (8 per cent. having severe loss of blood); and, next, development of chorion-epithelioma (one case), perforation of the uterus not occurring in the series. Vaginal hysterotomy proved to be a satisfactory operation, and abdominal hysterotomy was also very useful on occasions, especially when the uterus was as large as a full-time pregnancy.

PRIMARY CARCINOMA OF THE LUNG.

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland on February 11th, the President, Professor J. W. BIGGER, in the chair, Sir JAMES CRAIG reported a case of primary carcinoma of the lung in a man aged 51, and gave the following clinical details.

A pleural effusion had been tapped and about a pint of sanguineous fluid drawn off, which suggested an intrathoracic neoplasm. The face and ears were cyanosed, the upper thoracic region was oedematous with distended venules, and the arms and hands were swollen from oedema. There was no enlargement of liver, no ascites, and no oedema of feet or legs. A right pleural effusion was present. The patient had a dry cough, but no expectoration. The chest was tapped again, and 15 oz. of sanguineous fluid withdrawn. The dyspnoea increased and the patient died; two days before death he coughed up a quantity of foul-smelling pus, evidently from an abscess in the lung, although there had been no pyrexia at any time and no previous expectoration.

Dr. C. L. MCDONAGH exhibited lantern slides of skiagrams of the case which showed the pleural effusion, and, after aspiration, the lung abscess and tumour.

Dr. J. LAIT gave the following details of the necropsy findings.

Oedema of the upper part of the body was present; the pleural cavities contained much fluid and the pleura over the right lung was thickened. In the right lung was a large abscess, and a tumour was found involving the root of the lung. The pericardium was adherent and thickened; it contained numerous pea-shaped metastases, which did not involve the heart muscle. The tumour at the root of the lung surrounded and practically occluded the superior vena cava, where it entered the right auricle. The spleen contained a small secondary deposit in its anterior border. There were many retroperitoneal glands involved by the tumour spread, which had also invaded both suprarenals. No metastases were found in the bones nor in the other organs and viscera. The primary tumour in the lung and its metastases were found to be composed of solid masses of spheroidal carcinoma cells, supported by a fairly dense but variable stroma. Many cells showed vacuolation, apparently an attempt at secretion, and in places there was an appearance of glandular formation.

Dr. Lait said that in an advanced malignant tumour of this sort it was almost impossible to discover whether the origin of the cancer was from bronchial or alveolar epithelium. Microscopically he had identified the tumour growing in the lining of the bronchi, though the bronchi contained no tumour visible to the naked eye. The limitation of the tumour to the hilus of the lung, with but little diffuse invasion of the lung parenchyme, suggested a bronchial carcinoma, and he thought it had originated in the mucous glands of the bronchus. He discussed the tendency to classify all mediastinal tumours and lung tumours as either sarcoma or endothelioma, and mentioned the recent investigation made by J. B. Duguid of Manchester, who had re-examined a large number of mediastinal and lung tumours, and found that many labelled as sarcoma or endothelioma were really carcinomatous.

Diffuse Carcinoma of the Breast.

Dr. W. D. O'KELLY exhibited a specimen of diffuse mammary carcinoma removed from a young woman whose child was 18 months old. Nursing had been discontinued for over a year. The patient first felt a nodule in the breast, and soon after a clear, watery fluid was noticed coming from the nipple; this fluid later became milky, and was removed by the breast pump. The swelling was at first confined to one nodule of the breast, but later several distinct nodules were detectable. No glandular enlargement was observed in the axilla nor was any nodule found in the breast on the opposite side. On incising the breast the appearances resembled somewhat chronic interstitial mastitis, there being distinct fibrosis. In addition the organ was spotted over with creamy-white, rather cheesy-looking areas about one to three millimetres in diameter, the contents of which suggested caseation, but were rather too uniformly distributed for a tuberculous process. There was definite chronic interstitial mastitis, and cells filled the ducts and acini, many of which had broken down in places, thus producing pseudo-lumina. In some sections a rather cellular stroma, made up mainly of spindle cells, was a prominent feature. The basement membrane in general was intact, but mitotic figures were numerous, there being no difficulty in detecting at least one in every high-power field. The varying features found microscopically were suggestive of benign and of malignant processes, and fields could be readily found which were almost exactly like four or five plates in Ewing's *Neoplastic Diseases* illustrating the pre-cancerous stage in breast cancer. Dr. O'Kelly was satisfied, after a careful scrutiny of the breast, that the process was malignant, that malignancy was early and diffuse, and that the condition was one of diffuse carcinoma of the breast which he had not previously met with. Whether the diffusion was caused or accelerated by the pumping which took place it was impossible to say. The patient was under observation, and so far no recurrence had been recorded.

Appendicitis simulating Acute Yellow Atrophy.

Dr. A. R. PARSONS described a case which he believed at first to be one of acute yellow atrophy, but which at the necropsy proved to have been a case of appendicitis.

A man who had had influenza, and had almost recovered, became jaundiced a week later and mentally confused. The urine was dark and contained bile pigment. The patient did not complain of any definite pain, and the knee-jerks were absent; there was no history of syphilis. On admission his temperature was 99°, his pulse was fairly frequent, and he was wandering a little; during the night he became very restless. The next day his urine contained bile pigment, a little albumin, and the ammonium salts were greatly increased. He was very violent in the afternoon, and during the night became collapsed; he died the next morning, two days after admission, having only been ill for ten days. He had never vomited, and Dr. Parsons had considered that the diagnosis lay between uraemia and acute yellow atrophy.

Professor JOSEPH T. WIGHAM, demonstrating the specimens, said that the patient had died of appendicitis. There was fluid on the left side of the abdomen, and apparently a subphrenic abscess. It was interesting to note that the pus in the abdomen was on the left side, while the abscess was on the right. There was no abscess in the kidneys or spleen. He did not know the cause of the jaundice, but thought it was probably due to an almost complete necrosis of the kidney, somewhat similar to that found in acute yellow atrophy.

Cystic Growth in the Groin.

Dr. W. D. O'KELLY exhibited a tumour removed from the right inguinal region of a boy. A small, hard swelling had been noticed by the patient for about a year; it had begun to increase in size about a fortnight before admission. The swelling felt hard and elastic, and was considered to be a fibroma becoming malignant. At the operation it appeared to have a pedicle extending down towards the femoral sheath. On incision the mass proved to be cystic, with a thick, fibrous capsule in one side of which ran a fibrous cord somewhat suggestive of a vas deferens. The contents of the cyst were mainly a greenish, colloid substance, but one quadrant of the cavity was filled with a mass of fatty tissue suggestive of an epiplocele. Some haemorrhage had apparently occurred recently in this neighbourhood. The actual nature of the condition was not clear, but it seemed possible that it was a femoral hernia of which the neck had become occluded.

ULSTER MEDICAL SOCIETY.

At a meeting of the Ulster Medical Society held in the Pathology Laboratories of the Queen's University, Belfast, on February 24th, Dr. M. J. NOLAN, the President, in the chair, Professor FULLERTON exhibited a large collection of vesical and renal calculi, and of foreign bodies removed from the bladder. Dr. HICKEY showed microscopic slides of cocci obtained from the spinal fluid of a case of septic meningitis in a patient who recovered, and Sir THOMAS HOUSTON demonstrated the varieties of enterococci, explaining their clinical effects. Dr. R. HUNTER described some developmental anomalies. Mr. IRWIN showed a specimen of sarcoma of the collar-bone, a megalocolon, a hepatoma, etc. Dr. LEWIS demonstrated the stippling of red cells found in the administration of lead. Professor MACILWAINE described various electro-cardiograms. Dr. RANKIN, by means of diagrams, slides, and physical experiments, illustrated the histology of cancer. Dr. J. A. SMYTH showed sections of thyroid glands, indicating the difference between true exophthalmic goitre and toxic adenoma of the gland. Professor THOMSON exhibited the kidneys from a case of renal infantilism in a boy aged 14 years, and

specimens from a case of subacute bacterial endocarditis with infarcts in spleen and kidneys. Professor WILSON described a new medium for the isolation of typhoid bacilli and showed specimens. Professor SYMMERS discussed various specimens, including a hepatoma and an acute gastritis with much thickened and pus-infiltrated submucous coat. The PRESIDENT showed specimens of cor bovinum, a dissecting aneurysm, a matted ball found in the stomach, an aneurysm of the internal carotid in cavernous sinus, of hydronephrosis, a patent foramen ovale, and a rupture of the wall of the left ventricle.

DIAGNOSIS AND LOCALIZATION OF SPINAL TUMOURS.

AT a meeting of the Liverpool Medical Institution, on February 17th, Dr. HENRY COHEN read a paper on the diagnosis and localization of spinal tumours, based on sixteen observed cases.

Dr. Cohen discussed the diagnosis under three headings: the gradually increasing compression of the spinal nerves and cord, the site, and the nature of the compression. After a general survey of the clinical features he made special reference to their modifications according to the site of origin of the tumour and its relation to the cord, emphasizing the nature and mode of production of false localizing signs. The value of examining the cerebro-spinal fluid, and particularly of the combined cisternal and spinal puncture of Ayer, and the Queckenstedt phenomena, were discussed in detail. After dismissing the air replacement method of myelography as being of no practical value, Dr. Cohen related his experiences with heavy lipiodol introduced by the cisternal route. This was not without danger because of the irritation and comparative non-absorbability of the drug, which he had found present more than two years after injection. He considered that lipiodol should not be used until a definite diagnosis of compression of the cord had been made by careful clinical and cerebro-spinal fluid examination, or when exact localization was possible by clinical methods alone, or unless an operation was to be undertaken subsequently. Lantern slides were shown to illustrate the possibility of distinguishing extramedullary growths by lipiodol. The value of light lipiodol (ascendant) was questioned. After discussing the nature, pathology, and differential diagnosis of spinal tumours, Dr. Cohen indicated the general prognosis with regard to operative mortality, and the likelihood of recovery of function after complete removal of the tumour. He pleaded for the earlier recognition of these cases in order to improve the results in a disease which, when treated early, was one of surgery's greatest triumphs, but which, if left too late, resulted in the tragedy of a bedridden paraplegic.

The Blood Pressure in the Psychoneuroses.

Dr. S. BARTON HALL read a paper on the blood pressure in the psychoneuroses. After reviewing the literature concerned, he mentioned the importance of the part played by emotional physiology in psychopathology and psychotherapy. The precautions taken to exclude organic factors and the technique of the investigation were described. Blood-pressure records of 53 patients with neurasthenia and psychasthenia—30 males and 23 females—were shown. In 84.9 per cent. of the cases the blood pressure was found to be subnormal, as calculated according to Halls Dally's formula, while in 15.1 per cent. the systolic pressure was abnormally high. Cases from the series were described to illustrate the circulatory symptomatology in neurasthenia. Thirteen cases in which there was an abnormally high blood pressure were found to be associated with anxiety neurosis in some form, a distressing worry or fear continually dominating the patient's mind, and provoking continued anxiety and suppressed excitement. Tables and charts were shown demonstrating the return of the blood pressure to normal as the emotional condition responded to psychotherapy. It was suggested that the association between abnormally high blood pressure and states of increased emotional tone might throw some light on the etiology and treatment of hypertonus. Investigations had been made of 50 patients with a view to determining how far the first blood-pressure reading had been erroneous owing to emotional factors. Although every precaution had been taken to exclude emotional factors, in 43 of the 50 cases there had been shown to be a first reading higher than the actual blood pressure as ascertained a few minutes later; 35 cases showed a rise of 10 mm. of Hg or over, and 13 a rise of pressure beyond normal limits. The importance of error in highly strung individuals due to the emotional factor was emphasized, and the work of Cannon was referred to in the explanation of these phenomena. It would appear that the rise of pressure followed a sudden extraneous emotional stimulus acting directly through the sympathetic system, or indirectly by the sympathetic system on the suprarenal glands and thence transmitted to vasomotor nerves. In this way continued emotional strain might lead to frequent vaso-constriction and consequent thickening of the vessel walls.

AT a meeting of the Newport Medical Society, held at the Royal Gwent Hospital on February 23rd, with the President, Dr. P. C. P. INGRAM, in the chair, Dr. BEAMAN read a paper on the value of the fractional test meal in the diagnosis and treatment of gastric disorders. He said that the fractional test meal was now quite out of the experimental stage, and had become practically a routine procedure in the investigation of difficult gastric cases. He advocated it, not to replace the examination by x ray and bismuth meal, but as a valuable adjunct to this investigation. At times it gave help where x ray had failed to do so, and at others the confirmation of the x-ray indications clinched the diagnosis. Dr. Beaman described in detail the technique of the test, laying stress on the fact that the procedure involved very little distress to the patient. Immediate or early examination of the specimens was essential, for no reliance could be placed on an analysis of specimens left to stand for any length of time. Charts were shown of the normal type of curve and of the types of curve found in cases of duodenal and juxta-pyloric ulcer, in carcinoma and in achylia gastrica, and these were supplemented by a series of charts with short clinical notes of cases which Dr. Beaman had investigated, including examples of duodenal and juxta-pyloric ulcers, carcinoma, and hypochlorhydria. He strongly advocated the more frequent use of this method of diagnosis in all cases of difficulty where a gastric disorder was suspected.

AT a meeting of the West Kent Medico-Chirurgical Society on February 11th Mr. ZACHARY COPE gave an address on surgical emergencies in general practice, treating the subject under the four heads of: injuries; acute infections; stopped tubes; and rupture, ulceration, or displacement of viscera. He recommended for scalp wounds the application of gauze soaked in a solution of 1 in 1,000 acriflavine, after the removal of hair and cutting out the edges of the wound. If the case was seen within two hours it was possible to sew up the wound with fair prospect of healing. Eusol was also valuable in the treatment of such injuries. Doubtful sprains of the ankle frequently proved to be fractures, especially of the Pott's type; they should be treated by eversion and pressure over the painful spot. If the capsule of the shoulder was injured, gradual exercise and massage should be employed. Fracture of the scaphoid was always diagnosed wrongly as a sprain. In the case of cuts in the neighbourhood of the wrist, search should be made for any anaesthesia of the hand, since the median nerve was often severed. Fracture of the clavicle in a child should be treated by a simple sling, which was sufficient also for fracture of the surgical neck of the humerus when impacted. Dental plaster made good splints; it could be moulded by warm water, gave rigidity, and retained its shape. In the case of haemorrhage from the stomach, blood transfusion enabled life and strength to be preserved until an operation could be performed. Abscesses were often overlooked; it was inadvisable to wait for fluctuation, since the occurrence of a brawny oedema was sufficient indication. In retention of the urine due to enlarged prostate an enema should be given first; senile patients should not have hot baths. A soft rubber catheter should be tried first; if this failed a silk web catheter should be used.

Reviews.

THE SHIP SURGEON.

WE welcome the appearance of the third edition of the *Ship-Surgeon's Handbook*,[1] an eminently sane and practical work. Its author, Dr. VAVASOUR ELDER, can claim the widest experience of the subject of which he treats, and all medical men who are contemplating service on board ship as surgeons would do well to take this book as a guide to pilot them through the many difficulties which beset the doctor when engaged in medical practice on the high seas. Dr. Elder knows as well as anybody the limitations which surround the surgeon on board ship, and when he feels compelled to criticize existing conditions, he does it temperately and with a full knowledge that matters medical in a ship cannot always be adjusted with the ease that obtains on shore. Thus, much has been written of late concerning the space to be set aside for medical accommodation on board ship, and too often the mistake has been made of regarding what has been done on land as easy of accomplishment in a ship where limitation of space is the important governing factor. We have seen some suggestions concerning medical accommodation at sea which, if carried into effect, would go far to render the ship a non-paying proposition. A ship is the result of innumerable compromises, and if one department has to be enlarged it can only, owing to the limitation of space, be accomplished by encroaching on all other departments in the vessel. This Dr. Elder knows full well, and that is why his recommendations are so worthy of attention.

During the last twenty-five years a profound change for the better has come over medical work at sea. Ships are now so much better found in medical requirements, and the prospects of making a reasonable living have so improved, especially in large shipping companies, that life as a surgeon attached to a ship attracts an ever-increasing number of suitable men, and to-day there are many who have elected to follow the sea permanently. The value to a company of an able and experienced medical man cannot well be over-estimated; it takes some considerable time before the surgeon in a ship has mastered all the difficulties and can be accounted thoroughly experienced. Permanent service on the sea, of course, applies more particularly to the large mail lines, but even in smaller concerns, where surgeons serve for a voyage or two, the standard is now much higher, and while many apply, few are chosen. But to all who contemplate the service at sea as a surgeon, whether for a vogaye or two or permanently, this book of Dr. Elder's will be found to be an excellent guide to the life and duties of a medical man on board ship, and as such we commend it.

"BIRTH CONTROL."

THERE are few subjects to pronouncements on which temperament and the point of view seem to make more difference than that which is somewhat erroneously known as "birth control." Scientific calm has hitherto been conspicuously lacking in almost all such pronouncements, and those who advocate this control and the widespread knowledge of its details, and many of those who oppose them, are alike distinguished more by their zeal as crusaders or anticrusaders than by their accuracy as observers or logicians. At last, however, there has been published a collection of essays entitled *Medical Views on Birth Control*[2] by a number of medical men and women whose names carry weight not only with certain sections of the public but with the profession also.

The book is a symposium timely in its publication, interesting in its arrangement, level-headed in its statements, and helpful in its conclusions. The word "symposium" is used advisedly. By its etymology and its earlier usage it should connote a refreshing intellectual entertainment, the contributions to which, however serious their purpose, are of the nature of conversational exercises rather than of profound and exhaustive lectures. This is the character of the book, and it will thus be the more readily influential with the interested public and the less laborious to the busy medical practitioner. Though there is a certain unity in the general conclusion, the book yet represents, as is characteristic of its subject, different points of view. There are ten of them; for Sir THOMAS HORDER'S introduction or summing up may be held to present a definite aspect, and though the editor, Sir JAMES MARCHANT, secretary of the National Birth-rate Commission, himself writes nothing but the note, "Each contributor is alone responsible for his or her own contribution," his very assembling and presentation of this material may legitimately be held to constitute a point of view.

The main contributors are Dame Mary Scharlieb, Professor Leonard Hill, Sir Arthur Newsholme, Sir John Robertson, and Drs. H. Crichton Miller, Arthur E. Giles, R. C. Buist, and Letitia Fairfield. Perhaps the most suggestive of the eight essays are those by Dr. Crichton Miller, Professor Hill, Dr. Letitia Fairfield, and Sir Arthur Newsholme, but all contribute effectively. The mosaic of their argument may be briefly indicated. In a considerable number of cases there are definite medical indications for the prevention or control of conception, but each of these should be dealt with on its merits by doctor and patient in the consulting-room. Beyond this it is at least extremely doubtful whether a more general practice of control can be justified on any grounds, whether national, social, ethical, psychological, physiological, or any other. Most, if not all, such alleged grounds will be found to be based upon fallacies or on imperfect knowledge of facts, and to pay no regard to grave possibilities of injurious effects which the practice would admittedly entail. There are severe limitations to further marked reductions in the death rate; and there are conditions in Western civilized life which of themselves limit fertility and tend to its progressive reduction. With a lower birth rate it seems likely that within some twenty years the population of these islands may become stationary and then tend to decrease. There is, therefore, no danger of an accumulative over-population. There is no real evidence that generally in all the families in which no birth control by artificial means is practised there is an excessive proportion of children with undesirable or inferior qualities. In any state of life normality of inheritance is the rule. It is impracticable, except with a small proportion of mentally deficient individuals, to distinguish between inherent unfitness and unfitness acquired as the result of social and economic evils. There is therefore no reason for unduly pessimistic views as to the present differential birth rate, such as it is. There is no valid evidence that the average woman is worn out by having a large family. Such families have, in decent homes, many advantages, and benefit not only the individual children but the parents in later life. No sympathy is needed for them, except in the case of the thriftless, and the remedy for this last class is clearly something other than conceptual control. Normal sex relations between husband and wife are not merely the gratification of animal appetite, but are, or should be, a perfectly definite factor contributing to adjustment on every plane—physical, mental, and emotional. The urge for parenthood can, with many, be replaced easily enough, but only in youth: in most people it refuses to be repressed later. It outlasts procreative power and is too potent a biological force to be lightly thwarted. Physiologically and psychologically such thwarting leads to dire results. Freedom for sex relations without fear of undesired consequences, like some other so-called freedoms, leads directly to a loosening of moral behaviour, not only in the married but in the unmarried. Finally, in analogy with the case of the mayor of a French provincial town who, summoned before his king to account for the bells not having been rung on the occasion of the royal visit, gave as his twenty-seventh reason that there were no bells, not one of the prescribed means of "birth control,"

other than reasonable abstinence, can be relied upon to effect even its immediate object.

The book under review can confidently be recommended to all those, medical or lay, who wish to be acquainted with the facts on which these arguments are based, and to be helped to form a reasonable opinion upon a very difficult and important subject.

MENTAL DISORDERS.

THE fifth edition of Dr. STODDART's well known textbook on *Mind and its Disorders*,[3] whilst retaining all the features characteristic of its predecessors, includes a good deal of new matter relating to recent modes of treatment and research. In the section devoted to general paralysis an account is given of the malarial treatment of this disease, and mention is also made of tryparsamide therapy. The description of the methods of intrathecal medication which appeared in former editions has been omitted from this edition as this form of treatment has now been generally abandoned. In a short chapter on encephalitis lethargica and its mental sequelae, Dr. Stoddart recommends the administration of hexamine, not only in the acute stage, but also during the sequelae when presumably infection still persists. For the Parkinsonian rigidity he advises hyoscine *in full doses*.

Dr. Stoddart is an enthusiastic disciple of Freud, and his chapters abound in explanations of symptoms in the terms of Freudian psychology. His partiality to this school of thought has not, however, caused him to neglect to mention other methods of research into mental processes or to give them their due value. His approach to the study of psychiatry from so many different directions may at first lead to some bewilderment, but to the experienced student and to the practitioner it affords a breadth of view not otherwise obtainable, and may so lead to further study and research.

The descriptions of the various psychoses under their respective headings is wellnigh complete. The consideration of pellagra, however, is relegated to the chapter on cutaneous affections. It would seem desirable that in future editions the author should devote more space to this now increasingly recognized disease. Dr. Stoddart is again to be congratulated on a comprehensive and challenging textbook.

IONIZATION IN EYE DISEASES.

DR. A. CANTONNET, the ophthalmologist of l'Hôpital Beaujon, has written a little book[4] giving the result of his experiences of ionization in the treatment of eye diseases. After noting the work of others, and giving an account of his methods, he describes his cases. His mode of application was by a tube electrode. This tube carried at one end an eye-bath, at the other a carbon electrode connected with the battery; the interior of the tube was filled with the electrolyte; the circuit was completed by a plate on the nape. A variety of drugs was used, but chiefly iodides and salicylates. In all he treated 412 cases. At the conclusion he asks himself whether this mode of treatment is a step in advance or whether it may be an illusion. His conclusion is that it is a most interesting form of treatment, and that to neglect it is to suffer loss. He is very frank in relating his results. Each case is recorded separately and in detail, and there is a summary of the whole according to condition. Scars of the cornea which are superficial show more amelioration than interstitial scars. Scars of the skin of the lids give "very beautiful results," but pterygion and symblepharon none. Episcleritis and scleritis were rapidly relieved. Iritis was benefited to some extent. Cataractous opacities of the lenses and vitreous changes showed no benefit, nor did glaucoma when absolute, but there were reactions of interest in acute, subacute, and chronic; retinal and choroidal lesions were unaffected. Ulcers of the cornea, with and without hypopyon, gave variable effects, phlyctens for the most part none. He has as yet not treated cases of conjunctivitis by the method.

RADIOGRAPHY OF THE HEART.

MUCH the best recent work on the radiology of the heart and the vessels at the base of the heart has come from the French. The latest essay on this very interesting subject, by Dr. MANOEL DE ABREU, is entitled *Essai sur une Nouvelle Radiologie Vasculaire*[5]; it follows upon, and adds to, the valuable work done by Cerné, Mougeot, Thoyer-Rozet, Delherm, Chaperon, Vaquez and Bordet. We have nothing but praise for it, and no radiologist can afford to be unacquainted with it.

The volume is beautifully printed and illustrated; it is altogether a somewhat remarkable publication—one of those books which it is a joy to read and a joy to look at. In the introduction the author says that the affections of the mediastinum, owing to their situation and *inaccessibility*, belong almost entirely to the radiologist. This is quite true, but—and it is a very big but—the radiologist must at the same time be an anatomist and a cardiac specialist, and it is only when he combines these three qualities that he can successfully interpret the radiological shadows. Photographs, drawings, radiographs, all go to illustrate this exceptional monograph, and the author has so arranged them than in most instances the three go together and illustrate and explain one another. A great number of the radiographs are long-distance ones, "teleradiographs," and all the exact measurements are made from these. A very interesting point is thus brought out, for it is clearly demonstrated that a very small alteration of angle in the position of the patient under examination—that is, whether in an oblique position the angle is, *say*, 15 or 40 degrees—will make an enormous difference in the measurements of the aortic shadow—indeed, practically double it. It follows from this that extreme accuracy in angulation of the patient is of essential importance in the measurement and the interpretation of the breadth of the shadow cast by the aorta or the aortic arch.

Apart from Knox's work on the heart, this subject has received very little attention from British radiologists. Groedel of Germany, in the early days, did a considerable amount of pioneer work, especially from the point of view of the orthodiagraph. To the French school is to be assigned pre-eminence as regards elucidation of radiological appearances in this special branch of work; this newest monograph on the subject is by no means the least interesting and valuable of the many communications on the subject emanating from Paris.

MASSAGE AND REMEDIAL EXERCISES.

THE second volume of Dr. KIRCHBERG's manual on massage,[6] the first volume of which was reviewed in our issue of September 25th last, deals with massage and remedial manipulations and exercises in the treatment of diseases of individual organs and systems, and covers a wide field. The first part is concerned with massage in the treatment of affections of the circulatory, the digestive, and the respiratory systems, massage in cases of obesity, and mechano-therapy in gouty subjects. Massage in diseases of the genito-urinary organs is the subject of the second part; the third deals with diseases of the nervous system; the fourth with affections and injuries of the limbs; the fifth with the importance of massage and exercises for women in health, during pregnancy, and in childbirth, and in the treatment of affections of the female organs of generation; the sixth with affections of the auditory apparatus; and the seventh and final part with massage of the mucous membrane of the upper air passages. The

[5] *Essai sur une Nouvelle Radiologie Vasculaire.* Par Manoel de Abreu. Paris: Masson et Cie. 1926. (Med. 8vo, pp. 215; 58 figures, 27 plates, 38 fr. sans majoration.)

[6] *Handbuch der Massage und Heilgymnastik.* Band II. Von Dr. med. Franz Kirchberg. Leipzig: Georg Thieme. 1926. (Sup. roy. 8vo, pp. viii + 334; 23 figures. M.15; bound M.17.)

first three parts, and the greater part of the fourth, are written by Dr. Kirchberg. himself. In a section dealing with the treatment of fractures and dislocations Dr. Koch of Bochum collaborates, as also does Dr. W. Seele in a section on medico-mechanical treatment of fractures. The part on female affections and disorders is by Professor Koblank of Berlin; that on massage of the auditory apparatus by Professor Grossmann; and on massage of the upper air passages by Dr. Echtermeyer.

The volume as a whole constitutes a manual of great value and importance. It is clearly written, does not push massage and remedial exercises to the exclusion of other therapeutic agents, and gives notes of warning of injuries that may be caused by ignorant or careless uses of massage, especially in the case of young women. As compared with the first volume there are very few illustrations, seventeen out of the twenty-three being skiagrams of fractures or dislocations. The first volume must consequently be consulted for information regarding the technique of the various manipulations. In other respects this second volume is a compendium of information on the subjects with which it deals, and reaches a high level of medical literature. There is a good index of subjects and authorities at the end of the volume, and a bibliography at the end of each of the parts.

NOTES ON BOOKS.

X-Ray Apparatus, its Arrangement and Use,[7] is the title of a small book by Mr. P. K. BOWES, M.A., B.Sc., honorary radiographer to the Kent and Canterbury Hospital. It has been written to help those studying for the various examinations for radiographers, and deals, very simply, with electricity, transformers and induction coils, the x-ray tube, the nature of x rays, photography, and so on. On the whole it is practical and useful within its limitations. The author sets out to say a thing simply, and gives much information of a very practical kind in language which can be easily understood. There are some ninety illustrations, all of which are well chosen, and help to make the text more easily understood. The book should be useful to lay radiographers and to nurses and assistants in the x-ray department.

A small book of some fifty pages by Dr. W. ANNANDALE TROUP deals with the *Ultra-Violet Rays in General Practice*.[8] The author writes with an experience of about eighteen months, and is rather boisterous in his enthusiasm. He outlines first the history of the subject from Herodotus, Cicero, and Pliny to the more scientific advocates of to-day; then follows a short general survey of the action of light on the living organism, and some general considerations for eight pages. Technique is dealt with in a chapter of eighteen pages, and is illustrated by photographs of various types of lamps. The remaining twenty-one pages are devoted to a consideration of the therapeutic application of ultra-violet rays upon the tissues, with reports of successes. Various skin conditions, such as eczema, herpes, alopecia, lupus, acne, and psoriasis, are mentioned in short, terse sentences; cure is to be expected apparently in all, or at any rate in the great majority. This is followed by paragraphs on the blood, on the cardio-vascular effects, disorders of nutrition and of the alimentary system, neurasthenia, paralysis agitans, the respiratory system, chronic nephritis, and sprains—a truly striking variety of pathological conditions amenable to this treatment. It is claimed that alopecia is readily cured in from twelve to eighteen treatments, that three or four exposures terminate early cases of ringworm, that psoriasis invariably yields to the rays, that in herpes zoster the vesicles dry up in a week without intercostal neuralgia, that in pertussis the whoop stops after three or four applications, and that in eczema the itching is always removed, cure resulting in the majority of cases. According to the author, "the above are only a few of the conditions which can be relieved by this and not by other forms of treatment," but he finds it necessary to add that "the treatment is not a cure-all."

The sixth edition of *Lessons on Massage*,[9] by MARGARET D. PALMER, has been revised by Dr. DOROTHY WOOD, who has found it necessary to rewrite the massage section owing to the changes and advance in massage methods since the war. The first two chapters now deal with the history and theory of massage, and these are followed by eleven chapters in which the morbid conditions of the various organs and systems are considered separately, special attention being given to the indications for massage and to the explanation of its specific effects in each case. The chapters in the previous editions which dealt with bandaging, Swedish remedial gymnastics, and the tables of gymnastic exercises have been omitted as being inadequate for modern requirements. The anatomy section, consisting of eight chapters, is now placed at the end of the book for reference. This revision has considerably improved a deservedly popular handbook.

PREPARATIONS AND APPLIANCES.

Eustachian Sound.

MR. F. PEARCE STURM, M.Ch., aural surgeon, Leigh Infirmary, Lancashire, has devised a graduated carrier and flexible Eustachian sound of stainless steel. The stem of the carrier, divided into three divisions of 12 mm. each, is the length of the adult Eustachian tube. The position of the graduation marks with regard to the Eustachian catheter indicates the depth to which the sound has penetrated the Eustachian tube. When introduced, for example, as far as the second division (24 mm.) the bulbous end of the sound is at the isthmus tubae, the commonest position of a stricture. These metal sounds will open Eustachian tubes in cases where the more flexible gum-elastic bougie bends back and reappears in the pharynx. They make it possible to introduce a Weber Leil's inner catheter beyond obstructions otherwise impassable, and have proved very satisfactory during the several months in which they have been in daily use. They are made by Messrs. A. Charles King, Ltd., 34, Devonshire Street, London, W.1.

SCHOLARSHIPS AND GRANTS IN AID OF SCIENTIFIC RESEARCH.

SCHOLARSHIPS.

THE Council of the British Medical Association is prepared to receive applications for Research Scholarships, as follows:

A Scholarship, known as the ERNEST HART MEMORIAL SCHOLARSHIP, of the annual value of not more than £200, and three other RESEARCH SCHOLARSHIPS, each of the annual value of not more than £150, for research in any subject (including State Medicine) relating to the Causation, Prevention, or Treatment of Disease.

Each Scholarship is tenable for one year, commencing on October 1st, 1927. A Scholar may be reappointed for not more than two additional terms. *A Scholar may hold a junior appointment at a University, Medical School, or Hospital* provided the duties of such appointment do not interfere with his work as a Scholar.

The conditions of the award of Scholarships are stated in the Regulations, a copy of which will be supplied on application to the Medical Secretary of the Association, British Medical Association House, Tavistock Square, London, W.C.1.

GRANTS.

The Council of the British Medical Association is also prepared to receive applications for Grants for the assistance of research into the Causation, Treatment, or Prevention of Disease. Preference will be given, other things being equal, to members of the medical profession and to applicants who propose as subjects of investigation problems directly related to practical medicine.

The conditions of the award of Grants are stated in the Regulations, a copy of which will be supplied on application to the Medical Secretary of the Association, British Medical Association House, Tavistock Square, London, W.C.1.

Applications.

Applications for Scholarships and Grants for the year 1927–28 *must be made not later than Saturday, June 4th, 1927*, on the prescribed form, a copy of which will be supplied by the Medical Secretary on application. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated to whom reference may be made.

ALFRED COX, *Medical Secretary.*

March 5th, 1927.

Nova et Vetera.

PETER GOLDMAN'S DESCRIPTION OF THE DESOLATION OF DUNDEE.

Inficiunt maculae pectus, sensusque labescunt,
Mens animi languet, tingit rubor igneus ora.

[Spots stain his breast, the giddy senses slip,
His mind grows weak, the face all red with heat.]

THESE lines, in which Peter Goldman describes the illness of his brother John, victim of the pest in 1607, contain a vivid picture of a case of typhus, as distinct from bubonic plague. Recognition of the importance of the spots, which is still emphasized in the German term *Flecktyphus*, seems to have begun here in the seventeenth century. An early instance of the term "spotted fever" is found in a letter of 1624, where the writer says:

"We had 328 died this week, a greater number than hath been these fifteen or sixteen years, and yet no mention of plague. . . . But this spotted fever is cousin-german to it at least, and makes as quick a riddance almost."—BIRCH, *The Court and Times of James I.*

Fracastorius in Italy had described a petechial fever a century earlier, but the description includes intestinal symptoms suggestive of the enteric group.

A chart published in the BRITISH MEDICAL JOURNAL in 1895 (vol. ii, p. 254) shows that in the nineteenth century typhus fever was constantly present in Dundee, and that it only began to lessen after the clearance of congested areas had been started in 1870. Before that date it was subject to epidemic prevalence, and so late as 1865-66 the cases treated in Dundee Royal Infirmary rose to 1,084, the population being about 100,000. Under modern sanitary methods typhus has now disappeared, but while it was prevalent the history in Dundee was congruent with the general state of our knowledge of the disease. At one time prior to the recognition of the enteric fevers as specific the medical staff made a report, not entirely harmonious, on the question whether fever cases should be treated in the ordinary wards. Evidence had been collected from all over the country, and this, read in the light of subsequent knowledge, shows that different towns had to deal mostly with one or other of the two specific groups, and that those in the enteric areas thought that cases could be treated in the ordinary wards, while those in typhus areas knew that they should not. The civil desolation produced by epidemics is delineated in the *Delitiae Poetarum Scotorum* (1637) by two of the writers—Hercules Rollok, elder brother of the first principal of Edinburgh University, describes the plague in Edinburgh in 1585, and Peter Goldman that in Dundee in 1607.

Peter Goldman, a junior among the seven sons of James Goldman, merchant, was born in 1587, and entered St. Salvador's College, St. Andrews, in 1601. On his father's tombstone of 1605 he, alone of the seven sons, was termed "Mr.," so that he probably graduated. On December 7th, 1609, he entered Leyden University, where he graduated M.D. on July 26th, 1610. In 1617 he presented complimentary Latin verses on the occasion of King James's visit to Dundee, and an entry of date November 7th, 1621, in the Compt Buik (Scot. Hist. Soc.) of David Wedderburn, merchant, which reads, "Lent Doctor Goldman 4 buikis Iliades Homeri ane uther Greik buik," is the latest item in the personal tale of Mr. Peter so far as it has been accessible to me. In Leyden his name is the first of the series of Scottish medical students who, especially in the time of Boerhaave nearly a century later, frequented and graduated in that university.

Within eight years after the death of James Goldman four of the older sons met with more or less sudden death. Patrick was drowned off the coast of Holland; John died of pest; Robert was thrown from his horse and, falling on his sword, "omnes abrupit renum violento vulnere venas," and William, aged 43, died apparently from apoplexy at the height of his civil activities. Peter wrote a long Latin poem with the title "Margaretae Iacchae matris suae . . . Lachrymae," from which is translated this account of the plague.

"A plague, by fault of air or sprung from earth,
Lay on the walls to which Tay gives a name. [Taodunum.]
Here for two years the loathsome thing ran wild,
Wasting the homes, scanting the town of folk:
Promiscuous funerals crowded, old and young;
All round were grief and signs of horrid death.
Youth breathed its soul before the parent's eye,
And at Life's threshold childhood laid its life.
Medicine gave way beneath the weight of ill;
Apollo-taught Kinloch[1] could only sit
And pray the Fates to bring the better time.
Vain, flame to purge the house, water the frame;
Vain to use wine against disease's bane;
Vain to drum prayers upon unhearing ear,
Contagion spread still more on spreading more.
Now Ramsay died, now just and ever true
Lovell and Lindsay fell, whose care was aye
To make the people's weal their highest law.
Now tombs ran short, the cemet'ry o'erflowed;
Handbell unrung, the funeral order failed
To keep the customed way's sad company.
One way alone seemed counsel in despair,
Abandoning home to flee the baleful air:
Dwellers were few, rare guardian at the gate,
Thistles were found at crosses once foot-smoothed
And thorny burdocks mid in pavèd streets.
A piteous crowd, staking in neighbouring fields,
Fixed roofs or peltclad fled the painful shower.
Some villas sought or widespread neighbour towns,
And John of ours with his too faithful wife
For shelter fled to Winton's castled tower;
But weird of pressing ill and future grief
Its door gaped blue with gold all bordered round
And, wound itself, foreshowed wound to its lord.
What profits man to leave his sweet abode;
Fate follows faster than the wind or cloud.
Spots stain his breast, the giddy senses slip,
His mind grows weak, the face all red with heat.
Quick came his wife, delight of life, unstayed
By prayer of friend or her protesting kin;
Embracing still the racked frame of her spouse,
She, raising eyes, cried 'Fate will try in vain
To take me from my love. With him I'll die;
Without him I'ld not live; Nor fire nor flood,
Nor tyrant Jove himself shall part us now.'"

The poor lady had her wish, and their tombstone reads: "Heir lyes john goldman, mairchand, and elisabeth Traill his spous, quha both depairtit in september 1607, of his age 34, hirs 29." The less picturesque verses of Rollok add the gruesome detail that the sexton by night dragged the dead away with a hook and threw them in a fetid trench. The special hooks for this are still to be seen in museums—for example, at Marseilles.

R. C. B.

DANGEROUS DRUGS REGULATIONS, 1926.

MEDICAL TRIBUNALS.

THE Home Secretary gives notice that, in pursuance of the Dangerous Drugs Regulations, 1926, he has appointed two medical tribunals—one for England and Wales, and one for Scotland—to which, as occasion arises, may be referred for examination and consideration any case in which there is, in his opinion, reason to think that a medical practitioner may be supplying, administering, or prescribing any of the drugs to which the Dangerous Drugs Regulations apply, either to or for himself or to or for other persons, otherwise than as required for purposes of medical treatment.

The appointment of these tribunals was recommended by the Departmental Committee on Morphine and Heroin Addiction, presided over by Sir Humphry Rolleston, which reported in January, 1926. The tribunals are constituted as follows:

England and Wales.

Sir Humphry Rolleston, Bt., K.C.B., M.D., F.R.C.P. (Chairman), nominated by the General Medical Council; Sir William Hale-White, K.B.E., M.D., F.R.C.P., nominated by the Royal College of Physicians of London; and Dr. John Wardle Bone, M.B., C.M., B.Sc., nominated by the British Medical Association, with Mr. E. W. Hansell, M.A., Recorder of Maidstone, as legal assessor.

Scotland.

Sir Robert Philip, M.D., F.R.C.P.Ed. (Chairman), nominated by the Royal College of Physicians of Edinburgh; Dr. Ashley Watson Mackintosh, M.D., F.R.C.P.Ed., nominated by the General Medical Council; and Professor Thomas Kirkpatrick Monro, M.D., F.R.F.P.S.Glasg., nominated by the British Medical Association, with Mr. John Cowan, K.C., as legal assessor.

Substitute members have also been appointed for each tribunal to act in the event of the original members being unable to do so.

British Medical Journal.

SATURDAY, MARCH 12TH, 1927.

PATENTED RESEARCH.

IT was with no little surprise that we learnt that a body calling itself the Scarlet Fever Committee is taking out a patent covering the results of the researches made by Dr. George Dick and his wife into the prevention and treatment of scarlet fever, which have been frequently referred to in this JOURNAL. The step is so unusual in medical science that it naturally calls for comment. If our readers will refer to the report of a lecture by Dr. Gardner Robb in our issue of January 2nd, 1926 (p. 11), they will find an account of the work that has been done in recent years in connexion with scarlet fever. The first significant observation seems to have been made in 1917 by Schultz and Charlton; they discovered that when the serum of patients convalescent from scarlet fever was injected into the skin of acute cases showing a well marked rash, a bleaching of the rash occurred in a small area around the site of injection. This reaction is now known as Schultz's test. Somewhat later a method of differentiating the biological types of haemolytic streptococci was worked out by Dochez, Avery, and Lancefield. In 1923 Dr. Dick succeeded in obtaining a pure culture of a haemolytic streptococcus from a case of scarlet fever, reproduced the disease in a volunteer by applying a swab of the culture to the throat, and concluded that this streptococcus was the specific agent in scarlet fever. In 1924 the same observer demonstrated that a Berkefeld filtrate of the media in which the specific streptococcus had been grown contained a toxin which, when injected intradermically in cases of scarlet fever, produced a reaction (now known as the Dick test) similar to the Schick reaction in diphtheria. In the same year Dochez of New York prepared, by a special method, an antitoxic serum in the horse, which, in the hands of Blake, Frask, and Lynch, gave very good results in treatment; and Dr. Dick reported that he had, by a different method, prepared an effective antitoxic horse serum. Recently Messrs. Parke, Davis and Co. have put on the market a serum which is claimed to be both antitoxic and antibacterial. Such are the important results that science has gleaned from the labours of this band of workers.

It appears that, so far as his share of the work is concerned, Dr. Dick proposes to take out a patent, both in America and in this country, for the process of isolating haemolytic streptococci specific for scarlet fever; growing them, obtaining toxin therefrom, and antitoxin specific to scarlet fever; for the process of identifying and standardizing the antitoxin; for the method of using the human skin for tests; and for other connected processes. What motives have actuated Dr. Dick and his friends to take this step it is not our business to inquire; we confine our remarks to what we conceive to be the opinion of the medical profession upon the general question. Perhaps the principal objection that can be raised against the practice of patenting is that it will commercialize research. Naturally, this observation does not apply to all medical discoveries; most of the steps that lead up to a directly profitable discovery would be rejected as commercially unworkable by the financial agent. The usual course is as follows: A disease is on general grounds suspected to be of microbial origin; a number of micro-organisms are incriminated; defensive bodies are shown to be produced; the offending microbe is run to earth, but the existence of biological varieties confuses the issue; these have to be differentiated, and so forth. None of these essential discoveries would be touched by the financial agent; he waits for the observer who places the coping-stone to the edifice, and then helps to patent the whole, hoping to make a substantial profit; it would be difficult to estimate the market value of a patent of the antiseptic method. Now there can be no question that a man is entitled to be paid for work done, even if it is merely placing the coping-stone; and money making is one of the most harmless of occupations, as Dr. Johnson has told us. But we are here dealing with a special type of work—work which displays the quality of originality. Ordinary work, in which originality has no part, rightly demands full payment, with one exception—namely, work done for charity; in the latter case the satisfaction experienced by the doer and the gratitude (if any) of the recipient constitute a sufficient reward. We imagine that with many, if not most, of the original workers in medical science an attitude somewhat similar to the latter is taken with regard to their discoveries. They make a distinction between the perfectly legitimate protection of an original literary work of art by copyright and the patenting of a discovery which lends itself directly to the alleviation of human suffering. To restrain by any means the free currency of such a discovery, to hinder in the smallest degree the application of it in helping to lift the burden of human suffering, or in the promotion of further research, would be impossible to them; to ask money for it would be revolting in the extreme. They have, in fact, their full and sufficient reward. We may recall here the sentiment expressed by the late Lord Lister shortly before his death, on the occasion of the presentation of a casket to him: he needed no other reward than the consciousness of having benefited humanity, or words to that effect.

There is another numerous class of research workers who, while fully alive to the sentiments we have described, are more directly actuated by curiosity and the interest they feel in discovery for its own sake. They regard themselves and the rest of the world's scientific workers as belonging to the same team and, as it were, playing the same game. To them any co-worker who is seeking his own profit, keeping any of his work in the background for his own advantage, hindering others from taking full advantage of his work—in short, not working loyally with the team or playing the game—to them such a character has an unsavoury aspect. The reward which this true type of worker obtains is the satisfaction that the anticipation and making of a discovery afford, and the honour he receives from his fellows.

There remain the small—but, it is said, increasing—minority of research workers who regard money making as an essential part of their work. Some of them doubtless consider that no justification is required for that attitude. We do not believe they

have the approbation of the best spirits in the profession. Others may argue that the taking out of a patent is desirable in certain circumstances, in order to restrain the injudicious use of an agent imperfectly prepared. It would seem, however, that if the processes are fully and accurately described there can be no more danger from their employment in the hands of other competent workers than in those of the discoverer. Again, it may be said that patenting is justifiable in order to raise funds sufficient to carry out the costly methods of modern research. It is difficult to believe that there is much point in this argument, for it is notorious that in recent years the outpouring of dollars in aid of research has been phenomenal—so much so that some authorities have gone so far as to suggest that these praiseworthy efforts have been overdone, and that the results have been less visible in the furtherance of science than in the multiplication of posts.

To many it may seem that, considering the infrequency of the practice of patenting medical discoveries, the matter may be safely ignored. Apart from the fact that the frequency is showing decided signs of increase, there is a serious fallacy in this argument. That the cases are at present few is of no importance; if the practice is adopted at all, and if it is recognized as legitimate by the profession, it will be apt to become general. Research workers would need to take out patents for their own protection; otherwise, if they were to publish their results in the course of their observations, some trifling modification of method could be used to justify the taking out of a patent against them. The practice, once allowed on the part of a few, would, like poison-gas, have to be adopted by all in spite of themselves. Finally, it may be argued that, even if allowed, the practice of patenting could not be detrimental in any way to the progress of science. As to this we have the means of judging by inquiring what has happened in cases where it has been adopted.

It is not always easy to stamp out objectionable practices, but in the present case it is probable that an unreserved expression on the part of the medical profession of its opinion on the ethical aspect of the question would prove sufficient.

THE RHEUMATIC CHILD.

THE toll of premature deaths from rheumatic heart disease has led to the institution of campaigns in this country and America to diminish the incidence of rheumatic infection. In England and Wales 30,000 unfimely deaths annually are estimated to be due to this cause, and whereas the death rate from tuberculosis has fallen since 1918, that of rheumatic heart disease has risen. In 1924 the Ministry of Health investigated the incidence of the rheumatic diseases, including rheumatic fever as well as rheumatoid disease,[1] and in July last a special subcommittee of the Science Committee of the British Medical Association published a report (to which the SUPPLEMENT for July 3rd, 1926, was devoted) on rheumatic heart disease in children, dealing with its environmental and other predisposing causes, the effect of tonsillectomy, and the organized after-care of rheumatic children in Great Britain. This report recognized the etiological importance of damp buildings, the beneficial effect of tonsillectomy, and the need for institutional treatment of rheumatic infection in every large city. The Medical Research Council has now published a report by its London Committee on Ante-Natal and Post-Natal Problems of Child Life on "Social Conditions and Acute Rheumatism,"[2] which, indeed, contains more than its title might lead the reader to expect. This committee's report begins with an introduction by the chairman, Dr. G. F. Still, who also provides a final summary of the conclusions. The chief object of the investigations was to throw light on the etiology, apart from the nature of the specific agent, of the special incidence of acute rheumatism among children of the hospital class; a noteworthy feature is the trouble that has been taken to obtain controls, and in this connexion the inclusion of Dr. John Brownlee in the committee is a guarantee of sure guidance in the difficulties and fallacies inherent in statistical inquiries. The data obtained were in the first place the medical and social histories of 721 families containing one or more rheumatic children, obtained at the Hospital for Sick Children, Great Ormond Street, and St. Thomas's Hospital, London, and the Royal Hospital for Sick Children, Glasgow; allowance was thus made for variations in the local conditions, such as the nature of the soil and dampness. As controls with these "rheumatic families" the histories were taken of 200 families each containing a non-rheumatic child under hospital treatment, divided equally between London and Glasgow. In addition, the histories of 1,872 children resident in the various Poor Law institutions were analysed.

A comparison of 700 consecutive well-to-do children seen in private practice, giving an incidence of 0.7 per cent. of rheumatism, with 1,000 consecutive children seen in the out-patient department of King's College Hospital, with rheumatism in 13 per cent., confirmed the general impression, of which previously there did not appear to be any statistical proof, that acute rheumatic infection is much commoner in the hospital group. It is, however, clearly shown that the incidence of rheumatism among the hospital class is not in direct relation to the degree of poverty, for if the hospital patients are divided into three grades according to their financial position the poorest of the three shows a lower incidence of rheumatism than the other two. Hence the influence of poverty would appear to depend rather on some associated condition, and of the various possibilities explored maternal care with regard to clothing and exposure to cold and damp seemed to be a conceivable factor. Exhaustive consideration of the question of heredity, accompanied by eight pages of the family trees for three generations, shows that the general picture of the family histories is that of rheumatism attacking several members of one generation rather than of its transmission from one generation to another. From analysis of the data referring to the incidence of rheumatism in relation to the colour of the hair and eyes, it appears that the darker types tend to show a greater predisposition to rheumatism—a conclusion directly opposite to Dr. Shrubsall's results in 1903.

The possibility of transmission of infection from cases of rheumatism is fully discussed; the instances of the disease arising in children sharing the same bed as rheumatic patients are carefully analysed; and the comparative immunity of children resident in Poor Law institutions is mentioned as having a possible bearing on the transmission of rheumatism. On the whole the data collected do not justify any conclusive evidence of contagion, though many of them are consistent

[1] Report on Public Health and Medical Subjects, No. 23.

[2] *Child Life Investigations: Social Conditions and Acute Rheumatism.* Special Report Series No. 114, Privy Council, Medical Research Council. London: H.M. Stationery Office. 1927. (Pp. 103. 2s. 6d.)

with this view. The relation of the state of the tonsils to rheumatism and the influence of tonsillectomy in preventing its occurrence and recurrence have been much discussed in recent years, and it is interesting to gather the deductions from this open-minded analysis of carefully collected data. Statistical evidence confirms the association between tonsillar and rheumatic disease; but an unhealthy state of the tonsils is clearly not an essential factor, for in 25 per cent. of rheumatic children the tonsils are apparently healthy. Neither cutting nor enucleation of the tonsils guaranteed immunity from rheumatism, for out of 295 rheumatic children whose tonsils had been surgically treated 129, or 43.7 per cent., had their first rheumatic attack subsequently. Dampness of the dwelling-house has generally been regarded as playing an important part in the production of acute rheumatism, and it may come as a surprise to some observers to be told that this investigation lends little support to that view.

The philosophical and entirely unbiased manner in which these investigations have been carried out must impress the reader, and perhaps shake some convictions which have been formed as the result of current impressions and expressed opinions. In particular there may be some disappointment at Dr. Still's conclusion that the inquiry has not given any decisive indication as to the means which should be adopted for the prevention of rheumatism. The most hopeful line is improvement of the environmental conditions of the poor so that they approximate to those in institutions where rheumatism is less common. Some help in elucidating the way in which rheumatism spreads might result from notification of the disease, for its prevalence and distribution could thus be more accurately estimated and plotted out; but compulsory notification would probably present administrative difficulties. Even if it were established, the diagnosis of the more characteristic manifestations of acute rheumatism—namely, cardiac lesions and chorea—is by no means free from the risk of possible mistakes, and in its less definite forms rheumatism may be difficult to diagnose. It is uncertain what proportion of rheumatic children are left with damaged hearts: some hospital figures have placed it as high as 50 per cent., but as hospitals naturally deal with the more severe cases this estimate may be too high. Undoubtedly a large proportion of rheumatic children become affected by some form of cardiac disability; and apart from economic loss inflicted by rheumatism there can, of course, be no doubt that the sufferings of children with advanced cardiac disease make any effort to discover prophylactic methods against rheumatism well worth any trouble and expense.

THE EDINBURGH MEETING: HOTEL ACCOMMODATION

THE Hotels and Lodgings Committee has practically completed its arrangements for coping with the large numbers who are expected to visit Edinburgh in July for the Annual Meeting of the British Medical Association. In order to secure the accommodation which is believed to be necessary, the Committee has definitely engaged all the available rooms in the city, and will allocate these to applicants in rotation. The Scottish Medical Secretary (Dr. Dreyer) has undertaken to do this work for the Committee, and applications for rooms should be sent to him at 6, Drumsheugh Gardens. A form for the purpose has been prepared for the convenience of members, and will be found on advertisement page 8 of this issue. It will be repeated in subsequent issues. The accommodation is grouped in three classes—namely: (1) Hotels, whose tariff for bed and breakfast ranges between 8s. 6d. and 14s.; the number who can be accommodated in these is comparatively limited. (2) Private hotels and boarding houses, at prices from 5s. 6d. to 8s. 6d. for bed and breakfast; of these there is a large number, all of them comfortable. (3) Hostels where the tariff is 8s. for bed and breakfast; not many of these are available, but those that are can be recommended. Garage accommodation has also been secured, and lodgings for chauffeurs. It will facilitate other arrangements if members who intend to be present at the Annual Meeting will notify their intention, whether they have already secured rooms or not. Early application for rooms is earnestly desired.

ILLICIT TRAFFIC IN DANGEROUS DRUGS.

THE revelations respecting the extent of the illicit traffic in opium, morphine, and cocaine, which have appalled and alarmed the Advisory Committee of the League of Nations dealing with these drugs of addiction, will not greatly surprise readers of the JOURNAL. On September 23rd, 1922, we wrote: "In these columns for the last decade we have uniformly urged the need for international control, not only of the distribution, but of the production of these perilous habit-forming drugs. So long as the actual growth of the *Papaver somniferum* and the *Erythroxolon coca* is unlimited and unsupervised the market will be liable to be flooded with their alkaloids and preparations and the excess of supply over legitimate demand will find its way into unlawful hands and be prostituted to vicious uses." The recent exposures of wholesale smuggling and illicit commerce, by post and otherwise, amply corroborate the view we then expressed. The League of Nations Advisory Committee, in a formidable document of sixty-one pages, cites case after case of hundreds of pounds of morphine and heroin which have been seized in transit. Large quantities of cocaine have similarly been confiscated, and in India alone it is probable that the illicit traffic in that alkaloid amounts to forty times the legitimate imports. A syndicate operating chiefly through Copenhagen was discovered which conducted a contraband trade in these drugs with the Far East "to an almost unbelievable extent." Another syndicate at Hong-Kong is chiefly engaged in the smuggling of Chinese opium. An alarming report from the chief of the Cairo police shows that Egypt is being drenched with heroin and cocaine, all of exotic production. "Egyptians," it is said, "are rapidly becoming a race of drug addicts, with disaster staring them in the face." More than 5,000 prosecutions in the year have been of little avail, as the enormous profits induce fresh traffickers to engage in this degrading commerce. It may well be asked, What has the League of Nations been doing with the convention signed at Geneva in February, 1925, from which, according to Mr. Zahle, the president of the second conference, such beneficent results were to be anticipated? The fact is this convention, which was to supersede and improve upon the Hague Opium Convention of 1912, cannot come into operation until ratified by at least seven of the States represented on the Council of the League, of which two must be States having permanent seats. Up to the present time only one permanent and one non-permanent member States have deposited ratifications. Moreover, the Geneva convention and protocol did not place any limitation on the production of opium, as was strongly urged by the American delegation. The Secretary of State for Foreign Affairs recently informed the House of Commons that "the Hague Convention of 1912 continues in operation as between the States parties to it," of which there are fifty-four. It is possible that the presumption that the Hague Convention of 1912 was to be superseded by that of Geneva of 1925 may have relaxed international efforts under the former treaty, which was binding and should be operative, in favour of the later treaty, which remains unratified and inoperative.

SPA TREATMENT IN BRITAIN.

THE current issue of *The Prescriber* is devoted to the subject of hydrotherapy. The editor, Dr. T. Stephenson, contributes an account of a visit he paid last July to eighteen British spas, and gives short descriptions of each, illustrated by reproductions of modern photographs and old engravings. An interesting account of spa treatment in the Middle Ages is supplied by Mr. John Hatton, director of the baths at Bath, the charm of which is considerably increased by Dürer's woodcut of "The men's bath," 1496, the fifteenth century drawing of "A ladies' bath," and views of the baths at Plombières in 1558 and 1747. Leamington, Malvern, and Torquay are singled out for consideration in special articles, details being given about facilities for treatment and the climatic and health conditions. Dr. Fortescue Fox, in a brief foreword, outlines spa treatment from the point of view of defence against disease, and pleads for the better co-ordination and scientific organization of medical hydrology. The numerous illustrations and the mass of useful information collected in this issue will be appreciated by those who desire to know more about available possibilities in this country for spa treatment, as compared with the well advertised foreign resorts. A guide to the British spas and climatic health resorts for 1927 has been compiled by Dr. Fortescue Fox, editor of the Health Resort Section of the *Medical Directory*, and is published by Messrs. J. and A. Churchill at the price of 1s. The general and specific indications to be considered in selecting a spa are enumerated, and short accounts are given of the federated and non-federated spas of Great Britain and New Zealand. Brief descriptions are supplied of the various marine and inland climatic resorts in Great Britain and Ireland. While on this subject we may mention that arrangements are being made by the Post Office authorities, through the British Spas Federation, whereby postmen and certain other members of the Post Office staffs will be able to obtain a course of spa treatment at any of the British spas at special inclusive terms. Owing to the nature of their work postmen are, perhaps, especially subject to rheumatism, and in future any who have been medically recommended for spa treatment will no longer be prevented from obtaining that benefit on account of the cost. The spa authorities have also offered to give every assistance in their power in helping to find suitable accommodation. This provision is of interest in view of the attention now being given to the question of making spa treatment available for insured persons suffering from rheumatic diseases—a subject discussed last week at a conference called by the British Medical Association, and reported in the SUPPLEMENT at page 85.

MEDICAL SOCIETY OF LONDON.

THE *154th anniversary dinner* of the Medical Society of London was held at the Grand Hotel on Monday, March 7th, with the President, Sir Humphry Rolleston, Bt., K.C.B., in the chair. The company included, besides those who spoke after dinner, the medical heads of the Royal Navy, Royal Air Force, and the Army Medical Service, the Chief Medical Officer of the Ministry of Health, and the Presidents of the Royal Society of Medicine, the Harveian Society, and the Chelsea Clinical Society. The toast of "Prosperity to the Medical Society of London" was proposed by Sir John Rose Bradford, President of the Royal College of Physicians, who complimented the society on its age and past services, its flourishing state to-day, and the pleasant house in which its varied work is done, and paid a warm tribute to the personal charm and diversified career of its President. Sir Humphry Rolleston, in replying, said that the present session had already proved most successful; fifty-one new members had joined, all the meetings were well attended, and, in short, the society, though old in days, was very young in its activities. In submitting the health of the visitors Dr. J. Walter Carr gave an amusing elaboration of the difficulties and possibilities of his task, and ended by calling upon Dr. John R. Lord, President of the Royal Medico-Psychological Association, to respond. Dr. Lord, while determined to tell no tales of lunacy, put in a claim for psychiatry as the chief branch of medicine, and speculated on some possible links between it and Lettsom, founder of the Medical Society of London. Mr. J. E. H. Roberts proposed the health of "all the distinguished people at this moment occupying the chair" in the person of the many-sided President, who, though now living in Cambridge, had attended every meeting of the society and of its council during the session. Sir Humphry Rolleston, in a brief acknowledgement, asked the company to toast the two energetic honorary secretaries, to whom the society owed so much, and the proceedings ended with replies by Dr. F. G. Chandler and Mr. Zachary Cope.

ADAPTATION TO ENVIRONMENT.

DR. A. K. CHALMERS, lately medical officer of health for Glasgow, in a lecture delivered not long ago at Greenock, dealt, among other topics, with the effects of acclimatization, understood in a broad sense, upon that portion of the population of Great Britain which, as industrialism developed, began to migrate from the country into the towns, producing gradually a disproportionate increase of persons of town parentage, so that three out of every four of the general mass of the people are now town dwellers. These industrial immigrants, when they made their way into the towns, met with new conditions. They found, it might be, a change of soil, or a change of climate such as, for example, increased humidity. Especially they encountered, in most cases, a new type of domestic environment, attended with crowding which favoured the spread among them of tuberculosis, specific fevers, and diarrhoeal disease, and an ensuing high mortality. These results were reflected in the general death returns. In 1849 the recorded death rate for England was 25 per 1,000; for Scotland in 1867 it was little short of 24 per 1,000. But acclimatization was at work, and began to tell. About 1875 the turning point was reached. The death rate in that year revealed a downward tendency, which proved to be persistent. By 1924 the death rate for England had fallen to 12.2 per 1,000, for Scotland to 14.4. It is not intended to maintain that this acclimatization, or adaptation to circumstance, took place on the human side only. Environment too was undergoing modifications of a far-reaching character. The reduction of crowding, both of people in dwellings and of dwellings on site, the abundance of pure water, the introduction of efficient scavenging, and the betterment of working conditions in factories—these and kindred improvements all played their part in bringing about changes, for man may not only adapt himself to his environment as occasion requires, he may also adapt his environment to himself to suit his special needs. The advance which has been made along these lines since the date of the turning point is well brought out for an industrial city by the life tables recently issued in Glasgow. They show that of every 100,000 boys born in Glasgow in 1871, 40,000 reached their fifty-fifth year; of an equal number born in 1921, 60,000 may expect to reach that term. The increased expectation of life enjoyed by the present generation is largely due to reduced death rates in the earlier years. These observations by Dr. Chalmers, like all his work, are a stimulus to reflection. Adaptation, however, is still regrettably incomplete, for the different organs or systems of man, whether circulatory, respiratory, digestive, or nervous, show varying powers of

resistance to the assaults of environment. Man's life does not cease through a simultaneous collapse of his whole bodily fabric: it is a lesion in one system, like the rift within the lute, which will slowly silence all. If the great general infections like small-pox and typhus have lost some of their terrors, their places are being taken by a new cohort of diseases which strike at particular organs. Cancer, pneumonia, and heart disease, for example, appear to be increasing in prevalence. Nor should we plume ourselves overmuch upon our falling general death rate: our blind, our defectives, and the certified inmates of our asylums must be counted in if we would complete our list of casualties. Like untimely deaths, they are the result of the imperfect adaptation of an organ or system to the conditions of modern life, and they equally call for prevention. Dr. Chalmers and his contemporaries quelled the great fevers and raised the standards of living. The medical officers who are following in their footsteps may find in mental deficiency and cancer and its allies not less challenging problems.

EYE-STRAIN IN INDUSTRY.

A VALUABLE piece of research work[1] on the effects of eye-strain on the output of linkers in the hosiery industry has been done by Mr. H. C. Weston, M.J.Inst.E., and Mr. S. Adams, M.Sc. In the examination of the eyes of the workers engaged in the industrial part of the experiment they were assisted by Mr. W. B. Laws, F.R.C.S., of Nottingham. Many industrial processes demand for their effective performance the clear perception of fine detail, and some evidence already exists that continuous work of this nature tends to have a deleterious effect upon eyesight. Harman's investigation of the history of 480 myopic subjects is cited; it revealed the fact that of those who had not been engaged in fine processes 9.4 per cent. had failed owing to visual troubles at some time during their occupations, and that of those 7 per cent. sustained definite damage to their eyes; of those who were so engaged the corresponding numbers rose to 53 per cent. and 15 per cent. The perception of fine detail depends upon the operation within limits of two factors—the size of the retinal image and the illumination on the object viewed. When the light is too low, then the only resource is to get close to the object and secure a larger image, with resultant extra strain from excessive accommodation. In certain extreme operations the details are so exceptionally fine that illumination, however high, does not wholly eliminate the need for very close vision with its excessive strain. "Linking" is such a process. The work is part of stocking making. The hose comes from the knitting machine with the toe unfinished; it is left in some 220 fine loops, and these have to be linked together on a special machine. A slowly revolving disc is furnished with needles, which measure five-sixteenths of an inch in length, and some twenty to twenty-two go to the inch in lateral measure. The operative sits on a low stool with eyes some five to eight inches from the fabric. The work takes some 75 to 80 per cent. of the time of their employment. The highest average of the quickest operative was four and a half dozen pairs of hose every hour. Such work as this must demand a high degree of accommodation and convergence of the eye, which must be maintained over long periods; moreover, the eyes are fixed upon a very narrow area, so that staring is compulsory. It is known that squint is not uncommon amongst the workers, and Italian observers have noted diminution of field of vision and of visual acuity, and other signs of eye-strain. A considerable number of linkers find it necessary to wear glasses, and probably many more ought to do so. Mr. Laws's investigation shows that for emmetropic eyes the assistance of glasses with lenses of +1.5 D. sphere is of most general use. The lighting conditions under which the work in these experiments was conducted were excellent; the daylight average at the site of the work in December varied from 16 to 34 foot-candles, with an average of 24.5. The artificial lighting was well arranged, and gave from 29.5 to 16.5 foot-candles at different parts of the field of work. The output of three operatives was recorded, first without glasses for one week, and secondly, with glasses for another week. The records of the experiments are given in detail, with curves of output from day to day, and in the morning, midday, and afternoon. The data show that the use of the glasses has been followed by two important results: First, the general rate of output was increased, for a saving was effected during each period of the day glasses were worn. Secondly, the shape of the output curve was improved; the usual fall in the afternoon spell was frequently reversed when glasses were worn. That is clear evidence of a reduction of fatigue. The spectacles relieved only the strain of extreme accommodation; it is possible that prisms to aid convergence might secure even better results. The operatives appreciated the value of the glasses, for they continued to use them after the experiment was ended. Notes of their own observations were made; it is sufficient to quote one of these: "I have had the glasses you gave me about a month now, and I get several benefits from them. They are very comfortable to wear and ease the eyes. I can also see my work clearer, and my eyes never ache now at night. I am able to get more work off with them." The experiment shows the need for the systematic examination of the eyes of operatives engaged upon fine work, the correction of such errors of refraction as may be present, and the advantage of making special provision of glasses for the performance of excessively fine work.

[1] *The Effect of Eyestrain on the Output of Linkers in the Hosiery Industry.* By H. C. Weston, M.J.Inst.E., and S. Adams, M.Sc., Industrial Fatigue Research Board of the Medical Research Council. London: H.M. Stationery Office. 1927. (Pp. 21. 1s. net.)

THE THERAPEUTICS OF MANGANESE.

DURING the past two years Dr. H. W. Nott has published in this JOURNAL[1] reports on the effects he has observed following the rectal injection of solutions of potassium permanganate accompanied by oral administration of dried thyroid. He has found the beneficial results especially striking in pneumonia. An article by Dr. N. J. Roche, published in this issue, tends to confirm Dr. Nott's conclusion. The local effects cannot be ignored, for the permanganate has a considerable action on the mucosa of the colon, as is shown by the fact that the patients often subsequently pass strings of mucus, or even mucous casts of the bowel. The nature of the results observed suggests, however, that some general effect is produced, and it is therefore interesting briefly to consider the known pharmacological actions of manganese. Information as to the action of manganese on animals in non-toxic doses is comparatively limited, although traces of this metal are well known to produce a marked stimulant action on the growth of plants. Bertrand has also drawn attention to the fact that an artificial oxidase can be produced by precipitating gum arabic containing a small amount of manganese.[2] Later workers have, however, stated that similar oxidases can be made in the absence of metals. The most remarkable pharmacological action of manganese is that discovered by Walbum,[3] who found that intravenous injections of manganese chloride caused a rise in the antitoxin titres of goats and horses that had previously been immunized to diphtheria toxin. This has been confirmed by other workers,[4] who found, however, that the increase in antitoxic titre was only temporary, and that none occurred when

[1] BRITISH MEDICAL JOURNAL, March 7th, 1925; December 26th, 1925; July 17th, 1926.

[3] *Biol. Meddels.*, 3, 1921, 1; *C.R. Soc. de Biol.*, 85, 1921, 761.
[4] Walbum and Mörch, *Ann. de l'Inst. Pasteur*, 37, 1923, 396; Pico, *C.R. Soc. de Biol.*, 91, 1924, 1049; Schmidt, *Zentralbl. f. Bakt.*, 95, 1925, 74.

the salt was given by the mouth. The results of these experiments, however, suggest a possible explanation of the remarkable results recorded by Dr. Nott. Mention may also be made of the observations of Levine and Solm,[5] who found that small amounts of manganese added to the food of young rats appeared to improve their general health.

HOW INFLUENZA KILLS.

DURING the epidemic of influenza in France, where it has been widespread, Drs. Maurice Renaud and Charles Juge had the opportunity at the hospital at Brévannes of making some interesting observations, which they recently communicated to the Académie de Médecine, Paris. They divided the cases according as they occurred in healthy adults, in patients with chronic disease, and in the aged. In healthy adults the attacks began with malaise, a sudden rise of temperature, and a nasopharyngeal catarrh which tended to extend to the bronchi; in the more severe cases the inflammation spread to the smaller bronchial tubes or to the lung, producing bronchopneumonic patches or even lobar hepatization. All the patients recovered in a fortnight, defervescence taking from forty-eight hours to four or five days. Of 600 persons ranked as chronic invalids, 10 per cent. were attacked; in half these cases the disease was mild, and recovery was rapid in spite of arteriosclerosis, cardiac insufficiency, and renal or even pulmonary trouble. In the other half the influenzal attack became serious in consequence of pulmonary lesions, with abundant purulent expectoration and evidences of myocardial fatigue. Ten per cent. of the chronic invalids attacked died with grey hepatization of lobar pneumonia and massive bronchopneumonic patches. In the aged the disease was very grave, and about 30 per cent. of those attacked died; while another 30 per cent. were so exhausted that it seemed unlikely that they would live long. The aged patients who died had comparatively mild attacks, with defervescence about the third day; but death followed in seven to ten days from progressive weakness. Nevertheless, *post-mortem* examination showed extensive grey hepatization of the lungs. The observers considered that these results confirmed their view that influenza was only serious by reason of pulmonary lesions, which were secondary complications due to streptococci and pneumococci, and often arose in mild cases of influenza when the patients exposed themselves to chill, fatigue, and other debilitating influences. They produced death through asphyxia. Treatment by the intravenous injection of adrenaline-serum was generally efficacious. Drs. Renaud and Juge summarized their faith as follows: Influenza treated early and in a suitable manner is only dangerous in exceptional cases. The treatment should be purgation, tonic treatment for the heart, and cold hydrotherapy. There are no grave forms of influenza; serious attacks are those aggravated by complications, which are favoured by senile weakness, organic defects, and accidental external influences. In fact, influenza is only serious in the absence of wisdom and prudence.

THE TREATMENT OF MALARIA.

THIS is an age of synthesis, and some years ago tropical medicine had to welcome the German preparation called "Bayer 205," which has proved to be of great value in the treatment of sleeping sickness both in man and animals. Elsewhere in this issue we report (p. 466) a paper by Dr. Manson-Bahr on his experiences with another Bayer synthetic drug called plasmochin, which it was hoped would give similar results with malaria. Dr. Manson-Bahr's analysis of his cases shows that apparently the pure drug is fairly effective in the treatment of benign tertian malaria, and, in combination with minute quantities of quinine, in the treatment of subtertian malaria. It has a low factor of safety, however, and a slight overdose causes cyanosis, sometimes accompanied by methaemoglobinuria. The advance made by the production of this drug is its apparently selective action on the malarial "crescents" or subtertian gametocytes. Finality has not yet been reached and the drug is still in the experimental stages, but the results are distinctly hopeful. In Dr. Manson-Bahr's words, plasmochin "must be regarded as the beginning, not the climax, of a new series of antimalarial drugs."

HERBS OF HEALING.

MR. EDWARD STEP, F.L.S., who has written some deservedly popular books on British plants and flowers, has produced a treatise on some of the best known of the many indigenous plants which once were of good repute for their healing qualities.[1] He deals with some 170 species, but has had to leave out a large number whose virtues, once vaunted, are now forgotten. For has not Mr. Rudyard Kipling told us that

> Anything green that grew out of the mould
> Was an excellent herb to our fathers of old;

and did not Dr. Nicholas Culpeper, that prolific writer on medical astrology, therapeutics, and herbalism, publish in 1653 a work on 369 medicines made of English herbs? Mr. Step's present collection cuts but a poor figure beside such an imposing botanical array, but nevertheless he has included all those of which the potency is nowadays admitted, and probably all or most of those which our modern herbalists still collect and sell. What with plants under planetary patronage, which were reckoned to work cures in diseases caused by stellar influence, and those whose functions were marked out by the doctrine of signatures, there were plentiful indications for the prescriber of the seventeenth and previous centuries. Culpeper, of whom Mr. Kipling has drawn an attractive sketch in *Rewards and Fairies*, was not singular in his therapeutic beliefs, and his quarrel with the College of Physicians was not provoked by any unorthodox views of his, but by his poaching on their preserves in translating their pharmacopoeia into his London dispensatory. Among the herbs described by Mr. Step are those which produce some of the most powerful vegetable poisons known to us, and it is puzzling to find that the same natural order may contain many innocent as well as some most noxious herbs, sometimes resembling one another so closely that the superficial observer may easily make fatal mistakes, as the records of toxicologists tell us has too often happened. Such resemblances are to be found in the Umbelliferous Order in particular, in which the deadly hemlock-water-dropwort (*Oenanthe crocata*) much resembles the wholesome celery, and the fool's parsley has been eaten in the place of the familiar parsley of the garden. Other natural orders are less mixed in their properties, for the Ranunculaceae and the Solanaceae are almost wholly noxious, in their raw state at least, while the Cruciferae are all wholesome or harmless. We do not know how it comes about that from the same non-organic constituents substances of such varying potency are constructed in the laboratories of plants which have so many common characteristics. Imagination boggles at the thought of the task of remembering the therapeutic qualities ascribed to each of Culpeper's plants, or even of the modest 170 of Mr. Step, but the herbalist physician could console himself with the knowledge that every one of these herbs—deadly ones excepted—had so many qualities that often one would do in place of half a dozen others. Indeed, there were a few plants which seem to have been equivalent to a whole medicine chest. Mr. Step tells us that "an

[1] *Herbs of Healing.* By Edward Step, F.L.S. London: Hutchinson and Co. (Publishers) Ltd. 1926. (Demy 8vo, pp. xiii + 206. 10s. 6d. net.)

Italian proverb counselled you to sell your coat and buy betony," which was highly recommended as a panacea by Antony Musa, the physician to Augustus Caesar; and vervain, the *herba sacra* of the Romans, had at least an equally good reputation. It is a comfort to a lover of the English countryside to reflect that such powerful herbs as are really in demand by the wholesale druggists are specially cultivated in gardens, and that, despite an attempt during the war to revive the use of other indigenous herbs, their collectors are few. Were it otherwise, and were all the simples known to Gerarde and to Culpeper sought for diligently, our native flora must have long since disappeared almost entirely instead of partially—but all too disastrously—in the neighbourhood of our towns, where nature students and hawkers and school children have wrought such havoc. In a high-banked shady lane twenty miles from Charing Cross twenty-three species of ferns were to be found a generation earlier; a few years ago there was no wild fern but bracken to be found in the district.

AN AUSTRALIAN DIPLOMA IN TROPICAL MEDICINE.

AUSTRALIAN medical graduates desiring to fit themselves for practice in tropical Australia or in British New Guinea, which is committed by mandate to the Commonwealth, have hitherto looked to England as the least inaccessible school open to them for the study of tropical medicine, but have been debarred in many cases by considerations of time and expense from seeking the diplomas there obtainable. To meet their requirements in a more convenient manner an Australian Diploma in Tropical Medicine has been established. The course, which lasts for three months, is held at the Australian Institute of Tropical Medicine at Townsville in tropical Queensland. At the close of the training a twelve days' examination on a lower grade takes place, and successful candidates receive a certificate. Following this comes a higher grade examination, also of twelve days' duration, for the D.T.M., which is granted by the Universities of Melbourne, Sydney, and Adelaide. The higher examination is more exacting than that for the certificate, and demands a much wider range of knowledge. Candidates must be qualified medical practitioners registered in a State or in the Commonwealth. A period of not less than twelve months must have elapsed since the date of their obtaining their registrable qualification. They must have passed Part I of the examination for the D.P.H. of their university, or, alternatively, must have pursued a prescribed preliminary course of laboratory instruction of at least one month's duration. The first course of training at Townsville has recently been completed. The whole class suffered from dengue fever. This was a touch of realism and gave the tropical setting, but practical experience carried to these lengths is not a guaranteed feature of the course. The convalescence of one student was unfortunately so prolonged that he fell out of the running; the rest obtained the certificate. Dr. R. L. Bellamy, who passed the higher examination, won for himself and for the University of Sydney the distinction attaching to the first Diploma in Tropical Medicine granted in Australia.

THE ANTIRACHITIC VITAMIN.

ROSENHEIM AND WEBSTER showed two years ago that cholesterol which was then believed to be pure was rendered antirachitic by exposure to ultra-violet light. This fact seems to have been discovered independently about the same time by Steenbock and by Hess. It was next discovered that cholesterol purified by certain processes could not be activated. Windaus found that a common impurity of cholesterol called ergosterol was destroyed by these same processes of purification. Ergosterol is a sterol first isolated by Tanret from ergot, but which occurs in a wide range of lower plants. More recently Rosenheim and Webster found that ergosterol showed intense absorption of ultra-violet light at 2,800 A.U., and that exposure to ultra-violet light produced in ergosterol a much more potent antirachitic action than had ever been obtained in any other substance. They have cured and prevented rickets in rats with a daily dose of 0.004 mg. of irradiated ergosterol, and they believe that the limit of activity will prove to be less than 0.001 mg. The British Drug Houses inform us that they are making ergosterol, and that they are in a position to supply to any medical man who wishes to make a clinical test a solution of 0.1 per cent. of crystalline ergosterol which has been activated by irradiation under carefully controlled conditions. So far as can be foretold, this solution may be expected to possess twenty to fifty times the antirachitic action of cod-liver oil, and therefore the effective dose should be from 1/4 to 1 c.cm. The British Drug Houses offer to send a sample of this solution without charge to any registered medical practitioner who may apply to them for it.

INFLUENZA.

ALL the information points to a subsidence of the influenza epidemic throughout the country. The total number of deaths from this cause reported in the great towns of England and Wales during the week ended March 5th was 898, compared with 1,025 in the previous week. In London 69 deaths were notified, as compared with 81, and in the outer ring of the metropolis 44 as against 67. From Manchester 70 deaths were reported, from Birmingham 51, from Liverpool 46, from Sheffield, Blackburn, and Bolton 35 each, and from Burnley 29. Influenza, of a mild type, is still very prevalent in Scotland, and reports for the same period furnished to the Scottish Board of Health show a heavier incidence in a number of districts; but though there are still many cases in Dundee the epidemic there seems to be on the decline, and there is a definite improvement in Aberdeen. In Glasgow mild influenza is prevalent, with few severe cases, while in Edinburgh there is no evidence of an epidemic, though the number of deaths associated with influenza was exceptionally high last week. In the north of Scotland the crest of the wave seems to have passed, except in outlying districts which the infection has but recently reached.

LISTER CENTENARY CELEBRATIONS IN LONDON.

AT the reception of delegates by the Prime Minister, which will take place at 11.30 a.m. on Tuesday, April 5th, in the Great Hall of the British Medical Association's House, after making provision for the official delegates and the members of the Lister family there will be some 500 seats available for members of the profession and of the general public. It is hoped that there will be a large and representative gathering. Members desiring tickets for themselves and friends are requested to make application by letter to the Financial Secretary, British Medical Association House, Tavistock Square, W.C.1.

BY the instructions of the Council the Science Committee of the British Medical Association is convening a conference in opposition to the Dogs' Protection Bill. It will be held in the Association's House on Monday, April 4th, at 4.30 p.m. Invitations are being issued to universities, medical schools, and other medical and scientific societies; also to representatives of the veterinary and dental professions. Fuller details will be published in the next issue of the JOURNAL.

THE REPORT OF THE ROYAL COMMISSION ON LUNACY.

SCOTTISH EXPERIENCE.

DR. GEORGE M. ROBERTSON, physician-superintendent of the Royal Edinburgh Hospital, Morningside, like his predecessor, Sir Thomas Clouston, has accustomed us to look in his annual report for something more than a bare record of facts relating to the hospital; we have been taught to expect an expression of opinion on some of the most important events of the year affecting the work of psychiatry and the administration of lunacy laws. This year we are not disappointed, for Dr. Robertson has some observations on the report of the Royal Commission on Lunacy and Mental Disorder. As he is not only physician-superintendent of a famous asylum, but also professor of psychiatry in the University of Edinburgh, and physician-consultant in psychiatry to the Royal Infirmary, Edinburgh, his opinion will command attention. It is very outspoken, and the best thing to do seems to be to quote it in full:

The most important event in the medico-psychological world last year was the drawing up of the Report of the Royal Commission on Lunacy and Mental Disorder, which is admitted by experts to be a wonderful achievement. The most striking departure from established principle that it contains is the frank acknowledgement, made for the first time, that the treatment of mental disorder is essentially a medical question; that the cure or alleviation of the symptoms from which the patient suffers must be the primary and paramount consideration.

Strange as it may appear, the existing lunacy laws, particularly those of England, seem to have been devised with the perverse object of obstructing anyone desiring to obtain medical relief. In other forms of ill health the patient can go voluntarily to a hospital to seek advice and treatment, and, naturally, he goes as early as he possibly can. In the case of mental illness, however, the laws of England enact that patients applying for treatment voluntarily must be refused admission to mental hospitals that have been erected by the ratepayers for the express purpose of treating this form of illness. To treat patients in these hospitals in this way is illegal; it is a misdemeanour for which the physician renders himself liable to a heavy fine.

Further, no one can be admitted to a public mental hospital until his disease has become thoroughly established or his conduct has become a public nuisance or a scandal. Even then he is not permitted to receive treatment till his application for admission has been dealt with after the manner of the detention of a criminal—namely, by a legal order or authority. Such a method of treating a sick person and of handling a question of public health is cruel, and an abomination to anyone inspired by medical sentiments and ideals.

One result of these evil methods is that hospitals for the treatment of mental disease have not unnaturally fallen into disrepute. Although specially designed for the treatment of mental disease, although equipped at great cost with all the resources that science demands, they are the very last places in the world to which the public will send patients for treatment. Yet there is no form of hospital in which more devoted or more self-denying work is done—work, however, that receives scant public recognition, and is patiently undertaken often under unmerited abuse.

The lunacy laws were framed with an intention that was not the outcome of a knowledge of disease, or of sympathy with the sick, but of something very foreign to the spirit of healing. A short practical test discloses the weakness of these Acts, but such is the difficulty of getting medical views accepted, so great is parliamentary inertia, that, though often promised redress, we have waited for it in vain. The appointment of a Royal Commission was therefore hailed as a godsend, and we all look forward to the initiation at last of a happier era.

I desire to utter a note of warning: after the lunacy laws of England have been remodelled, the laws of Scotland will next require to be dealt with. It is not to be assumed that the recommendations of the Royal Commission apply to Scotland, or are the last words on the subject. Whatever may be the reason, the medical character of the laws of Scotland are far in advance of those of England, and to apply to Scotland some of the recommendations, applicable only to England, would be to set back the hands of the clock fifty years.

In England the magistrate, who signs the order of admission to a mental hospital, sees the patient, and has to form an independent judgement as to his soundness of mind. In Scotland the sheriff accepts the written testimony of medical men, given on oath, in the form of certificates. In other words, in England a layman decides, while in Scotland the problem is regarded as a medical one, and this principle has worked most satisfactorily.

Many years ago a patient of mine, who, under treatment, ultimately made a good recovery, was seen by the Lord Mayor of London, acting in his capacity as a magistrate. His lordship refused to incur the responsibility of signing the order of admission. I did not blame him, for I question if he had any knowledge whatever of mental disease. He lacked confidence in his medical judgement, and, like the cautious man he was, he played for safety—his own. It must not be overlooked, too, either in explanation or in extenuation, that his interview with the patient is said to have lasted only a minute, and to have taken place within the precincts of a taxi-cab! This unmedical form of procedure is approved by the Royal Commission, but it is hoped that nothing so alien and retrograde will ever be introduced into Scotland.

In the second place, the responsibility for the treatment and discharge of patients in Scotland rests entirely in the hands of medical men. In England, on the other hand, it rests entirely with the visiting committee, which consists of laymen. They, almost invariably, have the good sense to act in accordance with the medical advice given to them—though not always. This unmedical form of procedure is also perpetuated in the recommendations of the report, although it is qualified by the proviso that the committee must be unanimous if it acts contrary to medical advice.

As the Commission attaches such weight to the advice of the medical superintendent—his opinion *plus* that of one member outweighing the opinion of the whole visiting committee *minus* one member—it would have been more logical and direct to have adopted the sound medical practice of Scotland, instead of contemplating what amounts almost to a psychological miracle.

In concluding this part of his report Dr. Robertson expresses the hope that when the time comes to frame new lunacy laws for Scotland an advisory council will be appointed to co-operate with the General Board of Control. He suggests that such a council might be formed from the medical superintendents of mental hospitals in Scotland, and recalls that owing to the absence of such co-operation when the last lunacy bill was framed provisions relating to the Royal Asylums were introduced which had to be withdrawn in committee, thus leading to unnecessary expenditure of time and money.

ADMINISTRATION AT MORNINGSIDE.

In the earlier part of his report Professor Robertson states that the two departments into which the Mental Hospital is divided, Craig House with its villas, and the West House, were both fully occupied during the year. Every class of private patient is provided for—from those paying low rates of board to those who are able to pay high rates for special accommodation and attendance. The number of persons admitted was 249, the great majority being voluntary patients. In this way the "objectionable features of the obsolescent and universally detested method of certification" were avoided. In Scotland from 60 to 80 per cent. of private patients of the richer classes enter mental hospitals as voluntary patients, and certification, Professor Robertson says, is looked upon as the very last resort. He expresses regret that parochial patients are not encouraged to enter mental hospitals voluntarily. It appears that parochial authorities have been under the false impression that if they allowed this they would lose the Government grant, whereas if the patient enters voluntarily the expense of certification is saved, if he receives an old age pension he is not deprived of it, and the Government grant is not affected one way or the other.

A new nursing home, which is the sixth taken over by the managers of the hospital, was opened last year; it is a fine mansion house standing in an old park within half an hour's run from Edinburgh. The managers are now giving attention to the provision at Morningside of a psychopathic hospital in a separate block with its own entrance. The hospital will have the same legal status as the Royal Infirmary, and has been established because that great institution has no space to provide for the mentally sick. It will be known as the Jordanburn Hospital, and will eventually have an out-patient department, but a new wing, consisting of a waiting-room, medical examination rooms, and consulting-rooms, will have to be built at a

cost of £10,000. An appeal for this amount, and for the erection of a lecture theatre also, is made to the public.

Among recent additions to the equipment of Morningside Hospital are an occupational therapy department, cinematographs, and a wireless installation.

The report gives a short account of the first year's work of the mental out-patient clinic at the Royal Infirmary. Only 180 patients have attended, but many have acted upon the recommendation to seek advice in every difficulty which confronts them.

England and Wales.

ST. BARTHOLOMEW'S HOSPITAL: PROPOSED NEW SURGICAL BLOCK.

THE Lord Mayor of London on March 1st inaugurated an appeal for £200,000 for the building and equipment of a new surgical block at St. Bartholomew's Hospital, London, and additional accommodation for nurses. Lord Stanmore, treasurer of the hospital, mentioned that the present ward blocks were more than two hundred years old, and were unsuitable for the scientific requirements of the present time. Some of the operation theatres had been built as temporary erections twenty years ago; they had no direct connexion with the wards, and patients had to be transferred across the square whatever the weather conditions might be. It was now proposed to erect a building five stories high with two wards, each of twenty-five beds, and an operation theatre on each floor. An electro-therapeutic department would be installed in the basement, and on the roof there would be new laboratories. Sir Berkeley Moynihan, Bt., President of the Royal College of Surgeons, supported the appeal with a laudatory account of the achievements and high ideals of the hospital. Although the staffing of the surgical side met all demands the operative department was, he said, structurally below the standard of provincial hospitals. Sir John Rose Bradford, President of the Royal College of Physicians, also commended the appeal.

MAUDSLEY HOSPITAL COURSES.

The following afternoon lectures and courses of practical instruction for the diploma in psychological medicine have been arranged at the Maudsley Hospital during the spring. On Mondays, commencing March 14th, four demonstrations with practical instruction in laboratory methods will be given by Mr. S. A. Mann, and twelve clinical demonstrations in neurology on Thursdays will start on March 17th, the first six being given by Dr. F. L. Golla at the Hospital for Paralysis and Epilepsy, Maida Vale, and the second six by Dr. F. M. R. Walshe at the National Hospital for Paralysis, Queen Square. Dr. F. C. Shrubsall will give six lectures on the practical aspect of mental deficiency on Tuesdays, commencing March 15th; and Dr. A. A. W. Petrie will give three lectures on therapeutics on Fridays, commencing March 18th. Eight lectures on morbid psychology will be delivered by Dr. Edward Mapother on Wednesdays, commencing March 30th; and two lectures on abnormalities of the fundus oculi will be given by Mr. R. Foster Moore on April 25th and May 2nd. Dr. Edward Mapother will also hold six demonstrations in clinical psychiatry on Wednesdays, commencing April 27th. The legal relation of insanity and its treatment will be dealt with by Dr. Norwood East on Tuesdays, commencing May 3rd. On Fridays, commencing May 6th, four lectures on the pathology of mental diseases will be given by Dr. Golla, each of which will be followed by a demonstration in pathological anatomy by Mr. Charles Geary. Dr. Bernard Hart will deliver eight lectures on the psychoneuroses on Mondays, commencing May 9th. Further information about these lectures and demonstrations may be obtained from the director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5, and the Fellowship of Medicine, 1, Wimpole Street, W.1, will collect fees from the medical practitioners introduced by the Fellowship. A limited number of clinical assistantships are available at the hospital, either whole-time or part-time. These are recognized as constituting the clinical experience required for the diploma, and inquiries regarding them should be made to the medical superintendent of the Maudsley Hospital.

KING EDWARD VII SANATORIUM, MIDHURST.

During the twelve months ending June 30th, 1926, 268 patients were admitted to King Edward VII Sanatorium at Midhurst, including 35 re-admissions, and 196 patients were discharged, as compared with 213 who left the sanatorium in the previous year. The medical superintendent, Dr. R. R. Trail, in the twentieth annual report of this institution, ascribes the decline in the discharge rate to the greater number of artificial pneumothorax cases now being treated; the length of stay for these patients is necessarily greater than for those otherwise treated. The average waiting list has slightly increased. A statistical report on the treatment of 185 patients shows that in 63 the disease was arrested, in 33 the condition was much improved; 62 patients were definitely benefited, 26 remained stationary or became worse, and one died. As in the previous report comment is made that Midhurst still draws about half its patients from London and the home counties, and attention is again directed to the fact that members of the professional classes, for whom it was originally intended, do not make enough use of the sanatorium.

CORONERS' INQUESTS IN LONDON.

The number of deaths reported to the coroners in London during 1926 was 6,934, and the number of inquests held was 5,143, an increase of 103 upon the previous year. *Post-mortem* examinations were necessary in 88 per cent. of the inquests, and in 118 cases the examination was conducted by a special pathologist. A verdict of murder was returned in 22 cases, and of manslaughter in 18. The total number of suicides was 600, as against 515 in the previous year. Want and exposure accounted for 18 deaths, excessive drinking for 28, want of attention at birth for 57. In all, 1,760 people met their death by accident, as against 1,761 in 1925, and 1,607 in 1924. A verdict of "death from natural causes" was returned in 2,447 cases. The total cost to the London County Council of the inquests held in 1926 was £25,732. Only 230 of the inquests were held with juries. The fees paid to special pathologists amounted to £381, and to toxicologists, in connexion with fifteen inquests, £78.

ARTIFICIAL LIGHT TREATMENT SCHEME FOR LONDON.

The London County Council a year ago made a grant of £600 towards the provision, in connexion with metropolitan borough councils' dispensary schemes, of artificial light treatment for tuberculous patients at certain hospitals and other approved centres in London. Up to the present only ten borough councils have taken advantage of the scheme, at a total cost of £463, which, on the basis of an average of thirty exposures a patient, represents the cost of treatment of about 300 patients. It is proposed to extend for another year the experimental period, which was originally arranged for only twelve months, as sufficient experience has not yet been gained to form an opinion as to the value of the arrangement.

VENEREAL DISEASES IN LONDON.

It was reported to the London County Council this week that under the scheme for the diagnosis and treatment of venereal diseases the total number of new cases attending the London hospitals which receive grants-in-aid from the Council was 26,712 in 1926. Of this number, 8,988 were found to be not infected, and of the remainder the cases of syphilis numbered 5,738, of gonorrhœa 11,683, and of soft chancre 303. It is explained that these figures are not the full measure of the extent to which venereal diseases come under treatment in London, as a not inconsiderable number of cases receive treatment by general practitioners. The number of attendances of patients at hospitals was 687,075. The corresponding figures for 1925 were 26,182 cases (of which 8,680 were found to be non-venereal), and 646,131 attendances. The bacteriological specimens examined at hospitals at the request of and free of cost to practitioners numbered 27,565, an increase on any previous

year, and 439 practitioners are on the approved list for the supply free of cost of salvarsan or its substitutes. Provisional grants amounting to £103,085 are to be made for treatment and pathological work at hospitals in 1927-28, £5,350 for hostels, and £20,000 as a contingency provision to cover possible expenditure in respect of developments. Six adjoining counties and three county boroughs join with London in the scheme.

Scotland.

LISTER CENTENARY IN GLASGOW.

A COMMITTEE has been formed in Glasgow, composed of representatives of public bodies and scientific societies, to celebrate the centenary of the birth of Lord Lister. This is most appropriate, for it was in Glasgow that he laid the foundations and gave to the world the firstfruits of his investigations into the use of antiseptics. April 1st has been chosen as the date of the celebrations in Glasgow; they will begin with an official religious service in the cathedral at 11 a.m.

CARE OF CRIPPLED CHILDREN.

A public conference was held in the City Chambers, Edinburgh, on February 25th, at which Lord Provost Stevenson presided, to initiate a scheme for promoting the treatment and care of crippled children in the south-eastern area of Scotland. A committee appointed nearly a year ago by a similar conference recommended the establishment of a new central orthopaedic hospital on the outskirts of Edinburgh; the formation of major clinics in important centres of population in the south-eastern area of the country; the formation of minor clinics as might be necessary, linked up with the major clinics; and the establishment of co-operation between the existing hospitals and the new orthopaedic hospital. The committee stated that the Scottish Board of Health would be prepared to approve of grants by local authorities for maintenance of patients in such a hospital. The patients the hospital would admit were children suffering from tuberculosis, under schemes for treatment of this disease; children under 5 years of age, under child welfare schemes; and physical defectives from 5 to 16 years of age who were necessitous and came under the education authorities. The provision at present existing was inadequate, and many patients who might have been restored to good health were at the present time becoming permanently crippled. Though the scheme might at first be restricted to children under the age of 16 years, it was hoped that ultimately it would embrace the treatment of cripples at any age. The committee recommended a hospital of 75 beds, for which the probable cost would be £10,000 for site, £25,000 for administration block with operating theatre, and £15,000 for the hospital itself. The committee recommended, however, that the charitable public should be asked to subscribe not less than £75,000. Sheriff Crole, K.C., chairman of the committee, in moving the adoption of the report, stated that investigations had been confined to the area between the Tay and the Tweed, and Sir David Wallace, F.R.C.S., in seconding, said that the scheme was imperatively needed on the evidence brought before the committee. Lord Mackenzie, in commending the scheme, which was adopted, said that the estimated cost was not excessive, but there was a need for a central co-ordinating authority.

HEALTH IN INDUSTRY.

The first annual meeting of the Industrial Health Education Society, an organization which last year succeeded the Industrial Health Education Council, a purely Scottish body, was presided over by Sir William S. Haldane, who said that the purpose of the society was to combat the evils of ill health among the industrial classes by the spread of knowledge as to how health was to be maintained. The work came to be undertaken because of the realization of the immense extent of preventable sickness, largely of occupational nature. It had been reckoned that among insured persons at least 26 million weeks a year were lost through sickness, for which benefit was payable. Educational methods had seemed the surest means of enabling the workers to defend themselves against the prevailing evils of ill health affecting particular occupations. During 1925 meetings of workers had been organized throughout Scotland, mainly in mining and industrial areas. In this initial effort the society had had great help from the medical profession, and had been still further encouraged by the wonderful appreciation of the workers themselves. Before the end of 1925 the work had been extended to Newcastle-on-Tyne, where Sir Thomas Oliver had given invaluable help with his knowledge of occupational disease. The organization had subsequently been extended so that five area councils, covering the whole country, had now been established. Last year the work had increased 50 per cent. on that of 1925, and for the first three months of the present year 50 per cent. more engagements than for the whole of 1926 had already been fixed. Mr. Robert Smillie, M.P., said that he was glad that the great work undertaken had the approval both of the employing classes and of the working classes, for nowadays it was almost impossible to get these two to agree on anything. He recognized that medical men, while carrying out their work, could not enter into explanations as to the necessity for doing everything for the preservation of health, and something was required in the shape of lectures to help people to realize that to some extent they had their health in their own hands. He could speak on behalf of the mining folks when he said that men and women were delighted with the lectures delivered under the auspices of the society, and on behalf of the British Trade Union Congress he wished great success to the work. Sir John R. Findlay, in moving the adoption of the report, referred to the habit in illness of waiting till the mischief was done before calling in the doctor. One of the achievements of this society was, he thought, the extent to which it had enlisted the ready and willing services of the medical profession in its great endeavour. Lord Salvesen said that it should be emphasized that the objects for which the society had been instituted were non-controversial and non-political. It had the goodwill, not only of the Trade Union Congress, but of the employers. Sir Thomas Oliver said that while there were still too many accidents and too many workers made ill through causes connected with employment, recent changes in conditions of labour and in hours of work had tended greatly to the betterment of health among the working classes.

PROPOSAL FOR A GAELIC UNIVERSITY.

Considerable interest has recently been aroused in the Highlands of Scotland by proposals made by the lately founded American Iona Society to raise a sum of £2,000,000 for the establishment of a Gaelic University somewhere in the Highland area. It should be explained that there is no proposal to build this university on the island of Iona, the name being used simply to distinguish the American society. A considerable amount of criticism has been called forth. Provision is already made by the Education Act of 1918 for the teaching of Gaelic in all Gaelic-speaking areas, while in three of the four existing Scottish universities Gaelic is taught as a subject for graduation. No doubt these opportunities would be greatly helped if considerably supplemented by enlarging staffs in the department of Celtic languages, literature, and history, by scholarships and grants for the publication of textbooks and general literature bearing on the Highlands, and also for the better study of agriculture. On the other hand, it is pointed out that the establishment of such a university as is proposed would probably be a considerable embarrassment to the four existing universities. Attention is also drawn to the failure some years ago of the scheme proposed by Lord Leverhulme for the benefit of Lewis and Harris; on it over £1,000,000 was spent, but it failed because of the difficulty in recognizing the importance of certain peculiar local conditions and prejudices.

VICTORIA INFIRMARY, GLASGOW.

A new wing recently added to the Victoria Infirmary, Glasgow, and an extension of the nurses' home were opened, on February 26th, by the Right Hon. Sir John Gilmour, Secretary of State for Scotland. Mr. Robert Stewart,

convener of the buildings committee, who presided, said that the cost of the work would be £100,000, and the occupancy of the new wing would involve an additional £1,400 annual expenditure. Sir John Gilmour said that in Glasgow much more money was being spent upon remedial services than in English cities such as Birmingham. The reason appeared to be the conditions under which a great part of the population lived. One of the most appalling problems which the Government or municipalities had to face was the problem of improving the housing conditions of the country. When they got to the bottom of that root evil and improved it, the great pressure upon the hospitals was bound to grow less. In Glasgow 13 per cent. of the population occupied one-apartment houses, as compared with 5 per cent. in Edinburgh, 3 per cent. in Liverpool, and 1 per cent. in Manchester and Birmingham. In Glasgow 50 per cent. of the population lived in two-apartment houses, compared with 33 per cent. in Edinburgh, 7.5 per cent. in Liverpool, and 4 per cent. in Manchester and Birmingham. Glasgow's proportion of houses of five apartments and upwards, on the other hand, was only 8 per cent., whereas it was 20 per cent. in Edinburgh and over 50 per cent. in the English cities. Another condition in Glasgow was that 27 per cent. of the population were living in houses with more than three persons per room, while in Edinburgh this proportion was 12 per cent., in Liverpool 2 per cent., and in Manchester and Birmingham 1 per cent. Such conditions were bound to affect the health of the population of Glasgow, and must be steadily combated and improved. In Glasgow almost £3,500,000 per annum was being spent upon the health of the population. It called for the deepest reflection on the part of all those concerned, both nationally and municipally, to ascertain whether they were getting out of that immense sum the last word in efficiency and results. He believed there was room for further co-operation, co-ordination, and economy. He hesitated to speak dogmatically of the future, but he earnestly trusted that the voluntary principle and human interest in hospital administration would long be retained. It was most important that employers of labour and associations of workmen should be contributing to these institutions and taking an interest in this difficult matter. Only by co-operation and goodwill could the world progress. Sir John Gilmour then formally declared the new extension open. Mr. William Gray, Chairman of the Governors, said that with the new extension the hospital would have 360 beds. He referred to the new auxiliary hospital at Thorntonhall, of which the first portion, now in course of erection, would provide eighty beds, but the hospital was designed ultimately to accommodate 200 patients. Such auxiliary hospitals seemed to be the natural course to adopt in connexion with all infirmaries situated in cities.

EDINBURGH DENTAL SCHOOL.

The Edinburgh Dental Students' Society held its thirty-ninth annual dinner in Edinburgh on February 25th. Dr. John Orr, honorary president of the society, presided. Dr. Drinkwater, *in proposing* "The Dental Hospital and School," said that many of those present had known the school in its very early childhood, when it had been a very small institution. To-day, the Dental Hospital was full of vigour and energy, and known throughout the kingdom and the colonies. The great change in the hospital had practically taken place in one generation, largely owing to the enterprise of the present dean, Dr. Guy. In his reply, Dr. Guy remarked that it had early been perceived that the standard of examination should be raised, and when he became dean of the hospital and school he had realized that the staff should be thoroughly competent to teach both general and special subjects of the curriculum. This had now been provided, and worthy premises were just approaching completion.

GLASGOW STUDENTS AND CHARITIES.

The sum of £14,730, which became available as a result of the students' day held in Glasgow on January 15th, has been allocated as follows. The Lord Provost's Relief Fund receives £3,682, or 25 per cent. of the total; the Royal, Western, and Victoria Infirmaries and the Royal Hospital for Sick Children each receives £1,600, and the Royal Maternity Hospital £1,250, while the Royal and Western Infirmaries each receives £250 for installation of wireless apparatus. Other hospitals and medical institutions which benefit in sums between £150 and £600 are the Royal Samaritan Hospital for Women, Ear, Nose and Throat Hospital, Eye Infirmary, Royal Cancer Hospital, Elder Cottage Hospital (Govan), St. Andrew's Ambulance Association, the Lock Hospital, Glasgow District Nursing Association, and Incorporated Glasgow Dental Hospital. Smaller sums are also allocated to various homes and clinics.

EDINBURGH FOOT CLINIC.

The committee of the Edinburgh Foot Clinic has obtained St. Columba's School, Newington Road, Edinburgh, at a cost of £1,800. The clinic was opened a few years ago to provide treatment for minor disease and deformity of the feet at a moderate cost, and has been so largely used that its premises became inadequate. The new premises are expected to provide adequate facilities both for the practical work of the clinic and for teaching.

Ireland.

FREE STATE DEPARTMENT OF PUBLIC HEALTH.

THE first report of the Department of Local Government and Public Health, Irish Free State (1922-25), has been issued. Following the signing of the treaty with Southern Ireland on December 6th, 1921, the Local Government Board for Ireland and the Local Government Department of Dáil Eireann were co-ordinated by the Provisional Government, which later, on April 1st, 1922, established the Ministry known as the Ministry of Local Government. The Department of Local Government and Public Health, referred to above, was constituted under the Ministers and Secretaries Act, passed by the Oireachtas in April, 1924. It took over the powers of the Local Government Board for Ireland, the Inspectors of Lunatic Asylums in Ireland, the National Health Insurance Commission in Ireland, the Registrar-General for Ireland, the General Nursing Council, the Central Midwives Board, and other authorities. Its first report, now issued, which covers the period from April 1st, 1922, to March 31st, 1925, deals, among other topics, with public health, poor relief, and housing.

Progress has been made in restoring the conditions of normal health control. Typhus fever has almost disappeared as an incident of urban life. In urban districts in 1923-24 there were 3 cases only, and in 1924-25 one. In rural districts the corresponding figures were 59 and 49. The endemic area includes portions of the Atlantic seaboard where poverty and congestion persist. In a mountainous region to the north-west of Lismore a reported case was found to lead back, through a chain of cases either medically unattended or treated as enteric fever, to a fatal case of typhus six months previously. Of enteric fever in urban districts there were 43 cases in 1923-24 and 111 in 1924-25: the figures for rural districts in the two periods were 177 and 343. Outside of Galway, Kerry, and Tirconaill the disease did not assume prominence. Scavenging deficiencies, contaminated milk or ice-cream, and the use of shallow unprotected wells were demonstrated or suspected as sources of infection in various outbreaks. The incidence of diphtheria was higher in rural than in urban districts. Its prevalence in Newcastle West coincided with a defective water supply; in the city of Cork with overcrowding and faulty drainage. Scarlet fever, like diphtheria, was more frequent in the rural districts. There was one case of imported small-pox in November, 1923. The patient, who had travelled from London to Cobh, sought medical advice on arrival, and was found to be suffering from mild discrete small-pox. He was isolated in the local intercepting hospital, and persons who had been in contact with him were revaccinated. The disease did not spread. Local authorities, with few exceptions, are carrying out the Vaccination Acts, but the returns indicate that in certain areas

there has been a falling off in the number of children vaccinated.

The milk supply is supervised under powers conferred by the Dairies, Cowsheds, and Milkshops (Ireland) Order, 1908. The systematic bacteriological examination of milk samples is recommended in urban districts. The supervision of midwives is carried out by county and county borough councils under the Midwives (Ireland) Act, 1918. For maternity and child welfare work health visitors are provided.

The school medical service is in an early stage. In view of contemplated reforms in sanitary administration, which include the appointment of county medical officers for school and other purposes, county councils have not, in the meantime, been pressed to inaugurate school medical arrangements. County boroughs, on the other hand, have been urged to proceed. The school medical officer of Cork has inspected 11,296 children, of whom 8,166 were tested with Snellen's types. Of the children examined, 22.5 per cent. had defective eyes; 69.9 per cent. had defective teeth; 11.8 per cent. were classed as unclean, and 8 per cent. as ill nourished. Under the Education (Provision of Meals) Acts, 1914 to 1917, urban district councils are empowered to make arrangements for the provision of meals for school children.

Prior to 1925 the notification of tuberculosis was adoptive in Ireland in terms of Part I of the Tuberculosis Prevention (Ireland) Act, 1908, but with the coming into operation of the Local Government Act of 1925 it became compulsory throughout the Free State. Schemes for the prevention and treatment of tuberculosis under the Act mentioned and the National Insurance Act, 1911, have been approved in twenty-two counties and in Dublin and Waterford cities. Meath and Wicklow counties have partial schemes, dealing with insured persons and their dependants only. The approved sanatoriums are nine in number, with 815 beds. Part of the accommodation in 52 other institutions is available for surgical tuberculosis. At Cappagh, Finglas, county Dublin, there is an establishment of the Irish Sisters of Charity of 70 beds for the open-air treatment of surgical tuberculosis in children. Domiciliary treatment of tuberculosis is given in suitable cases, where home conditions permit.

By order of the Local Government Board in 1917, county borough councils in Ireland were declared to be authorities for the diagnosis and treatment of venereal disease. By the Public Health (Prevention and Treatment of Disease) (Ireland) Act, 1917, county councils, if they so desired, might also be declared to be authorities for the purpose. During the troubles which began in 1920, existing approved schemes under these provisions were centralized, and grants made direct to institutions and laboratories. In 1922 local authorities were urged to resume control of the work, special financial inducements being offered, but only Dublin and four counties sought for recognition. The normal State grant is 75 per cent. of the net annual cost to the rates. In 1924-25 the number of persons dealt with at treatment centres was 3,174; there were 25,991 out-patient attendances, and 7,951 days of residential treatment.

The report contains an interesting review of the history of poor relief in Ireland from 1634 onwards. Till 1921 the Irish Poor Law methods were based on the English model, in which the workhouse was the dominant feature, outdoor relief being given only under exceptional and exacting conditions. The respectable poor abhorred the workhouse as the haunt of the detrimental, and in 1921 steps began to be taken to introduce a system more conforming to the sentiments of the people. The small union areas, where the poor of every type were inevitably herded in one building, were done away with and replaced by the county unit. The county authorities promulgated schemes which were ratified under the Local Government (Temporary Provisions) Act of 1923. The principal points in these schemes were the abolition of relief in the Poor Law union workhouse, the centralization of management under the county authority, the provision of central county institutions, and the extension of outdoor relief. The cases of institutional relief, which were 26,791 in 1913-14, had fallen in 1924-25 to 18,113, while home assistance cases over the same period had risen from 14,663 to 21,650.

Up to 1919 the number of houses provided under the Housing of the Working Classes (Ireland) Acts was 8,700. In 1919 a survey of municipal housing needs was made, and it was estimated that the number of houses required was at least 46,416, of which one-half were for Dublin City. For three years little progress was made, but in 1922 the new Government set aside £1,000,000 for municipal housing, to be issued to municipal authorities under prescribed conditions in grants bearing the proportion of 2 to 1 to the total amount raised locally by housing rates and loans. Of the 94 local authorities concerned 71 adopted housing schemes, and over 2,000 houses have been erected. From the Housing (Ireland) Act, 1919, owing to disturbed conditions, only 74 dwellings had resulted, and from the Housing (Additional Powers) Acts (1919 and 1921) 348. The Housing (Building Facilities) Act, 1924, which was intended to revive the activities of private builders, appears to have attained this object, the sum of £300,000 available for grants under the Act being now on the point of exhaustion. For rural areas the Labourers (Ireland) Acts, 1883 to 1919, had produced 42,023 cottages. In Dublin the Commissioners, at the close of the period covered by this report, had preparations in hand for over 1,000 new houses.

The Roinn Rialtais Aitiúla Agus Sláinte Puibli, as its first report shows, is engaging the difficult problem of public health in Ireland in a courageous manner.

Correspondence.

TUBERCULIN IN THE PROPHYLAXIS AND TREATMENT OF TUBERCULOSIS.

SIR,—With reference to your article on this subject in the BRITISH MEDICAL JOURNAL of February 19th (p. 340), it is to be hoped that action on the lines you suggest will be taken. Having used tuberculin according to Dr. Camac Wilkinson's method since 1910, I am convinced that tuberculin given as he directs—namely, in gradually increasing doses till 1 c.cm. or over is reached, is at once the best and most economical method we possess at the moment in the treatment of tuberculous disease in the working classes. Repeated small doses of tuberculin, certainly in pulmonary cases, are in my experience a waste of time.

It is necessary to emphasize the social class, as comparisons of results obtained by other methods in the wealthier ranks of the population introduce a totally different set of circumstances well known to every hospital physician. As Dr. Camac Wilkinson tritely says,[1] "Tuberculin is not a cure for starvation."

Tuberculin in its present forms has undoubtedly its limitations. Unfortunately it is unsuitable for use in cases where no other known method of treatment, except perhaps occasionally artificial pneumothorax, is of any value.

We have a great deal to learn about it. The need for standardization of tuberculins as shown by Professor Dreyer[2] is one of the first essentials to any scientific investigation.

In my opinion the possible danger of tuberculin administration has been much exaggerated. Accidents happen in lung tuberculosis with or without treatment. I am by no means convinced that these accidents are more frequent after the use of tuberculin either in diagnosis or treatment.

I have published elsewhere[3] an article showing the marked difference in mortality rates between the tuberculin and the non-tuberculin treated cases of open pulmonary tuberculosis in dispensary practice at the end of seven to twelve years.

These figures were criticized[4] owing to the fact that the number of cases (83) treated with tuberculin was only about a quarter of the number of those not so treated. There was a very good reason for this,[5] as my work as medical officer of the Oxfordshire Association for the Prevention of Tuberculosis (1910-15) lay both in the city and county of Oxford. This fact presented an excellent control

[1] *The Tuberculin Dispensary for the Poor* (London: Nisbet and Co., Ltd.), p. 29.
[2] Dreyer and others: *Lancet*, 1924, ii, 1003; *ibid.*, 1926, i, 434.
[3] BRITISH MEDICAL JOURNAL, 1922, ii, 473.
[4] *Lancet*, 1923, ii, 524.
[5] *Ibid.*, 1923, ii, 853.

series (as far as this ever can be possible in lung tuberculosis) in populations of a ratio of about 1 to 4.

In the city of Oxford, with the lesser population, tuberculin treatment was possible, whereas in the country districts, miles from any dispensary, it was impracticable. The most important factor was the presence of tubercle bacilli in the sputum of every case. However desirable it may be to make the diagnosis of lung tuberculosis before the bacilli appear in the sputum, for scientific investigations as to the value of any line of treatment, only undoubted cases of the disease should be accepted.

Many statistics where the diagnosis has been made by, for example, "one medical man (the tuberculosis officer) after-taking into consideration the pathological and radiographic examination and the skilled opinion of his professional colleagues,"[6] are really useless as a guide to the value of any particular line of treatment, in the absence of the demonstration of the bacillus of Koch in the sputum. The general physician and, even more, the pathologist know how often the physical signs of lung tuberculosis can be simulated by other pulmonary conditions. Incidentally, whether notifications should not be restricted to cases yielding the tubercle bacillus is a matter worthy of discussion.

If the Medical Research Council or the Ministry of Health will devote the next five years to an investigation of the results of tuberculin dispensary treatment with Dr. Camac Wilkinson's ideas as a basis, I feel certain that a method will be evolved which will contribute to a large extent towards "relieving the country of some of its burdensome expenditure on tuberculosis."

At the same time, it would do something to ameliorate the tremendous pressure on sanatorium beds, which pressure, by the resultant delay, causes reasonably early cases to pass into stage two or even stage three, and this in its turn gives rise to the impression so common in the minds of the general practitioner of the markedly poor permanent results of institutional treatment in this country.—I am, etc.,

WILLIAM STOBIE,
Honorary Assistant Physician, Osler Pavilion for Tuberculosis, Radcliffe Infirmary, Oxford.

March 5th.

SIR,—Your interesting article on tuberculin in the treatment of tuberculosis (February 19th, p. 340) prompts me to write one more appeal to the medical profession to use tuberculin in massive doses in the one manner which Dr. Camac Wilkinson has so ably described in his well known book. This is not the place to go into details, but I am anxious to make the point that only by the administration of big doses can salvation be found. As one who for many years has given these big doses—that is to say, doses up to 1 c.cm. or 1.5 c.cm. of old tuberculin, etc.—I affirm that I have never seen any reaction which gave rise to a minute's anxiety, nor have I heard of such cases under the care of my colleagues.

For some years I was in charge of the tuberculin department of All Saints' Hospital for Genito-Urinary Diseases, and among the hundreds of cases there treated on the massive dose system I have never seen any ill result. These genito-urinary infections seem to be particularly suitable cases for tuberculin treatment. The marked improvement, even in advanced cases, is most gratifying. The Committee of the Ministry of Health, in its report on Dr. Camac Wilkinson's work, quoted him as saying that tuberculin was of little use in genito-urinary tuberculosis. Dr. Camac Wilkinson, on the contrary, urges its use, and agrees with me on its great value in such cases. The above mentioned report should be read along with Dr. Camac Wilkinson's rejoinder. No fair-minded reader could fail to be impressed with the triumphant vindication of the use of tuberculin in tuberculosis.

I would like to repeat once more the absolute necessity of attaining to the administration of the full doses of tuberculin. Timid doses in timid hands are futile.—I am, etc.,

ROLF CREASY.

London, W.1, March 5th.

CANCER AND TRAUMA.

SIR,—In your issue of January 29th (p. 216) Sir George Lenthal Cheatle asks "if anyone has met with the development of a tumour in a wound inflicted upon a combatant during the late war." He adds: "If mere traumatism can induce carcinoma or sarcoma it would be natural to expect examples from so great a wealth of material."

In a paper on "Local injury as a causative factor in bone sarcoma, with especial reference to the medico-legal aspects," published in the *International Journal of Medicine and Surgery* (vol. xxxix, Nos. 7 and 8, July and August, 1926), and also in the *Transactions* of the Southern Surgical Association, 1925, I reported a series of 360 cases of sarcoma of the long bones personally observed from 1890 to 1926. An analysis of this series showed a history of antecedent local injury in 181 cases; in 133, or about 70 per cent. of the cases, the tumour developed within the first six months of the injury, and in 38 per cent. of the cases it developed within the first month of the injury. In my conclusions I stated that, in sarcoma, especially in sarcoma of the long bones, there can no longer be the slightest question that a single local trauma, in the form of a bruise, a sprain, or a fracture, may be the direct exciting cause of the sarcoma.

Coming to the specific question raised by Sir George Lenthal Cheatle, I would say that in the paper just mentioned I quoted in abstract two cases of sarcoma developing at the site of local trauma as a result of injuries received during the late war, which cases had been under the care of Major Vitrac, and were reported by Dr. Faure at the meeting of the Society of Surgery of Paris, May 1st, 1918. In the first case a swelling developed in the thigh at the site of an injury sustained three months previously, caused by a fragment of shell. In the second case an artilleryman, while riding his horse, received a violent blow upon the anterior portion of the thigh by coming in sudden contact with a limb of a tree. About a year and a half later a swelling developed at the site of the injury. Faure regarded these two cases as proof that neoplasms can develop under the influence of local trauma. He states that while the mechanism may be obscure, it seems certain that the histological elements associated with reparation of tissue are susceptible, on exaggeration of their plasmatic role, of developing into a neoplasm. He does not believe it possible to deny the influence of trauma upon the development of tumours, as the number of definite examples is too high to admit any doubt.

Fortunately, I have further and more complete data, hitherto unpublished, kindly furnished me by Dr. John B. Walker, colonel in the American Expeditionary Force in France, in the world war. Since the war Dr. Walker has been engaged in a careful follow-up of cases of fracture observed in the soldiers of the American army. While his study is not yet complete, he has furnished me with the following information: Of 46 cases of sarcoma developing after recent fractures or gunshot wounds, and treated by amputation, 39 occurred in the femur or tibia (23 dead), 5 occurred in the humerus (2 dead), and 2 occurred in the radius or ulna (1 dead).

It would be interesting to know if any similar study has been made of the results of trauma received by the soldiers of the other armies engaged in the late war.—I am, etc.,

WILLIAM B. COLEY.

New York, Feb. 25th.

THE MODERN TREATMENT OF HERNIA.

SIR,—Mr. Geoffrey Keynes's paper on this subject (BRITISH MEDICAL JOURNAL, January 29th, 1927, p. 173) moves me to communicate two methods, differing in some essentials from those he advocates, which were described by me in a paper read before the Brighton and Sussex Medico-Chirurgical Society on June 3rd, 1926.

The method I have used for umbilical hernia is a combination of Mayo's and Gallie's technique. Mayo's operation is carried out to the point of overlapping the aponeurosis; the overlapping is done with living sutures. The upper stitch is a continuous mattress suture taking a single bite of the lower margin; the only point in

putting it in is to take care that each stitch is at a different level, so that a line of cleavage does not open up between the stitch-holes. When this is completed the same suture is continued back along the free margin, anchoring it to the aponeurosis beneath, and further stitches placed over the whole in zigzag fashion as in the operation for ventral hernia. The method of putting in the first stitches is indicated in the diagrams (Figs. 1 and 2).

I think the operation Mr. Geoffrey Keynes describes for femoral hernia is open to serious theoretical objection, if one accepts Gallie and le Mesurier's experimental results. They showed that, where two pieces of fibrous tissue were stitched together, union only occurred by weak areolar tissue, and that a permanent weak spot resulted; that observation, in fact, was the starting-point of their work. It seems hard to believe, in the face of their results, that the union achieved between the flap of rectus sheath and Cooper's ligament can be strong enough to withstand a severe strain.

The alternative method I have suggested, and used so far in three cases, is to block the opening of the crural canal with a living suture derived from the external oblique aponeurosis, much as Mr. Morrison describes in his operation for inguinal hernia (BRITISH MEDICAL JOURNAL,

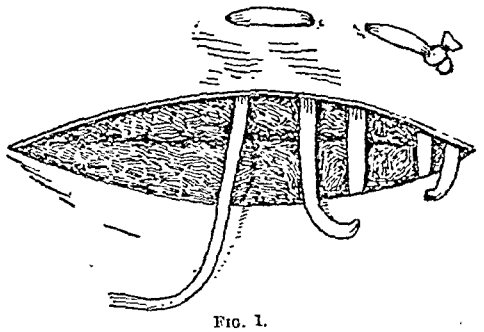

FIG. 1.

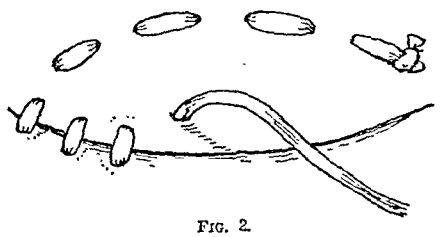

FIG. 2.

February 19th, p. 353). The inguinal approach is used; and may I say in passing that I have never found it necessary to clear the sac from below, as Mr. Keynes describes, there being no difficulty in dealing with the contents of the sac and pulling it up from above? When the sac is tied off, a strip of the external oblique aponeurosis about 1/4 in. wide is detached from the lower margin of the incision in it, and freed right down to the pubic spine. With a pair of Cleveland forceps this is brought through Poupart's ligament from without inwards, close to its attachment to the pubic spine, and is then woven across between Poupart's and Cooper's ligaments, completely closing the crural canal from above. If the skin incision is originally made extending to the level of the anterior superior spine, a strip 6 in. long can be got, which is ample to close the opening right out to the femoral vessels.

The method has not been in use long enough for any definite claim to be made for it, but it seems to close the canal thoroughly and permanently, and does not take much longer to perform than the Lotheisen operation as described in the textbooks.

May I, in conclusion, express my sense of our great indebtedness to Professor Gallie for the very important addition he has made to our methods of repair?—I am, etc.

Brighton, Feb. 19th. M. FITZMAURICE-KELLY.

WIRELESS MEDICAL CONSULTATIONS AT SEA.

SIR,—The letter from Dr. F. F. Bond on this subject, published in the JOURNAL for February 12th, raises many important questions and is most opportune at this moment. Why is it that, in Dr. Bond's words, "medical help at sea by wireless . . . has not at the present time the value it ought to and might have"? In attempting to answer this question, it is necessary to deal with three closely allied problems—the wireless consultation itself, the ship's medicine chest, and the medical manual which ships without a doctor on the high seas are supposed to carry. With regard to the wireless consultation, it is true that, as Dr. Bond writes, "if medical relief by wireless is to be of any real value it will have to be carefully considered and codified." This is not the case at present. Yet it is the opinion of experienced wireless operators that there would be no difficulty in arranging a simple international code. In a recent report to the League of Red Cross Societies, Lieutenant-Commander E. Anderberg of the Swedish Navy has stated that comparative little use has been made of the arrangement for wireless consultations between the Gothenburg General Hospital and ships at sea, and that the neglect of this service is to some extent due to the difficulty captains find in explaining the case to the hospital. To appreciate this difficulty, we have only to remember how inarticulate even well educated laymen often are when attempting to explain their symptoms in the undisturbed atmosphere of a consulting-room ashore. There is also the difficulty of the foreign languages—of a Portuguese captain trying to tell a Dutch doctor what his mate is suffering from. A standard questionary, which would give the captain hints as to the wording of his first message, and international standardization of certain medical phrases, would do much to simplify the task of all concerned. It is fortunate in this connexion that the present code of wireless signals is to be revised at an international conference in Washington next October.

As for the medicine chests carried by the ships of different nationalities, the same lack of international standardization is deplorably conspicuous; also the medicine chests of some countries betray many serious omissions and are far from up to date. It is obvious that if the aforementioned Dutch doctor is to recommend a drug he should know whether the Portuguese captain possesses it. Otherwise much time may be wasted, and much unnecessary exasperation generated. The medical manuals of the different countries show an even greater incongruity. Some are fairly complete, others are rather sketchy, while a few are little better than handbills. Clearly, it would facilitate the work of the doctor if he could refer, when giving advice by wireless, to chapter and verse in an international medical manual, or to a certain number which would be the same for the same subject in every national medical manual. Here, therefore, there is again a clear case for reform, for international co-operation.

I have discussed these defects in some detail in order to emphasize the importance of the work which has recently been started to remedy them. Thanks to the initiative and driving force of Dr. Harald Engelsen of the Norwegian Navy and medical adviser to the Norwegian Red Cross Society, the health and general welfare of the seaman was added in 1924 to the peace-time programme of the League of Red Cross Societies, of which the British Red Cross Society is a member. To solve the problem of the medley of medicine chests in the merchant fleets of the different countries, he secured the appointment of a committee of Norwegian experts to devise a medicine chest which might serve as a model for a standard international medicine chest. Further, with the co-operation of several of his colleagues, he published a large, freely illustrated medical manual which has already been authorized by the Norwegian Government for use on board Norwegian merchant ships. Another step has been the appointment by the League of Red Cross Societies of a standing committee on which, in addition to the League of Red Cross Societies, certain of the maritime national Red Cross Societies, the League of Nations, and the International Labour Office are represented. This committee, which met

for the first time on February 11th, is engaged on the three problems I have already discussed, and at its next session in October it will have before it, for examination as to its suitability for international use, a skeleton medical manual, based on Dr. Engelsen's manual, the whole of which has not yet been translated into English. It is so complete that there is little doubt as to its suitability to serve as a model for an international work. The same committee will investigate the problems of an international medicine chest and wireless code, and if it can frame a series of definite proposals to the powers that be, we may hope soon to see remedied some of those sins of omission which Dr. Bond has exposed.—I am, etc.,

CLAUDE LILLINGSTON.

League of Red Cross Societies,
Paris, March 4th.

SIR,—The questions raised by Dr. Bond in his letter (February 12th, p. 307) regarding "wireless calls for medical help at sea" have for some time been receiving consideration in official quarters, and in the new edition of the *Ship Captain's Medical Guide*, which will shortly be issued, a prominent place has been given to this subject. As the text of this book has not yet been sent to the printers, there is still time to incorporate any practicable suggestions, which will be given every consideration.—I am, etc.,

D. D. F. MACINTYRE, M.B., Ch.B., V.D.

Board of Trade Office, Southampton,
March 4th.

ARTIFICIAL PNEUMOTHORAX.

SIR,—The case of artificial pneumothorax described by Dr. Hudson in your issue of February 19th (p. 323) is a very interesting one, and shows that remarkable and immediate improvement may be obtained in apparently hopeless cases. Unfortunately, however, the ultimate result is not always satisfactory. When the lung is bound down by a broad adhesion (as shown in Fig. 4 of Dr. Hudson's case) there is always the possibility of a catastrophe.

I have in mind a case rather similar to that described by Dr. Hudson. When pneumothorax was begun the patient was more or less moribund, and had certainly seemed to have no more than two or three weeks to live. Within three months she was up and about and doing well. She kept well for over a year; and then, suddenly (a day or two *before* she was due to have a refill), she became very ill, and I found that she had developed a spontaneous pneumothorax, which eventually proved fatal.

This complication is comparatively rare. But I suggest that it is much more likely to occur when the base of the lung is affected, and when the adhesions are low down in the axillary line.—I am, etc.,

Kingussie, March 5th. FELIX SAVY.

A VACCINE FOR INFLUENZA.

SIR,—Dr. Carl Spengler is convinced that during the grippe pandemic of 1918 he detected in human sputum, blood, and excreta a micro-organism that during the previous thirty years he had never found in his continuous routine examinations of these substances. And with this new organism he noted new pathological symptoms in his patients. As his published writings concerning this micro-organism are practically unknown to English-speaking physicians, I would summarize as follows the more important facts he records.

This micro-organism is of variable morphology, but in the human body is most conspicuous as a somewhat ovoid, bipolar-staining bacillus. It is often found in the blood, and also inside body cells. It is pathogenic to animals. It is resistant to heat, being uninjured by a short exposure to 95° C., yet grows freely at room temperatures as low as 24° C., and can survive prolonged freezing. It grows on ordinary media, and in peptone water; it also proliferates freely in slightly alkaline human urine, especially if a trace of albumin is present. It proliferates in sewage-polluted water at as low a temperature as 12° C. In sputum and urine it tends to kill out other bacilli (in sputum the tubercle bacilli). To get a pure culture from urine Dr. Spengler heats the urine for a moment to 90° C., adds 5 to 10 per cent. peptone, and incubates. To isolate it from blood or sputum he inoculates into peptone water.

In the winter of 1918-19, out of 100 consecutive patients from all parts of Europe, coming to him for various complaints, he detected this organism in the freshly voided urine of 96. In 27 the urine was alkaline, and in 45 it contained albumin. He looks upon the alkalinity of the reaction and the presence of albumin as due to this organism. He finds that the afebrile carriers are cured by a few injections of the vaccine made from this organism. When fever is present it is rapidly reduced by treatment with the antibodies obtained from the blood of animals immunized with this vaccine. The vaccine treatment is also prophylactic.

Dr. Spengler does not discuss the probability of animals also being carriers. Nor does he deal with the possibilities of extensive air-borne infection from desiccation of contaminated excreta and sewage effluent. The following are some references to his publications on the subject:

Ueber die Spanische Grippe, von Dr. Carl Spengler (Ernst Bircher, Bern, 1919). *Die "Spanische Grippe" und ihre Bekämpfung*, von Dr. Carl Spengler (Ernst Bircher, Bern, 1919). "Uber die Darstellbarkeit polgefärbter (pestbazillenähnlicher) Stäbchen bei verschiedenen Bakterienarten," von Dr. Emil Epstein, *Archiv für Hygiene*, Bd. 90, München.

—I am, etc.,

Davos, Feb. 25th. J. BARCROFT ANDERSON, M.D.

GASTRIC HAEMORRHAGE.

SIR,—Dr. Charles Miller, in his lecture on gastric haemorrhage, makes one statement which I feel should not be allowed to pass without criticism. Under the heading of treatment (p. 413) he says: "On no account should transfusion be performed, unless a surgeon is opening the abdomen." I do not wish to go to the other extreme by implying that every patient should be transfused after a gastric haemorrhage, but I wish to state my belief, based on experience, that many patients will be exposed to a serious and unnecessary risk if Dr. Miller's advice be always followed. He himself states a few lines above that "we wish to improve the patient's condition, stop the haemorrhage, and prevent its recurrence." It will be found in practice that all these desirable objects tend to be attained by a fairly free use of transfusion apart from the question of surgical treatment. Dr. Miller's view is perhaps based on the idea that transfusion will encourage haemorrhage by producing too great a rise in the blood pressure. This is not found to occur in practice, whereas many a patient will come very near to death, and some will die, if transfusion is withheld until a second or third haemorrhage has taken place. The question was fully considered at the Annual Meeting of the British Medical Association in Nottingham last year (BRITISH MEDICAL JOURNAL, November 27th, 1926), so that I need not repeat the arguments here.—I am, etc.,

London, W.1, March 5th. GEOFFREY KEYNES.

AFTER-TREATMENT OF MASTOID OPERATIONS.

SIR,—May I, after several years' experience, endorse all Mr. A. J. Wright, in the JOURNAL of February 26th (p. 375), has said as to the advantages of paraffin in the after-treatment of mastoid operations, whether the ordinary or "conservative" radical? They are: painless introduction and removal of the paraffin, rapid diminution of discharge, rapid and even epithelialization. The resulting cavity is excellent. The paraffin can be scraped into a teaspoon, warmed over a spirit lamp, and, after being tested as to temperature and when near solidifying point, poured into the ear. There is no need of any special "basket" dressing such as suggested by Mosher; any difficulty on removal is overcome by a warm probe. A great aid in healing is the momentary insertion of a needle-shaped electro-cautery point down the Eustachian tube as far as the isthmus. This sterilizes and seals the tube in almost every case; properly applied it is without risk. It is done after the bone operation is finished, and before the plastic. —I am, etc.,

Glasgow, March 1st. JAMES ADAM, M.A., M.D.

PRESCRIPTIONS UNDER THE DANGEROUS DRUGS ACT.

SIR,—The Dangerous Drugs Act may have its advantages; it certainly has its disadvantages.

Having sent a patient to a South Coast town for a rest, I received a request from her for some help for insomnia. I gave a prescription with all the precautions rendered necessary under the Act.

On my patient's return home I inquired as to the success of the prescription. I was told that the chemist could not make it up as he could not prove that the signature was mine. He suggested—as a friend—that my patient should get the prescription countersigned by a local practitioner.

Further inquiry on my part from the chemist elicited the fact that a chemist had been fined £100 for making up a prescription which turned out to be a forgery, and the Retail Pharmacists' Union has issued a warning against dispensing any D.D.A. prescription unless the chemist can swear to the signature!

I am afraid that if the law compelled us, like the bookmakers, to have our likenesses stuck on our prescriptions it would not meet the case! The position is farcical.—I am, etc.,

Crawley, Sussex, Feb. 20th. SIDNEY MATTHEWS, J.P.

*** In response to an inquiry we are informed that the Retail Pharmacists' Union and Chemists' Defence Association, Ltd., has not issued any such general warning as Dr. Matthews quotes. "We have, however," the secretary states, "from time to time informed correspondents that as chemists are committing offences under the D.D.A. if they dispense forged prescriptions, they should not accept such prescriptions if they do not know the doctor's writing and are unable, for any reason, to verify the genuineness of the prescription."

PUERPERAL SEPSIS.

SIR,—I wish the East End Mothers' Lying-in Home could claim the immunity from sepsis which Dr. Cook (March 5th, p. 444) kindly puts to its credit, but as so far no clinical report has been issued, his figures must have been taken from the general report, which only deals with births and deaths.

A clinical report giving details of the work for the last two years is now in the printer's hands, and when it is published it will be seen that the ideal, for which we are all striving, has not yet been attained by this hospital.—I am, etc.,

W. H. F. OXLEY, M.R.C.S., L.R.C.P.,
Honorary Medical Officer, East End Mothers' Lying-in Home.

March 7th.

Obituary.

FRANCIS SHILLINGTON SCALES, M.A., M.D.,

Lecturer in Medical Radiology and Electrology, University of Cambridge.

WE regret to announce the death, on February 28th, of Dr. F. Shillington Scales, after a long illness, at the age of 61. He received his education at Jesus College, Cambridge, and the Middlesex Hospital. He graduated M.B., B.Ch.Camb. in 1909, and proceeded M.D. in 1912, being awarded the University Raymond Horton-Smith prize for his thesis. He early became distinguished for his contributions to microscopy, writing papers in various journals, publishing a book entitled *Elementary Microscopy* in 1905, and another on *Practical Microscopy* in 1909; a third edition of this last was issued in 1926. He was a Fellow of the Royal Microscopical Society, in which he had held office as curator, honorary secretary, and vice-president. Another post which he held was that of lecturer in microscopy at the Westminster Hospital. In 1912 he published an account of the electro-cardiogram as an aid to diagnosis, and afterwards turned his attention to radiology and medical electrology. He took a very active part in instituting the diploma in medical radiology and electrology at Cambridge in 1919; he was secretary to the University Committee concerned, and was examiner for the diploma until his death. He was lecturer in medical radiology and electrology in the University, and physician-in-charge of the *x*-ray and electrical department at Addenbrooke's Hospital. He was a member of the council of the British Association of Radiology and Physiotherapy and of the British Institute of Radiology.

Dr. Shillington Scales had long been a member of the British Medical Association. He was Honorary Secretary of the Section of Electro-Therapeutics at the Annual Meeting at Cambridge in 1920, and had been appointed vice-president of the Section of Radiology for the forthcoming *Edinburgh Meeting of 1927.*

Dr. S. GILBERT SCOTT, radiologist to the London Hospital, has in response to our request sent us the following tribute to Dr. Scales's work.

Radiologists in London instinctively connect the late Dr. F. Shillington Scales's name with the Cambridge diploma in radiology. His unbounded enthusiasm in all educational matters affecting radiology and kindred subjects was one of the outstanding features of his life. This enthusiasm played an important part in the establishment of the diploma in radiology and electrology at Cambridge. The intense earnestness he threw into the teaching of candidates for this diploma had without doubt put a considerable strain for some years on his physical powers, leaving him with little or no reserve when it was required to fight his last illness. The fact that he continued his teaching during his illness, with his men grouped around his bed, illustrates this trait in his character. To those who did not know him well his manner may have appeared somewhat dogmatic and brusque when discussing radiological subjects. This was but an outward evidence of his keenness; his work came before everything. His loss will be especially felt by the teaching radiologists in London. Even those who did not see eye to eye with him appreciated his loyalty, enthusiasm, and valuable work in connexion with Cambridge.

To "W. E. D." we are indebted for the following:

Dr. Shillington Scales, whose early loss we deplore, was well known in Cambridge. His professional life came to be devoted to radiology. He early recognized the dangers of allowing this new and important branch of medicine to pass into the hands of practitioners without special training; and he, with other pioneers of the subject, determined to start a diploma. Dr. Scales certainly took a great part in placing the teaching of the science of radiology on its present sure footing by the interest he showed in inaugurating the Cambridge diploma. His teaching, both at the medical school and at Addenbrooke's Hospital, was popular: no trouble was too great to take in explaining a difficult point. He showed much ingenuity also in using home-made apparatus, which he applied to the needs of the laboratory. In his own department he was widely read, and kept a complete list of abstracts of all important papers published in England and abroad. Dr. Scales had an extensive private practice in radiology, and endeared himself to hospital and private patients alike. He had a vigorous and energetic temperament which carried him through many difficulties; laziness was a condition unknown to him, and this was shown in his last illness when he insisted on conducting his classes to within a day or two of his death. Dr. Shillington Scales has left a permanent mark on Cambridge, in that he had much to do with the initiation of the radiology diploma: his post of university lecturer was the first of its kind, and he was the first honorary physician in charge of a radiology department at the hospital. He must always be remembered by his pioneer work in raising the status of radiology. He leaves a wife and two daughters.

Dr. ROBERT JOHN HILLIER died at his house in Sheffield on February 22nd. He was the eldest son of Dr. James Thomas Hillier, who practised at Ramsgate. He was born in 1869, was educated at Epsom College and St. Bartholomew's Hospital, and took the diplomas of M.R.C.S.Eng. and L.R.C.P.Lond. in 1891. From 1891 to 1895 he was house-surgeon at the West Ham Hospital. Afterwards he practised at St. Albans, Halifax, Stoke-on-Trent, and finally settled in Sheffield in 1910. Though

engaged in general practice he gave special attention to the administration of anaesthetics. His characteristic thoroughness, care, and accuracy led to his becoming so safe and reliable an anaesthetist that his services were much sought after, especially in difficult cases. He was a perfect exponent of the Shipway method of giving ether, which, in his hands, appeared to banish shock even after prolonged and difficult abdominal operations. From 1920 he was senior anaesthetist to the Jessop Hospital for Women, and it was in the operating theatre there that, on January 4th, he showed signs of cerebral thrombosis which gradually spread during the following six weeks. Dr. Hillier's unselfish loyalty and great capability were highly valued, and he will be greatly missed by his fellow members of the Sheffield Division of the British Medical Association. His outside interests were reading, especially history, and photography; he was an honorary member of the East Herts Archaeological Society, and a life member of the St. Albans and Herts Architectural and Archaeological Society.

We regret to record the death, on March 1st, from pneumonia, at the age of 56, of Dr. HERBERT MAYRIS SYLVESTER, who had practised for many years at Leiston in Suffolk. He was the seventh son of the late Samuel Augustus Sylvester of Tonbridge, and from Tonbridge School went, in 1888, to St. Bartholomew's Hospital, where two of his elder brothers—Lieut.-Colonel G. H. Sylvester, F.R.C.S., R.A.M.C.(ret.), and another who died early—had been students. He obtained the M.R.C.S. and L.R.C.P. diplomas in 1892, and country general practice almost at once claimed him. He settled in Leiston, a few miles from Saxmundham, and soon became the trusted friend and adviser in many homes throughout the town and the scattered villages around it. He was medical officer of health for the Leiston Urban District, and medical officer and public vaccinator for the Blything Union, and his duties as certifying factory surgeon brought him into close touch with the men engaged in the local ironworks, where agricultural machinery and implements are made. Dr. Sylvester had been a member of the British Medical Association for thirty-five years, and although he took little part in professional affairs beyond his own area, his sterling character and devotion to duty won him the regard of all his colleagues in the South Suffolk Division.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on March 5th Dr. G. S. Graham-Smith, F.R.S., was appointed a manager of the Nita King Research Fund, in succession to the late Mr. T. S. P. Strangeways, and Mr. J. Duncan White was appointed to carry on for the remainder of the term the teaching work of the late Dr. Shillington Scales in medical radiology and electrology.

The following medical degrees were conferred:

M.D.—W. N. Goldsmith.
M.B., B.CHIR.—B. E. Ahrens, D. G. Shields, W. A. Bourne, H. E. Nourse.
B.CHIR.—R. W. B. Ellis, H. L. Wilson.

UNIVERSITY OF LONDON.

SENATORIAL ELECTION.

MR. WALTER G. SPENCER, consulting surgeon to Westminster Hospital, has offered himself for election to the Senate as a medical member of Convocation; he has the support of the University of London Graduates' Association. He was, until last year, a member of the Council of the Royal College of Surgeons of England, and one of its vice-presidents; he is Honorary Librarian to the British Medical Association. As mentioned last week, Mr. W. McAdam Eccles, surgeon to St. Bartholomew's Hospital, is also a candidate for the vacancy, which is created by the expiration of the term of office of Dr. R. A. Young, who does not intend to offer himself for re-election. The election will take place on May 10th, but voting papers will be circulated to members of Convocation before that date.

UNIVERSITY OF CAPETOWN.

THE following candidates have been admitted to the degree of M.B., Ch.B.:

M. Abel, A. G. Bester, C. C. Brown, E. L. Dirmeik, Phyllis A. Don, Emily C. Greenfield, S. A. Lange, G. M. Malan, I. D. Miller, I. V. Rogoff, J. Siebert, J. G. Siebert, Dorothy G. Vadas, I. J. M. van Niekerk, A. G. W. von During, Rose Weinberg.

Medico-Legal.

HUME-SPRY *v.* SMITH AND WATSON.

Alleged Wrongful Certification under the Lunacy Act.

IN the King's Bench Division, on March 1st, Mr. Justice McCardie and a special jury began the hearing of an action in which a civil servant, Mr. Frederick Hume-Spry, claimed damages against Dr. Robert Percy Smith of Queen Anne Street, London, and Dr. A. H. Watson of Salisbury, for alleged negligence in certifying him insane.

Mr. Hume-Spry was certified in March, 1923, and was detained in an asylum until December, 1923, when he was certified by other medical men as sane. The defendants pleaded the protection of Section 330 of the Lunacy Act, 1890, having acted in good faith and with reasonable care.

Sir Henry Maddocks, K.C., in the course of his opening speech for the plaintiff, said Mr. Hume-Spry was now employed in the Probate Registry at Somerset House. In March, 1923, a petition was presented by his wife for an order for his reception, as being a person of unsound mind, at the Old Manor House, Salisbury. On March 13th, 1923, the plaintiff was examined at an officers' hospital at Latchmere, Ham Common, by Dr. Percy Smith, one of the defendants, who gave a certificate that he was of unsound mind and a proper person to be detained under care and treatment. In that certificate Dr. Smith stated that Mr. Hume-Spry had a fixed delusion that Dr. Woods, who was in charge of the Palace Green Hospital, Kensington (a hospital for neurasthenic and shell-shock patients under the Ministry of Pensions in which Mr. Hume-Spry had been a patient in 1920 and 1921), was taking his wife out to dinner and visiting her flat; further, that Mrs. Hume-Spry "tells me that he has had a fixed delusion about the medical officer and herself for about two years. He thinks all doctors are mad. One night a few weeks ago she found that he had turned on the gas over her head, and refused to let her out of the room. Last night he said it was a plot of the Ministry of Pensions and put a carving knife to his neck." On March 17th, 1923, after Mr. Hume-Spry had been detained in the asylum, Dr. Watson, the other defendant, was called in, and he gave a certificate that Mr. Hume-Spry was of unsound mind, in the course of which he wrote: "He states that he has had some silly ideas and also that he has been 'swinging the lead' for the purpose of getting a permanent pension. He declares that his wife backed him up in persuading people he was peculiar, and denies altogether that he attempted to take his life." On these certificates a reception order was made by a magistrate, and Mr. Hume-Spry remained at the Old Manor House until December, 1923, when he was certified by other doctors (Sir James Purves-Stewart, Dr. Risien Russell, and Dr. Hughes) as being perfectly sane. In consequence he outstayed his leave, went to a solicitor, and refused to go back to the asylum. Counsel urged that it was not entirely unknown that a wife should be unfaithful to her husband, nor that such a wife might wish to get rid of her husband so that he should no longer interfere with what she wished to do. When, in these cases, the wife was the person who was moving to get her husband put away the very greatest care was necessary before sending him to a lunatic asylum. There was, in fact, no delusion at all, for it was true that his wife had been unfaithful to him. He never tried to murder her, or to commit suicide, and these facts would have appeared if the doctors had made proper inquiries.

The plaintiff, in evidence, amplified in great detail the opening statement of his counsel, and was cross-examined at equal length by Mr. A. Neilson, K.C., for the defendants. In the course of this cross-examination Mr. Hume-Spry agreed that while at Palace Green Hospital his wife visited him every day, and that he told Dr. Macnamara, the visiting neurologist from the Ministry of Pensions, that he had nightmares. He denied, however, that he also said he had promptings toward suicide, or that he felt that the right thing to do was to die. He denied that he suggested to his wife that she should get Dr. Woods to compromise himself with her. He denied that his outbursts at a convalescent home at Dolgelly were such that Dr. Stevens formed the view that he was not a fit patient for his hospital, which was staffed by V.A.D. nurses. He denied that a letter of apology he wrote to Dr. Woods while at Palace Green Hospital was written of his own accord. Questioned about breaking into his wife's flat in Marylebone at 1.30 one morning, the plaintiff admitted breaking the glass because he could not make his wife hear the bell. His wife's mother was there, but he did not raise his arm to strike her, nor shout "Where is that man?" He had been told by an orderly at Palace Green Hospital that a man was visiting his wife's flat. Plaintiff denied saying to his wife's mother that he thought of furnishing a flat in Oxford Street for his wife, who could "easily get some man to pay the rent." After answering this question the plaintiff asked the judge how long had he got to stand these damned insults. To this Mr. Justice McCardie replied: "You have made many accusations yourself, and counsel is quite entitled to cross-examine you fully." Plaintiff said it was at Malmesbury that his wife confessed to him that Dr. Woods had seduced her. He was not particularly shocked as he had known it subconsciously; it was more like a relief. He continued to live with her afterwards. She wrote the confession later. The confession was afterwards read by Dr. Macnamara, Mr. Francis, a Mrs. Holland (since dead), a Mrs. Brennan, her daughter, and another person he could not now remember. Dr. Macnamara looked at it three or four minutes, and then said he could not read it. When he (plaintiff) took it to Mr. Francis (his wife's solicitor) the chief clerk (Mr. Collins), in the absence of

Mr. Francis, read it carefully. Later Mr. Francis read it and said that he believed it all, and that it was very sad, but that he could not advise any action being taken. He (plaintiff) said he did not want to take any action, but it was in case of any future trouble about certification. His wife and himself were on excellent terms at that time. He denied that he gave a sealed envelope to Mr. Collins to hand to Mr. Francis, or that he again went to the office before Mr. Francis returned and opened the envelope in Mr. Collins's presence. Answering the judge, the plaintiff said that Mrs. Brennan was in America and that he was not calling anyone to say he or she had seen the confession. The plaintiff admitted going to see a Dr. O'Donovan in 1921 and that Dr. O'Donovan turned him out of the room because he made accusations against Mrs. Hume-Spry and Dr. Woods. He declared that whilst some of the many doctors he saw might have acted honestly, some did not. He admitted writing on a piece of paper *attached to his diary*: "*In view of the insufferable state of* affairs in my home I am proceeding to London to-morrow, January 1st, with the intent and determination of committing adultery with a woman, the particulars of which will be given to my wife in order that a divorce may be granted to her." That was dated December 30th, 1922. Counsel said it was obviously written on December 31st, and asked plaintiff whether he was sitting at the foot of his wife's bed when she woke up during the night on December 31st. Plaintiff denied that he was, or that the gas was turned on, or that he refused to allow his wife to leave the room. Asked why the Ministry of Pensions headquarters should conspire to put him away, plaintiff replied, "Because I had made a charge against one of their doctors." He denied that on March 12th, 1923, he came behind his wife and put a bread knife to her throat, or that he was found soon after on one knee with the same knife at his own throat. His wife did not knock the knife out of his hand.

Counsel: Your case is that your wife was trying to secure your certification?—Yes, under Dr. Woods's influence.

Counsel: Do you suggest that Dr. Woods was influencing the other doctors who saw you?—I do not say that.

Counsel: Do you suggest that Dr. Woods influenced Dr. Smith?—I do not say that.

Do you think so?—Possibly.

He admitted he had probably written to the Ministry a letter in which he accused his wife of living under someone else's protection. He had in mind at the time either Dr. Woods, or Dr. Chetham-Strode, or Dr. Stodart-Walker.

Do you now say that these accusations which you have made against various persons are true?—I have already told you that I am here because I believe that they are true.

He admitted writing to Dr. Woods on April 23rd, 1923, a letter in which he said he had been entirely misled as to Dr. Woods's relations with his wife and withdrew his other accusations. Plaintiff said he believed what he wrote to be true at the time, but he wrote it in the foulest surroundings a man could be in, and he did not think it fair to question him on it.

If you believed that letter why do you now maintain these allegations against Dr. Woods?—I base my allegations against Dr. Woods on what my wife told me.

Has any evidence come to you since April 23rd, 1923, which makes you recant what you said in the letter?—No.

At a later stage in his cross-examination plaintiff agreed that in April, 1924, two writs were issued, one of which was the writ in this action, while in the other damages were claimed against Dr. Stodart-Walker, Dr. Woods, Mrs. Hume-Spry, and Dr. Martin for conspiring to secure his certification as insane and to deprive him of his liberty.

Sir Henry Maddocks: That action is still alive.

Mr. Neilson (to plaintiff): You do not hesitate to make charges with regard to these matters against anybody you can?—I do not. I have had to.

After short re-examination the plaintiff left the witness-box on the fourth day of the trial.

Dr. T. S. A. Orr of Welbeck Street, London, in evidence, said that Mr. Hume-Spry came to him in January, 1924, and, after five or six interviews, witness gave the plaintiff a certificate that he could find no evidence of delusion or hallucination. The plaintiff was not unduly depressed or elated, and in his opinion was sane. Mr. Hume-Spry had been certified mainly because of an alleged delusion that his wife was unfaithful to him—the plaintiff had noticed a change of his wife's affections while he was at Palace Green Hospital and had come to the conclusion that she was too friendly with Dr. Woods. Witness said he saw Mr. Hume-Spry's solicitor, Mr. Peters, and asked him if he had seen any letters shown him by Mr. Hume-Spry that might support the opinion of the plaintiff that his wife had been unfaithful to him. Mr. Peters told him he had. Witness added that these letters impressed him at the time as being such as might make the plaintiff think his wife had been too friendly with a man, or men. In reply to counsel's question, "If they were delusions then is it obvious that they are still delusions?" Dr. Orr replied, "They are as much delusions to-day as they were then." Witness thought Mr. Hume-Spry a particularly astute and intelligent man. The fact that the plaintiff said he still loved his wife, but that he would do his best to damn her, would not necessarily mean insanity.

Cross-examined, Dr. Orr said he was at the Ministry of Pensions up to December, 1924, but he was practising all the time. He agreed that Dr. Percy Smith had a high reputation as a specialist in mental diseases.

Mr. Neilson: Do you accuse Dr. Smith of bad faith in this case?—I thought there was a difficulty in getting a definition of bad faith.

Mr. Justice McCardie: Answer the question on your view of the meaning of the phrase. Do you suggest, on what you have seen, heard, and know, that in this case there was bad faith by Dr. Smith?—Yes.

Mr. Neilson: With full se[illegible] lved in your answer as a professional man [illegible] man?—Yes.

What do you mean by bad [illegible] matter where one should be fair.

Do you mean intentional unfairness on Dr. Smith's part towards the patient whom he was *examining*?—*No. I would not go so far as to* say that.

Mr. Justice McCardie: What you say is unconscious prejudice and nothing more?—That is so.

In reply to further questions Dr. Orr agreed that he did not see Mr. Hume-Spry for over ten months after Dr. Percy Smith had seen him, and took no pains to verify the statements he made. He did not go to see Mrs. Hume-Spry or Dr. Smith and Dr. Oliver, nor did he make any inquiry from Dr. Woods or the Ministry of Pensions.

Mr. Hume-Spry, recalled, was further cross-examined and was still in the witness-box when the court adjourned on Tuesday afternoon, March 8th.

The defendants, Dr. Percy Smith and Dr. A. H. Watson, are both members of the Medical Defence Union, and Mr. Neilson and Mr. Dickens are the counsel appearing for them on the instructions of Messrs. Hempsons, acting as solicitors to the Union.

HARNETT *v.* FISHER IN THE HOUSE OF LORDS.

THE House of Lords, on February 28th, March 1st and 3rd, heard the arguments in the appeal of Mr. William Smart Harnett, farmer and fruit grower of *Springfield*, Newington, near Sittingbourne, Kent, against an order of the Court of Appeal dismissing his appeal from the judgement of Mr. Justice Horridge in an action in which Mr. Harnett sued Dr. Holdrich Fisher of Sittingbourne, a duly qualified medical man, for negligence in signing a medical certificate under the Lunacy Act, 1890, to the effect that the appellant was a lunatic and a proper person to be detained in an asylum.

The facts in the action against Dr. Fisher were the same as those in the action against Dr. Adam and Dr. Bond, the hearings and the appeals consequent thereon being fully reported in previous issues of the BRITISH MEDICAL JOURNAL.

The certificate was signed on November 10th, 1912, and the writ in the action Harnett *v.* Fisher was issued on May 31st, 1922, the appellant pleading that he was unable to bring his action earlier because he was detained in asylums as the result of the respondent's negligence until October 15th, 1921. The respondent pleaded the protection of Section 330 of the Lunacy Act, having acted in good faith and with reasonable care; and, further, pleaded that the action was barred by the Statute of Limitations (21 Jac. I, c. 6). The special jury's answers to the questions *of the trial jury were as follows*:

(1) Was Mr. Harnett of unsound mind on November 10th, 1912, when he was certified by Dr. Fisher?—No.
(2) Did Dr. Fisher act with reasonable care in certifying him?—No.
(3) Damages?—£500.

Mr. Justice Horridge, however, accepted the argument of the respondent that the jury having found that Mr. Harnett was a sane man on November 10th, 1912, his right of action was barred by the Statute of Limitations, and entered judgement for the respondent accordingly, this decision on the law being affirmed by the Court of Appeal, consisting of the Master of the Rolls, Lord Justice Warrington, and Lord Justice Scrutton.

The appeal to the House of Lords was heard by Lords Sumner, Atkinson, Wrenbury, Carson, and Blanesburgh.

The appellant, who argued his case in person, contended that the plea that his action was barred by the Statute of Limitations failed on several grounds. First, the question of *non compos mentis* being one of status, was a matter of law rather than one of fact. In fact he was sane, but in law he was a lunatic, and it followed that as he sufferec [illegible] g to lunacy so he was entitled to all th[illegible] is the respondent had certified him (the [illegible] respondent was surely estopped from alleging now that he was sane. Thirdly, restraint as a lunatic prevented him from bringing his action during the period from November 10th, 1912, to October 15th, 1921. Section 82 of the Lunacy Act, 1890, showed that the Legislature did not contemplate that a person detained as a lunatic could bring an action during detention. *Time would not run* against him until he knew the facts, and he never saw the certificate drawn up by the respondent until he was free. The House would be slow to apply the statute to defeat an honest claim (Boatwright *v.* Boatwright, L.R. 17 Eq., 71, 74).

Mr. A. Neilson, K.C. (with him Mr. T. Carthew), for the respondent, said that the question turned on the construction of the Statute of Limitations.

Lord Blanesburgh intimated that the Statute had nothing to do with the case, and that the real question was whether the respondent was protected by the Public Authorities Protection Act, 1893. Section 331 of the Lunacy Act, 1890, prescribed a special period of limitation in the case of an action brought under Section 330, and that period was one year after release. On that hypothesis, the appellant's action was not out of time, as it was brought seven months after he regained his liberty. Then, though Section 331 was repealed by the Public Authorities Protection Act, 1893, there was a question raised in *Halsbury's Laws of England*, vol. xix, para. 365, as to the extent of that repeal—whether, despite the later Act, Section 331 would stand in an action brought

against a private person. Was Dr. Fisher a private person within the meaning of that section?

Mr. Neilson, continuing his argument on the footing that leave would be given to amend the pleadings—the Public Authorities Protection Act having to be specially pleaded to be relied upon—urged that Dr. Fisher was precisely within the ambit of the Public Authorities Protection Act, the act of certification being done in pursuance of an Act of Parliament. Accordingly Mr. Harnett, in bringing his action seven months after his release, was a month out of time.

Mr. Harnett having replied, the House reserved judgement.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week discussed the Army and Air Estimates, the dispatch of troops to China, unemployment, and several small bills.

The Parliamentary Medical Committee arranged that at its meeting on March 9th it would confer with representatives of the British Medical Association regarding the Dogs' Protection Bill.

The text of the Midwives and Maternity Homes Bill was published on March 8th. Introduced by Mr. Barclay Harvey, and supported by Sir George Berry and Dr. Fremantle among others, this bill is designed to extend to Scotland the chief provisions of the legislation recently passed for the control of midwives and maternity homes in England. The bill has the goodwill of the Scottish Board of Health.

The group of members which, under Sir Leslie Scott, has been revising the Mental Deficiency Bill completed its work on March 8th, and the bill has been printed. The definition of mental deficiency and some administrative proposals have been so revised that the friends of the bill believe Parliament will treat it practically as an agreed measure after its second reading, which is down for March 18th.

In consequence of his retirement from the Labour party, which was announced last week, Dr. Haden Guest has decided to vacate his seat for North Southwark, which he has held since 1923. He will offer himself for re-election as an independent candidate.

Experiments on Animals.

On March 8th Dr. Fremantle asked the Home Secretary whether he had received from his inspectors under the Cruelty to Animals Acts any reports during the last five years indicating either demonstrations before classes of students or painful experiments of a prolonged and agonizing nature on dogs or other animals; and, if so, what action had been taken, and with what result. Captain Hacking (Under Secretary to the Home Office) replied that no such experiments would be permitted, and there was no evidence whatever that any had been made. All experiments before students were required to be performed under anaesthetics, and the animal must be killed before it recovered consciousness. As regards other experiments, all holders of licences who had certificates either dispensing with the requirements to use anaesthetics or permitting the animals to recover from the preliminary operation under anaesthetics were subject in respect of every experiment to a special condition known as the "pain condition." The terms of this condition were printed in the report which was laid yearly before the House of Commons, and were such as to render "experiments of a prolonged and agonizing nature" impossible. For many years past the inspectors under the Act had not found any instance of an infringement of this condition. If an inspector did observe any animal to be suffering considerable pain he would at once order it to be killed.

Dr. Fremantle asked whether Captain Hacking was aware that these specific statements, which he had just declared to be untrue, were being publicly circulated by the National Canine Defence League, and were said to have resulted in a very large number of subscriptions. He asked whether Captain Hacking could do anything to prevent such misleading statements. Captain Hacking said he knew that many things were said by many organizations that were not true, and he hoped that his answer would get as wide a circulation. Mr. Bromley asked whether some of the inspectors who were put to watch these operations had not themselves been vivisectors, and were therefore in sympathy with them. Captain Hacking replied that that was a very unfair thing to say. The inspectors carried out their duties very creditably to themselves, to the House, and to the State. Mr. Bromley asked if there had not been such inspectors. The Speaker: The honourable member ought not to make such suggestions.

The Royal Army Medical Corps.

The Army Estimates, moved by the War Minister on March 7th, asked for a total sum of £41,465,000, which was £935,000 less than last year. Vote 3, relating to the Medical Service, showed an increase of £60,000. This was in part due to improvements in pay and conditions of service of army medical officers. For some years past the army medical service had not attracted sufficient numbers of young men. Complaints had been made by the medical profession, vigorously supported by the British Medical Association, of the inadequacy of pay, of the frequency of moves, and of the length of foreign service tours. Many of these complaints were well founded, and though steps were taken immediately it was some time before the new conditions could be put into force. The Cabinet appointed a committee to inquire into the pay and conditions of service in the medical branches of the three fighting services, as it was impossible to deal with one without the others. Following the report of the committee, the Royal Warrant of July, 1926, was issued, under which improved terms and conditions of service had been granted, and the British Medical Association was now recommending service in the Royal Army Medical Corps as a career for young qualified practitioners. More candidates were still wanted, and the Secretary of State wished to draw the attention of newly qualified medical men to two features of the new conditions. The time spent in a house appointment in a hospital would count as service in the army. The other innovation was that, after seven years' service, an officer could retire with a gratuity of £1,000. The army owed much to its medical officers, and he hoped that the reforms now operating would ensure a service as contented as it was efficient.

In the discussion which followed, Mr. Macpherson said that praise was due to the Secretary for War because he had considered the position of the Royal Army Medical Corps. He was delighted to hear that the British Medical Association was now recommending young men to join that service. Those who had followed the work of the service during the war knew how magnificent it was.

The motion to go into Committee was agreed to.

Major Glyn called attention to the fact that the working expenses of seven military hospitals, exclusive of salaries and maintenance, amounted to no less than £1,112,000. The Estimates Committee had recommended that there should be closer liaison between the services in hospital treatment. That had been carried out, and no doubt great economies had been effected, but £1,112,000 exclusive of salaries was too high a figure.

On the vote for men Dr. Vernon Davies urged that pensions should be more frequently awarded to men who were discharged from the army suffering from consumption. It was impossible for the Medical Board at Chelsea really to decide the question whether the disease was attributable to the conditions of service. No one could say when the tubercle bacillus might gain entrance into the human system. If a man had malaria, dysentery, or contracted a bad cold after exposure, or got pneumonia and then developed consumption, the Medical Board might hold his case to be attributable. And yet another man who had not had any of these diseases and was working at the same time might also develop consumption. The attitude of the War Office had caused dissatisfaction in the country. The War Office might take one of three courses. It might say that it was impossible to prove in any case that consumption was due to conditions of service. That might be harsh, but it would be logical. Secondly, the War Office might schedule a number of conditions or diseases which could be held to be producing causes of consumption. Thirdly—and this was the course which he would prefer—the War Office might institute a system of insurance under which every man in the service could be compulsorily insured against the possibility of contracting consumption. He urged upon the Secretary of State for War that this was a question that required consideration.

Dr. Fremantle congratulated the Secretary of State on the action he proposed towards the Royal Army Medical Corps. As a result of the recommendations of a committee which sat on this subject improvements had been made. Before the war the establishment of the Royal Army Medical Corps in officers was something like 1,000; since the war it was cut down to 900, and there were under 800 officers on the strength last year. This year only fifteen candidates had come forward to fill twenty-five vacancies, so that they were still in a backward position. The Secretary of State was appealing for short-service officers. When these men had become useful officers they would be entitled to return to civil life with a gratuity. The Army Council was carrying on with an elderly service increasing always in seniority. That made for great dissatisfaction among the officers. It was too early to judge the result of the new terms which had been offered. But young medical men would not take commissions in the fighting services unless those services took direct and vigorous measures to attract them. The Secretary of State had mentioned that day that there had been a reduction in the medical services of the Territorial Force in respect of casualty clearing stations. This was most serious. Great difficulty was caused in the late war because casualty clearing stations had to be improvised. The first shock of battle meant a large number of casualties, and if the clearing stations did not know their work great difficulties would arise. While the framework might be cut down, he hoped the Secretary of State would make arrangements whereby the personnel would continue to be trained to form a nucleus which would be available on the outbreak of war.

Sir L. Worthington-Evans, in reply, said that the point put by Dr. Vernon Davies was one of the most difficult medical questions that could be raised. Dr. Davies had said that it would be logical, though harsh, to refuse pension in all such cases, but it was better to be wrong in some cases than to take up such a position. It was not the fault of the administration that mistakes were made; it was due rather to the incomplete knowledge of the medical profession in regard to the causes of consumption. He assured Dr. Fremantle that the War Office was doing its best to follow the course that he had suggested. They intended to visit the medical schools in order to induce young medical men to enter the Army Medical Service.

Small-pox.

In a series of answers to Mr. Groves, Mr. Chamberlain said that in 1925 and 1926 "vaccination" or "vaccinia" appeared as the cause or one of the causes of death on the death certificates of nine persons, whose ages were respectively 5½ months, 8½ months, 3 months, 5 months, 5 months, 9 weeks, 17 days, 1 month, 6 months. A similar attribution of death was subsequently withdrawn from the certificates relating to four persons, aged respectively 4 months, 4 months, 7 weeks, 1 month. The latter certificates were withdrawn as the outcome of correspondence undertaken by the Registrar-General, but consisting solely of a routine inquiry asking the certifying practitioner whether he was of opinion that the cause of death was in any way associated with vaccination. It had been for many years the practice to question certifying practitioners about any indefinitely certified causes of death. In two of these reconsidered cases death occurred seven days after vaccination, in the third nine days, and in the fourth seventeen days. Mr. Groves also asked whether, in November, 1926, the medical officer for Moxborough, stating that a Mrs. Roberts, who had been confined six days previously, was suffering from small-pox, ordered her removal to hospital; that at her request the baby was taken to hospital with her, and was vaccinated two days later, and that it died at the age of 2 months. Mr. Chamberlain said he understood the facts were generally as Mr. Groves stated them. The death of the child was certified as due to (1) small-pox, (2) cellulitis of right leg.

Answering Mr. Wi[illegible], Mr. Chamberlain said the results obtained from the [illegible] vaccine lymph issued by the Governmen[illegible] had been uniformly successful. No case [illegible] of vaccinations with this lymph had been reported to the Ministry of Health in which a severe reaction had been attributed to the lymph. He had no control at present over proprietary lymphs, but regulations for standardizing all vaccine lymphs used in this country would come into force when the Therapeutic Substances Act, 1925, became operative.

Mr. Chamberlain added that during the thirteen weeks ended February 19th, 5,465 cases of small-pox were notified in England and Wales. He gave figures showing that in the Sunderland Poor Law Union in 1925, out of 5,326 births 379 died unvaccinated, 4,191 were successfully vaccinated, and statutory declarations of objection were made in respect of 577. Of 1,513 born in the Darlington Union in 1925, 78 died unvaccinated, 358 were successfully vaccinated, and there were 1,009 statutory declarations of objection.

Disinfection of Animals.—Mr. Guinness informed Dr. Fremantle that the test for disinfectants which the Ministry of Agriculture had adopted for use under the Diseases of Animals Acts was framed after full consideration and scientific advice, as being a test conducted under conditions which resembled as closely as possible the actual circumstances in which the disinfectants were used in practice. Dr. Fremantle asked if this had been agreed upon in consultation with other Government departments which were equally concerned in getting a reliable test. Mr. Guinness said that the requirements of the other offices were very different from those of agriculture. He did not think it necessary to have the matter reconsidered. In reply to a further question by Dr. Fremantle, Mr. Guinness said that he was not aware that brands of disinfectants approved by the Ministry were being freely sold to agriculturists in inferior strengths and not labelled in accordance with the Diseases of Animals Disinfection Order, 1926. Agriculturists and others required to use approved disinfectants by any Order issued under the Diseases of Animals Acts should be careful to see that the preparation they were obtaining for that purpose was labelled clearly as prescribed in the Disinfection Order of 1926.

The School Medical Service.—Lord Eustace Percy (President of the Board of Education) told Mr. Harris that a complete school medical service for children in public elementary schools should provide for medical inspection, for following up cases of defect found in the course of inspection, and for medical treatment of defects. Local authorities were required to provide for the inspection of all children on admission to school, on attaining the age of 8, and on attaining the age of 12 provision should also be made for the inspection of special cases and the re-examination of children previously inspected.

Ultra-violet Light.—On March 8th Sir *P. Cunliffe-Lister* (President of the Board of Trade) told Sir G. Berry that he understood the Miners' Welfare Committee had under consideration the question of establishing experimental installations for the production of ultra-violet rays in association with pithead baths provided under the Mining Industry Act, 1926. The matter was not free from difficulty.

Motor Lights.—Colonel Ashley (Minister of Transport), on March 8th, informed Brigadier-General Charteris that he was not aware of any motor headlight which provided an adequate driving light without some degree of dazzle. He was considering the question of seeking additional powers to deal with the lighting of road vehicles in a bill which he hoped to introduce.

Education of Fathers.—Mr. Chamberlain (Minister of Health) said, on March 8th, that his attention had been drawn to the "father-hood" class instituted by the authorities of St. Thomas's Hospital infant welfare centre. He was informed that the fathers did not attend lectures with the mothers, but came for informal talks with the medical officer. The procedure at St. Thomas's Hospital had obtained wide publicity, and he did not consider that there was any necessity for him to recommend the inauguration of these classes by other hospitals and by institutions under his control.

Pensions.—On February 1st the Ministry of Pensions had under its entire control twenty hospitals with 4,328 beds, and seventeen other hospitals with 2,158 beds were wholly reserved for pensioners. In sanatoriums and civil hospitals 8,152 beds were occupied by pensioners under treatment at the charge of the Ministry. The Ministry has not yet arranged to close any hospital during 1927-28. It was not yet possible to determine the ultimate requirements of the Ministry in hospital treatment. Claims made for pensions of all classes in 1926 numbered 21,750; of these about 14,500 were refused. The deaths of 19,550 pensioners were notified during the year.

Medical Inspection of Schools.—Answering Dr. V. Davies, Lord Eustace Percy said school medical officers of the Lancashire education authority were, when they examined children at a school, each accompanied by a nurse and a secretary. This arrangement appeared to be exceptional, and he was unaware of any special reason for its adoption in Lancashire. In that county the medical officer of health was also the senior school medical officer. The statement that the average cost throughout the county was £1 a head for each examination, as asserted by Colonel Woodcock, was wholly inaccurate.

Influenza.—In 105 great towns of England and Wales there were 249 deaths from influenza in the four weeks ended December 25th, 1926; 1,055 in the four weeks ended January 22nd, 1927; and 3,232 in the four weeks ended February 19th. During the last period the deaths from influenza in London numbered 754, in Birmingham 42, in Bristol 146, in West Ham 60, in Nottingham 91, in Leicester 46, and in Cardiff 52.

Prevention of Tropical Diseases.—Mr. W. Baker asked what sums were spent annually out of imperial funds or the funds of Crown Colonies, protectorates, or mandated territories for expert advice on medical subjects, excluding expenditure on regular medical services. Mr. Amery provided a table showing the following payments: Chief Medical Adviser to the Secretary for the Colonies, £1,500; expenses of Colonial Advisory and Sanitary Committee, £904; expended annually on advice of the Committee of the Tropical Diseases Research Fund, £2,400; Bureau of Hygiene and Tropical Diseases, £8,925; Imperial Bureau of Entomology, total revenue £8,100—proportion expended on medical objects unknown; British Social Hygiene Council, £1,000; hookworm eradication, Jamaica, £3,750.

Notes in Brief.

The Home Secretary is issuing to chief constables a memorandum reminding them of their powers to prevent the emission of smoke, steam, and sparks by steam tractors.

Since the issue of the draft regulations under the Lead Paint Act a conference with representatives of the industry has resulted in general agreement.

From the armistice to December, 1926, £50,270,000 has been paid in England and Wales in out-relief to able-bodied persons and their dependants.

The Minister of Health has no scientific evidence showing that bovine tuberculosis or other diseases are spread by the consumption of imported butter and cheese.

The report of the Committee on Juvenile Delinquency will be presented towards the end of this month.

Provisional notifications for diphtheria in England and Wales during 1926 were 51,067, and deaths 2,923. Provisional notifications for scarlet fever were 81,670, and deaths 667.

The Admiralty does not consider it necessary to appoint medical staffs to ships in reserve at the home ports, other than ships of the senior officers of the reserve.

Sir John Gilmour, answering a question about dental benefi[t] said approved societies were under no obligation to provide i[t]. The Scottish Board of Health had not negotiated a scale of charg[es] with the dentists. This had been agreed to by a Joint Dent[al] Committee, consisting of representatives of dentists and of th[e] interests of approved societies. He had no power to suspend th[e] scale.

The Minister of Agriculture has stated that 388 dogs were imported from abroad under licences issued by the Ministry durin[g] the six months ended February 28th last. One case of rabies wa[s] discovered among these animals, in a dog brought from India.

In the House of Lords the Diseases of Animals Bill passe[d] through Committee without discussion. On March 8th it was rea[d] a third time and sent to the Commons.

The Services.

DEATHS IN THE SERVICES.

SURGEON COMMANDER ALEXANDER GORDON ANDREWS, R.N. (ret.), died at Emsworth, Hants, on January 16th. He was the son of th[e] late Stephen Wilson Andrews of Bourne, Lincolnshire, and afte[r] taking the M.R.C.S. and L.R.C.P.Lond. in 1884, entered the nav[y] in the same year, and in the following year joined H.M.S. *Monarch* in the Channel Squadron. He was staff surgeon o[f] H.M.S. *Terrible* during the South African war and the Boxe[r] rising, and was present with the Naval Brigade at Tientsin. I[n] 1903 he became senior medical officer of the St. Vincent boys' training ship at Portsmouth, and in 1904 was appointed to th[e] charge of the Royal Naval Hospital at Yarmouth. On th[e] mobilization for war he joined the battleship *Prince George*, bu[t] in 1915 was appointed for special service at Chatham. He retire[d] in 1916.

Medical News.

ABOUT 150 members of the Inter-State Post-Graduate Assembly of North America, accompanied by Dr. Charles Mayo, will be in London on June 1st, 2nd, and 3rd for a post-graduate tour of northern Europe. While in London a programme of lectures will be arranged for them at Dartmouth House, the new building of the English-speaking Union. The following hospitals will arrange special programmes during the afternoons: St. Bartholomew's, Westminster, St. Thomas's, Middlesex, Charing Cross, the London Hospital, King's College Hospital, Prince of Wales's Hospital, Brompton Hospital for Consumption, the Infants Hospital, Vincent Square, the Cancer Hospital, the National Hospital for Diseases of the Heart, and the Chelsea Hospital for Women. Sir James Berry will give a reception for the members at the Royal Society of Medicine on the evening of Friday, June 3rd.

MR. ZACHARY COPE will lecture for the Fellowship of Medicine on common mistakes in the diagnosis and treatment of acute abscess on March 17th, at 5 p.m., at the Medical Society, 11, Chandos Street, W.1. On March 16th, at 4 p.m., Mr. Davenport will give a demonstration at the Central London Ophthalmic Hospital, Judd Street, and on March 18th Mr. Bourne will give a demonstration in gynaecology at the Samaritan Hospital, Marylebone Road. The lecture and both demonstrations are free to members of the medical profession. From March 14th to 25th the Chelsea Hospital for Women will hold a special course in gynaecology, and the Royal National Orthopaedic Hospital will hold a two weeks' course from March 21st. The London Temperance Hospital will commence a two weeks' course on March 21st primarily for general practitioners; from 4.30 to 6 p.m. there will be a lecture for half an hour and an hour's demonstration. The Queen's Hospital for Children starts a two weeks' course on March 28th, a special feature being demonstration of cases rather than lectures. From March 28th, for two weeks, the Royal Eye Hospital will give a series of afternoon demonstrations on the diagnosis and treatment of the eye. The Fellowship arranges for practical courses in anaesthetics and obstetrics and for clinical assistantships in gynaecology. Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A THREE months' course of lectures and demonstrations on clinical practice and hospital administration for candidates for the D.P.H. will be given at the North-Eastern Hospital, St. Ann's Road, Tottenham, N.15, by Dr. F. H. Thomson, medical superintendent, on Mondays and Wednesdays at 4.45 p.m., and alternate Saturdays at 11 a.m., commencing Monday, April 11th. The fee for the course, which complies with the requirements of the revised regulations of the General Medical Council, is £4 4s. Further particulars may be obtained from the Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C.4.

THE annual dinner of the Irish Medical Schools' and Graduates' Association will be held in the Abraham Lincoln Room, Savoy Hotel, on Thursday, March 17th, at 7.30 p.m., with the President, Sir W. I. de C. Wheeler, in the chair. The guest of the Association will be Vice-Admiral Sir Frederick Field, K.C.B., K.C.M.G.

WE have already mentioned on more than one occasion that on the evening of Monday, April 4th—the day before the reception in the Great Hall of the British Medical Association of the official delegates to the Lister centenary—Sir StClair Thomson will give an address at the social evening of the Royal Society of Medicine on "The Centenary of Lister—recollections by one of his house-surgeons." So much interest has already been shown in this announcement that the society has found it necessary to notify that Fellows, Associates, or members of the society, as well as others wishing to attend, must apply to the Secretary (1, Wimpole Street, London, W.1) for cards of admission.

A CONFERENCE of the Royal Microscopical Society will be held at Liverpool, from March 29th to 31st, under the presidency of Dr. James A. Murray, F.R.S. The subjects to be treated include: recent advances in medical microscopy, by Mr. J. E. Barnard; pneumokoniosis due to asbestos dust, by Dr. W. B. Cooke and Mr. C. F. Hill; experiments in stereo-photomicrography, by Dr. J. A. Murray; the diameter of the red cells of man before and after exercise, by Dr. Eric Ponder; and demonstration on surface tension, by Professor W. Ramsden. A discussion will be held on filterable viruses and the limits of microscopic visibility, and a popular lecture will be given by Professor J. Arthur Thomson on the microscopy of everyday life. Further information may be obtained from Mr. C. J. Lock, secretary of the society, 20, Hanover Square, W.1.

DR. W. ESSEX WYNTER will deliver an Emeritus lecture at the Middlesex Hospital Medical School on Friday, March 18th, at 3 p.m., on "The study of local diseases and remedies."

HOSPITALS situated within eleven miles of St. Paul's desiring to participate in the grants made by King Edward's Hospital Fund for London for the year 1927 must make application before March 31st to the honorary secretaries of the Fund, 7, Walbrook, E.C.4. Applications will also be considered from convalescent homes which are situated within the above area or which, being situated outside, take a large proportion of patients from London.

THE President of the Society of Public Analysts in his address to the annual general meeting commended the recent regulations as to preservatives in food. They placed both the public analyst and the manufacturer, he said, in a much happier position than before because they prevented an unreasonable analyst from extremes of unreasonableness, and confined each and every manufacturer within limits by going beyond which his competitors could not reap an unfair advantage without risk of punishment. He quoted statistics to show that the adulteration of food was steadily decreasing; this he attributed partly to the activity of the authorities, and partly to the efficiency of the public analysts. He urged manufacturers to avail themselves of the services of a chemist to maintain the purity of their products and to advise them in avoiding any contravention of the law. In his opinion the food of the country was never in a purer state than at the present time.

THE Institute of Industrial Welfare Workers is an association of men and women engaged in welfare work in industrial and commercial undertakings. It aims at obtaining a uniform standard of training and qualification for those undertaking such work, and also provides for the interchange of experience and information amongst its members. In the organ of the association, entitled *Welfare Work*, a series of articles is now appearing on industrial health and disease. To the current issue Dr. T. Pearse Williams contributes an article on rheumatism and allied disorders; and in April Sir Thomas Legge will write on industrial lead poisoning. Articles in previous issues have been contributed by Sir Thomas Oliver, Professor Collis, and other experts.

THE treatment at Bad Kissingen for the current year commenced on March 1st with the opening of the new Luitpold spring. The main season is considered to begin on May 1st. Details of the cure are published in our advertisement columns this week.

THE Cambridge University Press announces the preparation of a new series, the Cambridge Comparative Physiology, edited by Mr. J. Barcroft, F.R.S., Professor of Physiology at Cambridge, and Mr. J. T. Saunders, University Demonstrator of Animal Morphology. It will consist of a series of small volumes containing a comprehensive study of comparative physiology. The first three volumes, which will be ready this spring, will be: *The Comparative Physiology of the Heart*, by Dr. A. J. Clark, Professor of Pharmacology in the University of Edinburgh; *The Genetics of Sexuality in Animals*, by Dr. F. A. E. Crew, Director of the Animal Breeding Research Institute in the University of Edinburgh; and *The Comparative Physiology of Internal Secretion*, by Mr. L. T. Hogben, Assistant Professor of Zoology, McGill University.

MESSRS. ADAM HILGER, LTD., of 24, Rochester Place, Camden Road, N.W.1, who are manufacturers of scientific instruments for research, have published a bulletin of the development of their work during the twelve months ending June 30th, 1926, together with a list of recent references in scientific journals to instruments made by the firm.

THE issue of the *London Weekly* for March 5th contains an article recommending the provision of open-air schools wherever possible, and suggesting that so far as it can be arranged new schools should be built outside such towns as Leeds and Bradford where the tramway service provides easy access to country surroundings. This periodical is edited by Dr. L. Haden Guest, M.P., and other articles in the current issue deal with the disarmament problem, the Church of England in the Dominions, reform of the House of Lords, and Islam and the British Empire.

THE German Society of Urology has elected as honorary members Professors Alessandri of Rome, Fedoroff of Leningrad, Ferra of Turin, Young of Baltimore, Brenner of Linz, Völcher of Halle, and Wildbolz of Berne.

A MEETING of the British Institute of Philosophical Studies will be held at the Royal Society of Arts, 18, John Street, Adelphi, W.C.2, on Tuesday, March 15th, when Professor S. Alexander, M.A., will speak on naturalism and value. The chair will be taken by Professor A. Wolf, at 8.15 p.m. Applications for seats reserved for the general public should be addressed to Mr. Sydney E. Hooper, British Institute of Philosophical Studies, 88, Kingsway, W.C.2.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

IONIZATION IN CATARACT.

"G. T. B." will find in this issue a review of a book by Dr. Cantounet of Paris on the treatment of eye disorders by ionization. Cantounet did not find that it had any effect in cataract, but reports have been published by others which suggest that the method may be of some value when the lens changes are in their very *earliest* state, but all are agreed that when there are actual lens striae present the treatment has no effect. But as good results can be obtained in the same class of case by much simpler methods—for example, the use of a solution of sodium iodide with calcium chloride (of each 1 per cent.) instilled within the conjunctiva night and morning, and (where the patient is willing to put up with a certain amount of discomfort) the additional measure of injecting under the conjunctiva of 10 minims of a 1 in 6,000 solution of mercury cyanide to which has been added 3 minims of 1 per cent. acoin solution. The whole amount is injected deeply. The reaction promotes vascular flow in the ciliary region and so improves the health of the lens. Cataract is essentially due to failure of nutrition due to age changes in the ciliary vessels.

INCOME TAX.

Colonial Investments.

"S. A. E. L." left England in 1911 and practised in a colony until 1921, since when he has been living in the Riviera for reasons of health, visiting England for one or two months only each year. The income of himself and his wife is derived from investments in the colony. His health has now improved, and he intends to return temporarily to the United Kingdom and will probably do duty as a ship surgeon while his wife visits a distant colony.

*** In our opinion, as from the date of his return "S. A. E. L." will become resident, but not "ordinarily resident," in this country, and his maximum liability will be in respect of his (cash) earnings *plus* the amount of the colonial income which is remitted to him. He will, of course, be entitled to the usual personal allowance, *in our opinion, as a married man living with* his wife, and reduced rate relief. If, for example, his earnings are £300 and £300 is remitted to him, his liability for 1927–28 will be, assuming no change in the rate, etc., of the tax:

Earnings £300–£50 allowance...		£250
Income from abroad		300
		£550
Deduct personal allowance		225
		£325
Liability, £225 at 2s.	£22	10 0
£100 at 4s.	20	0 0
	£42	10 0

His liability for years prior to his return to England for something more than the mere temporary purposes of the past will not be affected.

Return of Expenses.

"ANXIOUS" has been asked by the authorities to state his expenses in detail and encloses a list (amounts not shown) for *comment.*

*** Some of the proportions seem rather high—for example, two-thirds for the electricity and gas accounts, whole cost of telephone, two-thirds insurances (presumably fire and burglary)—and "Anxious" will be fortunate if they are passed. The rent of the house should be based on the amount of the net assessment to income tax. The cost of the servant (food, etc., to be allowed for, as well as wages) should be divided roughly in the ratio in which her time is divided between domestic and practice work. The motor car insurance *should be separated from other* insurances. We presume that no dispenser is kept.

LETTERS, NOTES, ETC.

PAROXYSMAL PERIPHRASIA.

"N.3" sends us the following protest against what he terms the increasing spread of "paroxysmal periphrasia."

In the eighteenth century, he says, English people mostly used plain words when they had occasion to speak of bodily functions. These coarse expressions shocked polite Victorian ears, and indelicate facts like pregnancy or privies or bellyache came to be mentioned only by discreet circumlocutions. In course of time, as Charles Mercier once remarked, a nice word for a nasty thing would lose some of its niceness and drop out of fashion. Thus water-closet became w.c., and w.c. in turn became lavatory, scarcely recognizing itself as first cousin to the common soldier's latrine; and in refined America lavatory became toilet. All this verbal delicacy would rather surprise our rude great-grandfathers, who were not abashed to speak of a woman with child or to write "lying-in hospital" over a public building and dedicate it to their Queen. I sometimes wonder what they would think of a generation which allows vaginal syringes and suchlike wares to be flaunted in shop windows for all who pass to see . . . . . offended with the word urinal. An . . . . . grandmothers think of the "home . . . . . pages about sexual scandals, but draw the line at the word pregnant, replacing it with "in a certain condition?"

THE MACROPOLYCYTE.

DR. A. DEL CAMPO writes to us from the School of Hygiene and Public Health, *Johns Hopkins University, Baltimore, to say* that he has read with particular interest the paper by Dr. W. E. Cooke on the macropolycyte published in the first number of the JOURNAL for this year (p. 12). Dr. Cooke's results, Dr. del Campo says, confirm those stated in his article published in *Archivos de Cardiologia y Hematologia* (Madrid) in September, 1925. His researches, made in the laboratory of Professor Pittaluga in the School of Medcine, Madrid, afforded clinical confirmation of the observations as to the pleocaryocyte published by Pittaluga in the homage book presented to Ramon y Cajal in 1923. Dr. del Campo considers that the pleocaryocyte is a cell which occurs in *cachectic diseases,* as shown by his own observations in cancer and tuberculosis, in which diseases it is bigger than in pernicious anaemia.

STY TREATED BY ULTRA-VIOLET LIGHT.

DR. CHRISTINA BARROWMAN (Newcastle-on-Tyne) sends us two photographs to show the effect of treating the acute *stage of* a sty in the eye by application of compression doses with the air-cooled K.B.B. quartz lamp. The patient was a man, first seen on February 5th, when he presented, in addition to the sty, an oedematous area below it, and was *suffering considerable* pain. The applicator was applied for six seconds over the closed eye and for five seconds over the oedematous area. *The treatment* was repeated next day, and on the third *day the local* condition is shown by the photograph to have cleared away. The pain was immediately relieved after the first treatment, and this, Dr. Barrowman says, has been observed in the treatment of other inflammatory eye conditions, *but the dose must be correct.*

MIGRAINE.

DR. THOMAS LINDSAY (Tooting Bec Hospital, S.W.) writes: As an old victim of migraine I think the letter of Dr. Fraser-Harris (JOURNAL, *February 5th, p. 260) calls for some* comment. *In my* case the aura was a peculiar sensation on the tongue, *along with* all the classical visual symptoms. There was no headache for some time (one-half to three-quarters of an hour), and I was able to get home from school and into bed, then followed nausea and vomiting, and after that the terrible headache, *which* lasted about twelve hours. *I knew when I would have the headache,* but only after the aura had manifested itself, and *the periodicity* was most irregular, often months intervening between attacks. I had my second last *attack in my first year of* medicine at the age of 17, and my last attack at the age of 35. This last attack took me completely by surprise, but I knew at once what was going to happen, and got home from my *tennis club to bed* before the vomiting and subsequent headache. The sequence was exactly the same.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 50, 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified *in the* advertisement columns appears in the *Supplement* at page 67.

A British Medical Association Lecture

ON

IE POINTS IN THE SURGERY OF GASTRIC AND DUODENAL ULCERS.

LIVERED BEFORE THE LEICESTER AND RUTLAND DIVISION ON JANUARY 21ST, 1927,

BY

H. S. SOUTTAR, D.M., M.CH., F.R.C.S.,
SURGEON, LONDON HOSPITAL.

all the advances which have been made in surgery in the twenty years none are more remarkable than those the diagnosis and treatment of chronic ulcers of the nach and duodenum. Not only has surgery provided omplete cure for one of the most crippling conditions ch can affect a man in the full vigour of life, but geons have actually supplied physicians with a precise tem of diagnosis in a field which was formerly most cure. Routine explorations of the stomach and constant tact with the physical facts of its diseases have enabled geons to reveal its living pathology, and to build up a ical picture remarkable for its precision.

Before discussing the purely clinical aspects of the ject it will be well to note its extent, and to form a ar idea of the pathological entity we are discussing. extent can be fairly gauged by the admissions to a eral hospital. In the three years 1923-25 close upon 000 patients were admitted to the surgical wards of the ndon Hospital, and of these no fewer than 1,275 were mitted for gastric and duodenal ulcers. It would appear, refore, that over 4 per cent. of the cases admitted to surgical beds of a large general hospital are suffering m this condition. Remembering that the hospital missions form only a small fraction of the actual cases, will be seen that the disease is one of considerable quency, and must result in a large amount of ill health l incapacity. Moreover, the average individual who sults a surgeon for chronic gastric ulcer probably only s so after years of intermittent pain which has made almost intolerable. He is in the most active period of and many patients undoubtedly owe their trouble to strenuous lives they have led, and the irregular meals h these have involved. Perhaps this is an explanation he greater incidence in men. Of the 1,275 London pital cases above referred to 660 were gastric ulcers a male incidence of 70 per cent., and 615 were duo- l ulcers with a male incidence of no less than 86 per .—figures which agree closely with those found elsere by both English and American surgeons.

PATHOLOGY.

here is no more concrete pathological entity in surgery a chronic gastric ulcer, and its discovery at operation never be a matter of doubt. These ulcers occur most quently upon the lesser curvature near the pylorus, and the posterior wall. At the cardiac end of the stomach are rare, and on the greater curvature they are ctically never seen. Their actual cause is unknown, they probably commence as small acute lesions which dually develop into chronic ulcers. Indeed, there are e grounds for supposing that the extension of a chronic er is due to the formation of acute ulcers on its margin, this would account for the very marked periodicity ch is so characteristic of the symptoms of the disease. the early stages the mucous membrane alone is involved, the exposed submucous and muscular coats are rapidly acked by the gastric juices and a funnel-shaped ulcer produced which gradually penetrates the entire wall. ere the ulcer occurs on the lesser curvature the in- mmatory process extends into the lesser omentum, which omes thickened and distorted, a huge sheaf of lympha- s surrounding the coronary vessels. If the ulcer is on posterior wall it may become adherent to the pancreas the liver, and finally burrow deeply into its substance. posterior ulcer will often involve the transverse meso- on, and this is a matter of extreme practical importance since it exposes the middle colic artery to considerable risk of injury in the course of an operation.

It is characteristic of these ulcers that the tissues around should become densely infiltrated, and as contraction is thus interfered with the natural healing of the ulcer which might otherwise occur is prevented. Occasionally, however, healing does occur, and it may then be accompanied by gross constriction at the site of the ulcer, as is most strikingly seen in the hour-glass stomach produced by the contraction of a saddle ulcer. In a similar manner the healing of a pyloric ulcer may be accompanied by such contraction as to produce severe organic obstruction of the pylorus.

The pathology of duodenal ulcers is very similar to that of gastric ulcers, but they never reach such large dimensions and are never accompanied by the same degree of induration. They are most common on the posterior surface, and at the junction of the first and second parts of the duodenum. It is quite common to find two ulcers opposing one another, one on the anterior and one on the posterior wall; the latter, from its relationship to the gastro-duodenal artery, is liable to produce severe haemorrhage, whilst the former may readily perforate. When an ulcer on the anterior wall is healed its site may often be recognized as a thin, white, radiating scar, whilst in the active state the peritoneal surface becomes stippled with red points in a characteristic manner if it is gently rubbed with a swab.

The relation of gastric ulcer to cancer is still a matter of acute controversy, but it would seem that although carcinoma may develop on the basis of a chronic ulcer this is by no means a common event. The fact that in every chronic ulcer considerable displacements of the epithelium are liable to occur probably led to the idea that these displacements were malignant downgrowths. From the practical point of view, however, it is sometimes difficult to determine clinically whether an ulcer is or is not malignant, so that where there is any doubt its resection in a suitable case would always seem to be a wise precaution.

The actual causation of chronic gastric ulcers is quite unknown. In animals they are only produced with difficulty, and the most successful method has been that of feeding with food grossly contaminated with *B. coli*. On the one hand, it seems certain that infection plays some part in their production, but on the other it is obvious that, once the mucous membrane has been destroyed, the gastric juice can exert a very destructive action upon the exposed tissues. The fibrosis which naturally results prevents that contraction which is an essential process in the healing of any ulcer, and the continued action of the gastric juice is a constant irritant favouring its extension. The fact that gastric ulcers are so commonly associated with hyperchlorhydria, and that in duodenal ulcers this is almost invariable, suggests that the acidity of the gastric juice has an important bearing on the etiology of both conditions.

SYMPTOMS.

A chronic gastric ulcer usually presents a group of symptoms so characteristic that the diagnosis can be made upon the history alone. It occurs most often in men, and usually between the ages of 40 and 50, although no period of life is entirely free. The most characteristic feature of the symptoms is their periodicity, for they tend to come in attacks lasting, perhaps, for a few weeks, with longer intervals of complete freedom. The cause of this periodicity is unknown, for in general the ulcer does not heal between the attacks. It has been suggested that during attacks an extension of the ulcer is occurring, and in certain cases small acute ulcers have been noted on the margins of the chronic ulcer itself. As time goes on, however, and the ulcer becomes adherent to the surrounding structures, the interval of freedom becomes shorter, until finally the symptoms may become continuous.

The primary symptom is pain in the epigastrium, coming on at a definite interval after a meal. The interval may be anything from ten to ninety minutes, but it is usually constant for a given patient. The pain may be very severe, and it has the characteristics of a colic varying in intensity from moment to moment. It can be entirely relieved by emptying the stomach or by neutralizing its contents with alkali. The pain appears to be due either

to spasm or tension of the muscle wall of the stomach, the spasm of the muscle wall being in some way due to the presence of the ulcer. The acidity of the gastric contents would seem to play an important part in its production, since it is often most severe when the acidity is at its height and is immediately relieved by the ingestion of alkalis or other substances which neutralize the acid.

The pain is, however, seen in its most typical form in cases of duodenal ulcer, and here its mechanism is more easily understood. Here it comes on an hour and a half after food, when the acidity of the gastric contents is at its height, and it is evidently due to a violent spasm of the pylorus, which endeavours to protect the ulcerated surface of the duodenum from contact with the acid chyme. The relationship between the acidity and the pain is here clearly marked, for although small portions of the liquid stomach contents are being passed into the duodenum as a rule from an early stage, their degree of acidity is insufficient to excite the characteristic spasm.

As time goes on pain of an entirely different character may appear—a fixed burning pain in the back. This pain always indicates that the ulcer has penetrated the posterior wall of the stomach, and has eaten its way into the structures on the posterior abdominal wall, of which the pancreas is the one most often affected. It is apparently due to the direct irritation of nerve endings, and although it varies with the acidity it bears no relation to muscular spasm.

Vomiting is sometimes a prominent feature, and it may be welcomed by the patient for the sake of the relief which it brings; many of these patients, indeed, induce vomiting as the surest way of abolishing their pain. The vomiting may be intensely acid, and this is more likely to be the case if it occurs at a late period of digestion. It never has the persistent character by which it is marked in cases of carcinoma.

Haematemesis is seen in cases of gastric ulcer in two forms. In the one the bleeding occurs from small vessels of the mucosa, and although it may be severe it will always respond to treatment and is never fatal. The other form occurs at a late stage and is due to the erosion of a large artery by the ulcer. Its treatment forms as difficult a problem as any in surgery, and it is often fatal.

The story of a typical case of chronic gastric ulcer will thus be as follows. For many months the patient has suffered from attacks, which lasted for a few weeks, in which he has had epigastric pain, coming on an hour or so after meals, and relieved by vomiting. As time has gone by the attacks have become more severe and the interval of freedom shorter, till for some months he has not known what it was to be free from pain after meals. A constant boring pain in his back may have added to his troubles. He has been losing weight, and on one or two occasions he may have vomited blood.

The symptoms of a duodenal ulcer strongly resemble those of a gastric ulcer, but they present certain important differences. The pain appears at a later period—from one and a half to two hours after a meal. It often wakens the patient in the early hours of the morning when his stomach is actually empty of food, and it is often relieved by taking more food. This hunger pain, as it has been called, is the most characteristic feature of a duodenal ulcer. The periodicity of the attacks is very marked, and although it is not always the case the patient often presents a thin, drawn appearance, which is very characteristic. If haemorrhage occurs it is likely to be very severe, but as a rule blood is passed by the bowel and is not vomited. At the moment when the bleeding occurs the patient may become very pale and faint, but it may be only two days later that he passes the black tarry stool which indicates the presence of altered blood.

In cases both of gastric and duodenal ulceration we are unlikely to gain much information from a direct examination of the patient. Where the history is prolonged and the symptoms have been severe there may be marked loss of weight; where haemorrhage has occurred there may be definite anaemia, and sometimes the patient presents a marked pallor from a continuous loss of small quantities of blood, although no obvious haemorrhage has occurred. Examination of the abdomen may show a definite point of tenderness in the epigastrium, possibly accompanied slight rigidity, and where the latter chiefly affects the rig rectus it is suggestive of pyloric or duodenal ulceration.

Examination of the stomach contents by means of a t meal will enable us to discover the degree of acidity. The are two standard methods, those of Ewald and Rehf In the former the patient is given, on an empty stomac a slice of dry toast and a pint of weak tea, the contents the stomach being withdrawn at the end of an hour. the second, or fractional method, he first swallows a sm tube, and then takes a basin of thin gruel, samples bei withdrawn by means of the tube every fifteen minut The advantage of the second method is that the gradu rise of the acidity in the stomach contents can be note but it is doubtful whether the information obtained is more practical value than in the simpler method of Ewal Although the information obtained is not absolutely co clusive, it is certain that a high acidity of the gastr contents is almost unknown in carcinoma of the stomac and from this point of view it may be of diagnostic val in a doubtful case of suspected ulceration.

Radiographic examination has in recent years become increasing value, and in expert hands is capable of givi results of great reliability. The patient takes a meal co taining three ounces of barium sulphate suspended in sor thick medium so as to form a viscous emulsion. T shadow of the stomach contents is observed on a scree and the contents are displaced by the hands of the radi

FIG. I.—Small ulcer of lesser curve; interval of twenty minutes. Note persistence of niche and opposing indentation from spasm of muscle.

grapher so as to see if any of the opaque material remai behind in the crater of an ulcer. Should an ulcer present some of the barium emulsion will be caught in crater, and the persistence of this little fleck of barium the stomach is moved about is the characteristic featu (see Fig. 1). Opposite this small niche there is often a indentation due to spasm of the stomach wall at this poin and the combination of the niche with the indentation conclusive evidence of the presence of an ulcer. Rapi emptying of the stomach, distortion of its wall, and disto tion of the duodenal cap, are all suggestive of ulceration the stomach or of the duodenum, but their interpretatio must be left to the expert.

COMPLICATIONS.

The clinical picture of uncomplicated gastric ulceratio is thus exceedingly well defined, but it is liable to conside able modification if certain complications occur. Of thes the most important are:

1. Involvement of the surrounding organs, especially th liver and pancreas.
2. Pyloric obstruction.
3. Hour-glass contraction.
4. Carcinoma.

All these complications are accompanied by gross inte ference with the mechanism of the stomach, and it is striking fact that they are all associated with loss periodicity in the symptoms.

Take the first of these cases, where the ulcer penetrat into the liver or pancreas, or, more rarely, into th anterior abdominal wall. Not only will the patient hav no periods of relief, but the pain itself, though rendere worse by food, will never disappear. It acquires a burning

penetrative character, and in those cases where the pancreas is involved it characteristically radiates to the left shoulder. It is evident that such ulcers may open up large arteries, such as the splenic, or pancreatico-duodenal, and lead to immediately fatal haemorrhage.

Where the contraction of an ulcer has led to pyloric stenosis the periodicity of the symptoms will again disappear. The pain will become more constant, but will be due rather to the chronic gastritis which is present than to the ulceration, and it will therefore lose its acute

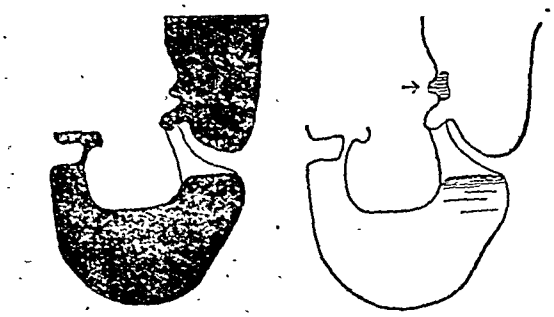

FIG. II.—Hour-glass stomach. Note small active ulcer, and level of fluid in distal sac.

character. The most striking feature, however, of pyloric stenosis is the vomiting of large amounts of food, possibly the contents of several meals. Often the stomach is enormously dilated, and active fermentation may add to the distension and discomfort of the patient.

Hour-glass contraction is almost limited to women, its production being probably conditioned by some degree of visceroptosis. It occurs most commonly in women of middle age, with a history, extending over ten years or more, of chronic dyspepsia. The pain is always severe, and vomiting may suggest obstruction. As there is, however, a marked degree of chronic gastritis the appetite will be less, and there is always gross loss of weight. The fragility of these women is often extreme. They have suffered years of misery as chronic dyspeptics, and one would imagine that their gastric mucosa could never recover its vitality. There are, however, no cases which may astonish the surgeon, and perhaps still more his medical colleague, with more brilliant recoveries. (See Figs. II and III.)

The relation of carcinoma to chronic ulcers is still a matter of dispute, but there can be little doubt that it is an uncommon occurrence. It should be suspected where the pain becomes more continuous, although usually less severe, where vomiting results in the evacuation of foul material with little relief, and where rapid loss of weight occurs. Gross loss of appetite and a positive distaste for food are common, but again the most striking feature is the loss of periodicity in the symptoms.

TREATMENT.

It was for a long time held that chronic ulcers of the stomach and duodenum would yield to medical treatment, and that complete healing of the ulcer would in time occur. Surgical explorations have, however, shown that this view can no longer be maintained. It is true that if the patient is placed in bed on a restricted diet all his symptoms will disappear, but if an abdominal exploration is undertaken it will often be found that the ulcer itself is still present, apparently entirely unaffected by the treatment which has been so successful in abolishing symptoms.

It would appear, indeed, that a chronic ulcer gives rise of itself to no symptoms at all, and it has been suggested that the periodic attacks which are so characteristic a feature of the disease are due to the formation of acute ulcers on its margin, probably as a septic process. However that may be, it is certain that a fully formed chronic ulcer can only be cured by surgical means, and it is on the face of it unreasonable to expect that a deeply excavated ulcer, fixed in indurated tissues, and bathed by active gastric juice, should be affected by any alterations in diet.

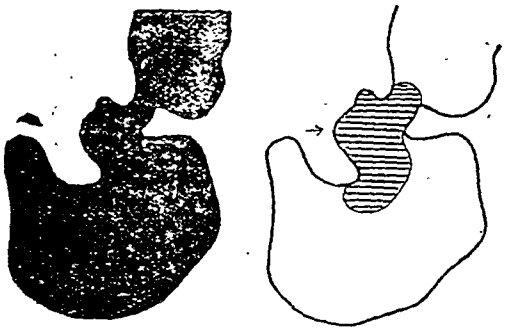

FIG. III.—Hour-glass stomach, complicated by extensive active ulceration involving pancreas and liver.

Of all surgical procedures for the treatment of these ulcers, gastro-enterostomy stands out as the first, and indeed there are few operations in any field of surgery which have met with such success. Introduced in Billroth's clinic forty-five years ago, and only modified in detail by succeeding surgeons, it can still claim absolute success in an overwhelming majority of properly selected cases.

The mechanism by which it acts is still a matter of doubt, but the most important change which it produces is neutralization of the gastric contents by the bile and pancreatic secretions which are thus brought into the stomach. When this neutralization is obtained gastro-enterostomy is completely successful in dealing with ulcers of the duodenum and of the pylorus, whilst it even succeeds in those ulcers of the lesser curve which lie in the neighbourhood of the pyloric antrum. It succeeds, in fact, wherever an opening can be made to the left of the ulcer, and only fails in those ulcers of the lesser curve which lie so far to the left that this condition cannot be complied with.

In a small percentage of cases, however, for causes which are quite obscure, neutralization is never completely effected, and the patient is then exposed to the possibility of a jejunal ulcer starting from the line of anastomosis. Moreover, gastro-enterostomy fails to give relief when the ulcer is so far towards the cardiac end of the lesser curve that it is impossible to place the opening to the left of it, whilst its success is uncertain in those cases where the ulcer has involved the liver or pancreas, and its application is often difficult in those cases where the contraction of a chronic ulcer has given rise to the gross deformity of hour-glass contraction.

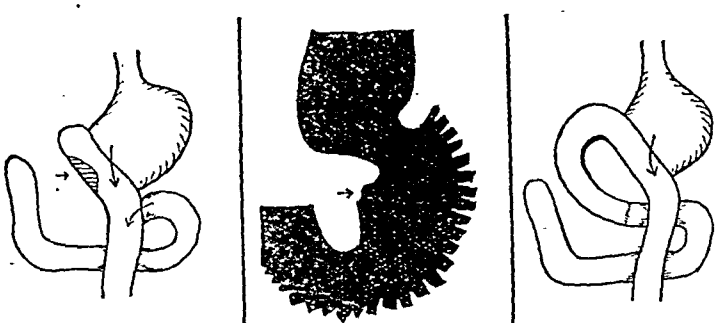

FIG. IV.—Huge jejunal ulcer, following Y gastrectomy. Cured by Polya's operation.

In the last two conditions, where the surrounding organs are involved or the stomach itself is grossly deformed, there is no question that the most satisfactory solution is partial gastrectomy. The method of Polya, as so largely developed by Moynihan and Sherren, has met with a success in these complex cases which rivals that of gastro-enterostomy for the simpler conditions. A Y anastomosis should not be performed, for the largest jejunal ulcer we have ever seen occurred after this operation. (See Fig. IV.)

The small ulcers occurring high up on the lesser curve still, however, present an unsettled problem. The patient can be cured, it is true, by partial gastrectomy, but the

FIG. V.—Schoumaker gastrectomy. Result after six months.

large section of stomach sacrificed seems scarcely justifiable. In the ingenious method of Schoumaker the portion of stomach excised can be greatly reduced, and the operation is so performed that a stomach is left which is almost normal in appearance and function. (See Fig. V.) The operation, however, is technically difficult, and an equally good result is more easily obtained if the stump of the

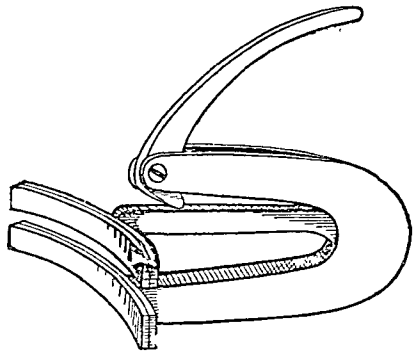

FIG. VI.—Gastrectomy clamp.

stomach is anastomosed to the jejunum, as in Polya's operation.

To facilitate this procedure I have devised a clamp based on that of Schoumaker, but of simpler construction. (Fig. VI.) It consists of two members joined to one another, which can be forced together with great power by a toggle lever. On the front of each member is a

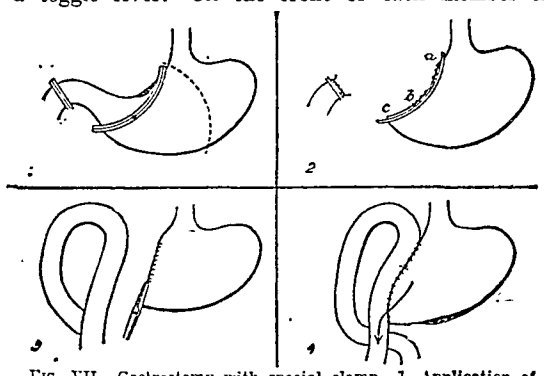

FIG. VII.—Gastrectomy with special clamp. 1, Application of clamp. 2, Stomach excised, front members of clamps removed, crushed edges sutured. 3, Clamp removed, Lembert sutures inserted, forceps applied to stoma. 4, Operation completed. New lesser curve protected by jejunal loop, which is itself protected from angulation.

detachable face. After crushing the stomach, amputating, and removing these faces, a fringe of crushed tissue projects which can be sutured with great facility, and in almost perfect asepsis. The clamp is used as follows.

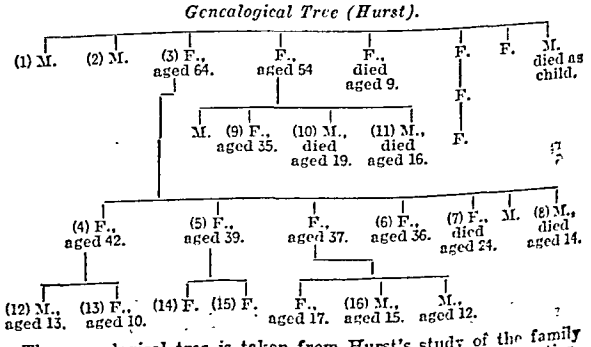
After dividing the duodenum and freeing the stomach the clamp is so applied as to allow of the removal of the ulcer with a minimum of stomach. The rejected tissue is now cut away, and the fringe of tissue in the clamp is touched with pure carbolic. The front plates of the clamp are removed, the upper two-thirds of the crushed tissue edge is sutured, and the lower third is caught in forceps. The clamp is removed and the suture line is invaginated. A loop of the jejunum is now brought up to the stomach and attached all along the suture line, whilst an anastomotic opening is formed in the usual way between the jejunum and the portion of the stomach stump held in the forceps. (See Fig. VII.)

The operation has the advantages that it is very tidy and clean, that very little stomach need be removed, that the alignment of the jejunum along the suture line prevents this from leakage, and protects the jejunum from kinking, and that the outlet from the stomach is reduced to dimensions approaching the normal. On the other hand, the dotted line shows how the same method can be applied to the most extensive gastrectomy for carcinoma. The operation is followed by a convalescence remarkable for its smoothness, and so far the after-results have been unexceptionable.

HEREDITARY FAMILIAL CONGENITAL HAEMORRHAGIC NEPHRITIS.

BY

A. CECIL ALPORT, M.D.ED., M.R.C.P.LOND.,



MEDICAL UNIT, ST. MARY'S HOSPITAL, PADDINGTON.

THE question of heredity as an etiological factor in nephritis has been studied and reported upon from time to time. Fortunately the condition is rare, and the literature shows only half a dozen families affected in this way. As far back as 1875 Dickinson[1] published a family tree showing eleven cases of albuminuria in a total of sixteen persons in three generations Attlee,[2] Guthrie,[3] and later Hurst,[4] Pel,[5] and Kidd,[6] and Eason, Malcolm Smith, and Buchanan[7] have also described the disease and noted its familial and hereditary tendency.

The cases which have come to my notice belong to a later generation of the series studied by Leonard Guthrie and Hurst, and it is with this family I propose to deal. Guthrie designated the condition "idiopathic or congenital hereditary family haematuria," and used the word "haematuria" rather than nephritis. He gave as his reasons for this that it is "persistent for many years, but may vary in extent; liable to paroxysmal exacerbations with influenzal-like symptoms; not marked by oedema, ascites, or cardio-vascular disturbances; not due to uric acid or oxalates, and is not accompanied by urine of low specific gravity."

The part of the same family described by Hurst showed definite nephritis with low specific gravity of urine and the presence of albumin, some blood, and granular and hyaline casts; the blood pressure was increased, and towards the end anaemia, cardio-vascular changes, and oedema were marked features; these cases terminated in death from uraemia. Hurst thus named the condition "hereditary familial congenital haemorrhagic nephritis," and this terminology is accurate for most of the affected members of the later generations of the family.

Genealogical Tree (Hurst).

The genealogical tree is taken from Hurst's study of the family records, with the addition of the children of the third generation, born since his original communication appeared.

On January 4th, 1924, I was asked to see a boy belonging to the third generation of this family—No. 16 in Hurst's genealogical tree and the second child of the third daughter of No. 3. This boy's great-grandmother, not shown on the genealogical tree, lived to the age of 90 years and was extremely deaf. Her daughter (No. 3) had a severe attack of haematuria after the birth of her first child, and similar, but less severe, attacks after the births of her younger children and also after eating black currants and drinking claret. She is very deaf, but her general health is excellent. Her two elder brothers, both suffered from haematuria and died in childhood. One sister is deaf and another slightly so, but they do not suffer from disease of the kidneys.

All her children, with the exception of one male child, developed haematuria. In three cases (Nos. 5, 6, and 7) the condition followed the consumption of black currants. In one case (No. 8) black currants did not affect the patient, but strawberries, asparagus, and catching cold or influenza brought on attacks. A female child (No. 7) was deaf, and died in her twenty-fifth year; a male (No. 8), who died at the age of 14, was also very deaf. Another female (No. 6) is not dead as stated in Hurst's genealogical tree. She is alive and quite well except for her attacks of haematuria, but is stone deaf. Case No. 4 is slightly deaf. Two nephews (Nos. 10 and 11), deceased, suffered from nephritis and deafness. Her third daughter, unnumbered, the mother of my patient, denies having had haematemesis as stated in Eason, Malcolm Smith, and Buchanan's article, but suffers from backache and attacks of blood and albumin in the urine. She has only had one "bad attack," when she passed "pure blood." Her eldest child, a daughter, is quite free from the disease, and her younger son has shown no definite signs. The second child, a boy (No. 16), has nephritis and some nerve deafness. His case is fully described below. Her eldest sister (No. 4) has two children; both of these (Nos. 12 and 13) are well grown and in good health, but suffer from the complaint. Their cases are also described below. The children (Nos. 14 and 15) of her second sister (No. 5) are not affected.

It will be seen from this that nearly all the children of three generations of one family suffer from haematuria or nephritis associated with deafness. The deafness, which has not been stressed in the literature on the subject, is one of the most distressing features of this extraordinary disease.

Mr. J. Gay French has kindly supplied me with the following information on the deafness of two of the cases belonging to the first generation of the family, as shown in Hurst's genealogical tree. In 1916 he examined both of these patients and found them to be suffering from nerve deafness; the hearing in one of them has become slightly worse since then.

This nerve deafness is apparently the type of defective hearing to which members of this family are subject. It occurs not only in the individuals who have nephritis or haematuria, but also in those who are otherwise perfectly healthy.

When I first saw Case No. 16, in 1924, he was 14 years of age, tall for his age, intelligent, and keen on sport of all kinds. The apex beat was well within the mid-clavicular line, the heart sounds were normal, and there were no bruits. The vessels were not thickened, systolic blood pressure 118 mm. Hg, diastolic 55 mm. Hg. The urine, specific gravity 1015, was acid with a fair amount of albumin and some blood. Microscopically numerous red blood corpuscles, a few granular casts, and a large number of uric acid crystals were seen. The culture of a catheter specimen of urine was negative. Urea concentration test (Maclean) 2.5 per cent. of urea. Blood count: red blood corpuscles 5,120,000, haemoglobin 80 per cent., colour index 0.88—a slight secondary anaemia. Leucocytes were diminished in number. Differential count: polymorphonuclears 27.5 per cent., small lymphocytes 59 per cent., large lymphocytes 9 per cent., hyalines 2.5 per cent., eosinophils 1.5 per cent., and transitionals 0.5 per cent. The patient also suffered from nerve deafness to a considerable degree in both ears. The treatment was to reduce the food proteins and to give sufficient potassium citrate to render the urine neutral in reaction and allay the possible kidney irritation, due to the presence of uric acid crystals.

In May, 1924, the general vascular and urinary conditions showed no appreciable change. The blood urea was 12 mg. per 100 c.cm., albumin 0.075 per cent. Because of the definite family history of attacks of haematuria occurring after eating black currants, strawberries, and asparagus, I tested his skin reaction to various protein groups with a view to desensitizing him, should he prove sensitive to any given protein. The results were comparatively disappointing. He showed a ++ reaction to fish, fowl, and leaf vegetables—cabbage, lettuce, etc.—but the elimination of these from his diet and treatment with medicinal peptone, 1 grain one hour before breakfast, daily for a month, failed to diminish the albumin and blood in his urine to any extent.

In July, 1924, he developed furuncles in the external meatus of each ear and on one cheek. They cleared up after a course of *injections of an autogenous staphylococcal vaccine*. The urine still contained albumin 0.05 per cent. and blood corpuscles microscopically. He played football throughout the following winter, and in April, 1925, showed considerable improvement—heart normal; systolic blood pressure 108 mm. Hg, diastolic 65 mm. Hg; blood urea 27 mg. per 100 c.cm.

In September, 1925, he had an attack of influenza, and this was followed by a large increase of blood and albumin in the urine. The coagulation time of his blood was found to be five minutes—showing a delay. Treatment with calcium lactate 15 grains twice a day for three months had little or no effect upon the coagulation time or upon the urinary condition. Although I was anxious not to interfere unduly with the general routine of his life at school, I refused to allow him to play football last winter, because of the possibility of an onset of uraemia following a chill.

On April 7th, 1926, I saw him again and tried the effect of intravenous injections of 1 grain of calcium chloride, followed by further injections on April 14th and 21th. After each of these the urine showed decided improvement, there being considerably less albumin and blood in it and no casts. The coagulation time of the blood was reduced to three and three-quarter minutes. Further attempts to find a cause for the condition have proved unavailing. The Wassermann reaction and the complement fixation test for tubercle are both negative. An examination of the pharynx and nose by Mr. Cecil Graham proved negative; the tonsils had been removed some years ago and there were no adenoids. On transillumination of the right antrum of Highmore, however, a dark shadow was found below the right eye and light was less appreciated by the patient in that eye than in the left. An exploratory operation, the washing out of the antrum with sterile water and the culture of this fluid, failed to yield an organism of any kind. An *x*-ray photograph taken a week after the operation shows the right antrum still very opaque; there is no apparent explanation of this.

A further effort to find some focus of infection resulted in the cultivation of a non-haemolytic streptococcus (*S. viridans*) from the stools.

Buchanan, in his investigation of the blood and urine of two of Eason's cases, found pure growths of non-haemolytic streptococci. These were biochemically identical with those obtained from the teeth, tonsils, and tonsillar regions of the patients. Buchanan states that "a feature of note in primary cultures was the delay and feeble nature of the growth, which only appeared between the third and sixth days of incubation." He also produces experimental evidence of the production of symptoms of acute nephritis in rabbits as the result of intravenous injections of non-haemolytic streptococci (*S. faccalis*) obtained from two cases of subacute nephritis. Albumin in considerable quantity appeared in the urine within the first week of inoculation. In some cases it increased daily in amount and persisted until the animals died, in others it gradually decreased and almost disappeared. Microscopically the urine of these animals showed hyaline, granular, epithelial, and blood casts and blood epithelial cells were very numerous. In some animals which succumbed shortly after inoculation an accumulation of fluid in the pericardial sac and abdominal cavity was a marked feature, and the kidneys presented the typical microscopical changes associated with acute diffuse nephritis.

In view of these observations I injected into the veins of two rabbits a large dose of a first subculture of the non-haemolytic streptococcus (*S. viridans*) obtained from the stools of my patient by Dr. Fleming of the Pathological Institute of St. Mary's Hospital. The results were negative; the rabbits showed no symptoms of any kind, the temperature remained normal, and an examination of the urine ten days and a fortnight after the injections showed no signs of albumin, blood, or casts. The animals were still perfectly fit a month later. Another culture made recently from the stools of this case showed an abnormal number of *S. faccalis* and a few colonies of haemolytic streptococci.

Towards the end of last summer two cousins of this patient were brought to me. They were over on holiday from California, where they had been advised to live because they are suffering from the family disease.

The boy (No. 12), according to the mother's statement, developed haematuria when he was 2 years old. On examination he was found to be well grown; his systolic blood pressure was 122 mm. Hg, and the diastolic 78 mm. Hg, with slight thickening of the arteries. The heart was not enlarged and there were no bruits. The urine contained 0.23 per cent. of albumin and a trace of blood. Microscopically it showed an occasional blood and epithelial cell, but

no casts. The blood urea was 26 mg. per 100 c.cm., and the urea concentration was 1.95 per cent. Cultures from faeces yielded colonies of *S. viridans* only: 1 c.cm. of a first subculture of the living organism was injected into the veins of a rabbit; the urine collected and tested three weeks later was normal. Microscopical examination of the kidneys showed nothing pathological.

The girl (No. 13) had a history of haematuria, commencing three weeks after birth. Her systolic blood pressure was 118 mm. Hg, diastolic 75 mm. Hg. The heart was not enlarged, there were no bruits, and the arteries were normal. There was only a trace of albumin in the urine, which was faintly positive to chemical tests for blood. Microscopically a few red corpuscles, some uric acid crystals, and one hyaline cast were seen. The blood urea was 17 mg. per 100 c.cm.; urea concentration test 2.1 per cent. Culture from faeces yielded numerous *S. viridans*, and a few colonies of a haemolytic streptococcus appeared on the plate; 1 c.cm. of a living subculture of the above was injected into the veins of a rabbit and the urine collected and examined three weeks later. It showed a faint trace of albumin on boiling, and microscopically a few red corpuscles, numerous pus cells, but no definite casts. Culture of a fresh specimen of the urine failed to produce any streptococcal colonies. The rabbit was then killed by chloroform, and the kidneys examined by Dr. Newcombe, who reported as follows: "Glomeruli rather swollen and some of them contain a small amount of albuminous exudate. No sign of leucocytic infiltration. Tubules show some early fatty degeneration."

The small dose of streptococci given, and the shortness of time intervening between the injections and the microscopical examinations, may account for the relatively slight changes found in the kidneys.

Other cases of nephritis occurring in a family may be of interest.

At the beginning of May, 1924, two brothers, Charles J., aged 17, and Harry J., aged 14, were admitted to the Medical Unit wards of St. Mary's Hospital suffering from general oedema, blood and albumin in the urine, and an increase of blood pressure. They had been delivering milk early one morning; both got wet through and cold, both developed symptoms of nephritis, and they were admitted on the same day. There was no evidence of any infection immediately preceding the onset in either case. They both had scarlet fever five years before admission, and the elder brother had had measles, diphtheria, and chicken-pox as well. There was no history of oedema or albuminuria following these attacks.

The mother states that her father, an uncle, and her grandmother died of cancer, while her grandfather, two uncles, and an aunt died of consumption. There was, however, no family history of kidney disease. The elder boy proved to be a case of acute nephritis. On admission his renal efficiency was impaired —blood urea 0.056 per cent.; urea concentration test 1.6 per cent. After treatment the blood urea fell to 0.041 per cent.; urea concentration test 2.75 per cent. of urea. He has been discharged, and has been in the best of health ever since.

The condition of the younger boy on admission was more severe. He had considerable oedema, with albumin, blood, and casts in the urine. The apex beat was in the mid-clavicular line, but there was no bruit. The systolic blood pressure was 160, diastolic 100. The fundi were normal. Blood urea 0.146 per cent., urea concentration 1.7 per cent. The picture was one of chronic parenchymatous nephritis with considerable interstitial changes, progressing towards small white kidney. He was discharged relieved some weeks later.

On readmission in October, 1924, his condition had deteriorated considerably. Oedema, drowsiness, headache, and nausea were marked features. The breath smelt urinous. The apex beat was 1½ inches to the left of the mid-clavicular line, extra-systoles were present, but no bruits. The urine was scanty, and contained 0.8 per cent. albumin, granular and hyaline casts, but no blood. Urea concentration 1.35 per cent., blood urea 0.240 per cent. In the end he developed pericarditis and died on February 16th, 1925. *Post mortem* small white kidney was found.

COMMENTS.

1. Hereditary familial or congenital nephritis is a definite entity, and the kidneys in these patients are more susceptible to damage by the toxin of an unknown organism than is the case in the normal person.

2. The organism probably belongs to the streptococcal group.

3. In the first case investigated (No. 16) the coagulation time of the blood was delayed; intravenous injections of 1 grain of calcium chloride reduced the coagulation time and caused a reduction in the amount of blood and albumin in the urine. Calcium lactate given by the mouth is useless, as it is not absorbed by the intestines.

4. Cultures of *Streptococcus viridans* found in the stools of this patient, and of his cousin (No. 12), failed to produce the disease when introduced into the veins of a rabbit. Cultures of the stools of another case (No. 13), which showed both *S. viridans* and haemolytic streptococci, caused changes in the urine and kidneys of a rabbit after intravenous injections.

5. Deafness is a marked feature in nearly all these cases.

6. The male members of a family tend to develop nephritis and deafness and do not as a rule survive. The females have deafness and haematuria and live to old age.

7. The last couple of cases are interesting evidence of the variations in the course of nephritis. The kidneys of two members of the same family were attacked, apparently by the same organism, at the same time, and under exactly the same conditions. The elder brother contracted acute nephritis, which cleared up completely, the younger developed parenchymatous nephritis, passing into small white kidney, and ending in death.

I am indebted to Professor Langmead of the Medical Unit, St. Mary's Hospital, for leave to publish the notes on the last two cases.

THE SCHICK TEST:

ITS APPLICATION IN AN INSTITUTION FOR MENTAL DEFECTIVES.

BY

ROBERT MUNRO, M.B., CH.B.ABERD.,

ASSISTANT MEDICAL SUPERINTENDENT, ROYAL EASTERN COUNTIES INSTITUTION, COLCHESTER.

THE intradermal reaction in guinea-pigs was first used by Romer in 1907 for carrying out virulence tests in diphtheria. His technique was supplemented in 1913 by Schick, who introduced a test known by his name. It is possible by means of this test to determine whether or not an individual is susceptible to an attack of diphtheria. I have carried it out by injecting into the substance of the skin 0.2 c.cm. of standardized diphtheria toxin into the left arm. The most favourable site is the flexor aspect. The best results are obtained by using an "Agla" all-glass syringe (Burroughs Wellcome) fitted with a No. 214 rustless needle. The needle is inserted intracutaneously for a distance of an eighth of an inch. If the injection has been accurately effected considerable force is necessary to move the plunger onwards. After the injection has been done a wheal about half an inch in diameter is visible which is caused by the pitting of the hair follicles. A corresponding dose of heated toxin is injected into the opposite forearm. A separate syringe is used for this control dose.

Four types of reaction may be observed, and in 90 per cent. of cases in healthy subjects the results may be read after twenty-four hours, though after thirty-six to forty-eight hours the reactions are clearer.

1. *Negative.*—After twenty-four hours both arms show no local reaction except a puncture where the needle was inserted. There may be slight transient redness due to trauma. This coloration fades in the course of twelve to twenty-four hours.

2. *Positive.*—At the end of twenty-four hours there is seen at the site of the injection a circumscribed area of redness which varies from a quarter of an inch to one inch in diameter. It attains its maximum intensity by the fourth day, and thereafter gradually fades, leaving a brownish pigmentation. Persons who show this reaction are susceptible to diphtheria if exposed to infection.

3. *Negative and Pseudo-reaction.*—There is a red flush with a dark centre; the characteristic is that the area of redness is equal or approximately equal on both forearms. The patient who shows this reaction is immune to diphtheria if exposed to infection. It is due to some unknown constituent in the toxin broth.

4. *Positive and Pseudo-reaction.*—In this case a pseudo-reaction is observed in addition to the positive reaction. A red flush appears on both arms. The flush, which is much larger on the test arm than on the control, lasts for a longer time. The reading of this arm is best seen on the fourth to sixth day. The reaction is rather rare.

The patient is immune if the reaction is negative or pseudo-negative, but is susceptible if the reaction is positive or pseudo-positive. It is advisable to examine the sites of the injection daily for five days, and it is very important that careful "readings" should be done, especially on the second and fourth days.

It is advisable to use the diluted toxin for the tests as soon as it is received from the laboratory, as otherwise it is liable to lose its potency, and should a dozen successive healthy adults give a negative result, provided the test has been carefully and properly applied, the conclusion should be that the toxin may not be absolutely reliable. The undiluted toxin is less expensive than the diluted; and it remains sterile and reliable for several weeks, provided reasonable care is taken in storing it.

Individuals who prove susceptible to diphtheria, as determined by the Schick test, may be rendered immune by the injection of toxin-antitoxin. The injection of diphtheria prophylactic causes immunity to develop a few weeks later, and this immunity may probably last during life. Diphtheria prophylactic consists of diphtheria toxin and diphtheria antitoxin prepared according to the standard adopted by the American Government. Babies up to 6 months old seem to be immune, and do not need immunization. The large majority of children between the ages of 6 months and 5 years give a positive reaction, and therefore it is possible to dispense with the Schick test between these ages. All these children may safely be injected with the toxin-antitoxin mixture without any preliminary testing. Between these ages it would seem advisable, as a routine measure, to immunize all children against diphtheria. It will be found that if children between the ages of 6 months and 5 years are tested the percentage of positive reactions will be about 60 to 70. Above the age of 5 years only those patients who exhibit a positive Schick reaction should receive the injections.

Active artificial antidiphtheria immunization is carried out by the injection of toxin-antitoxin mixture. It is usual to give three doses of 1 c.cm. subcutaneously at intervals of seven days. It may be considered preferable to begin with a smaller dose—for example, 0.2 c.cm.—and to follow it up with 0.4 c.cm., 0.8 c.cm., and 1.5 c.cm. at intervals of five to seven days. This is advisable in the case of those who give a positive and pseudo-reaction. The toxin-antitoxin mixture remains quite potent for several months if kept in a cool place.

The injections of toxin-antitoxin are attended by a certain amount of danger, and several unfortunate incidents have occurred. In an institution near Vienna forty children recently received prophylactic injections against diphtheria, and six died with symptoms of general diphtheria intoxication. Several of the others exhibited skin necroses of varying degrees. The fatalities were possibly due to a dissociation of the toxin-antitoxin mixture. As a result of several unfortunate occurrences an important modification has been described by Glennie in which the toxin is rendered non-toxic by the agency of formaldehyde. The resulting toxoid-antitoxin mixture acts as a very quick, reliable, and safe immunizing agent, and is generally free from unpleasant effects. Ramon has employed formalized toxin for conferring immunity on Schick-positive cases. He gives three injections, with an interval of three weeks between the first and second injections, and two weeks between the second and third injections. The doses employed are 0.5 c.cm., 1 c.cm., and 1.5 c.cm. He claims that by this method he is able to render 98 per cent. of his subjects immune in eight weeks. Certain observers have prepared a mixture of antitoxin and anatoxin. The resulting preparation has been called "ananti." It is a protein-free vaccine against diphtheria, and the time required to secure immunity would appear to be about the same as that taken by toxin-antitoxin. It does not seem advisable to attempt to confer immunity by toxin-antitoxin injections on patients who suffer from advanced heart and kidney affections, or in those recovering from acute infectious diseases.

Many adults after receiving the first dose of 1 c.cm. of toxin-antitoxin do not suffer from any local or general disturbance, except perhaps slight lassitude, and soreness of the arm at the site of the injection. In many cases it is advisable to give a commencing dose of 0.5 c.cm., and follow up with two doses of 1 c.cm. at seven-day intervals. Patients who suffer from asthma, migraine, and debility should receive a small initial dose of 0.05 c.cm., and then 0.5 c.cm., followed by two doses of 1 c.cm. The frequency of local and general reactions increases with age. Severe reactions are rare before the age of 8 years.

The Schick test and antidiphtheria immunization were resorted to at the Royal Eastern Counties Institution, Colchester, because repeated small outbreaks of diphtheria had occurred during the last few years; twenty cases in fifteen apparently separate outbreaks occurred during 1924, and seventeen patients were attacked in the early part of 1925.

The test was commenced in 1925, and was applied only to patients whose relations or friends gave consent. The total number of patients tested was 1,037. The results were as follows:

Age.	Number Tested.	Positive.	Percentage of Positive Reactions.
Under 5 years	7	3	42.8
5 to under 10 years ...	48	16	33.0
10 to under 15 years ...	157	42	26.7
Over 15 years	825	187	22.6
Total	1037	248	23.9

The number of patients tested below the age of 5 years is too small to be of any practical value. It has been noted that between the ages of 2 and 5 there is a distinct loss of immunity, which increases again in children of school age. The latter increase is possibly due to these children acquiring from their neighbours slight infections, not sufficient to cause disease, but nevertheless allowing them to acquire the necessary antitoxin to combat infection. Interesting observations have been made which show that children who prove to be susceptible to diphtheria on admission to hospitals may gradually develop resistance to the disease. The longer the residence of these patients in hospitals the more likely is this immunity to result. It would appear that in diphtheria, to which our susceptibility is not very high, a spontaneous process of immunization can eventually occur by the inhalation of small and subinfective doses of bacteria.

It will readily be understood that in certain cases it is rather difficult to apply the Schick test accurately to mental defectives. Great care must also be exercised during the administration of the toxin-antitoxin mixture.

The number of members of the staff tested was forty-seven, and eighteen of these gave a positive reaction. This percentage (38 per cent.) is high, but may to a large extent be accounted for by the fact that the members of the staff who were subjected to the test, and encouraged to have it done, were those who were readily liable to sore throats, tonsillitis, and general minor maladies. The usual proportion of positive cases over the age of 20 with the Schick test is from 15 to 20 per cent.

I injected the 248 patients who gave positive reactions with toxin-antitoxin mixture obtained from Messrs. Burroughs Wellcome and Co., London. Calcium lactate was administered before and after the injections. The patients were then kept in bed for eighteen to twenty-four hours, the temperature taken, and the general condition carefully noted. Only one reaction occurred, and it was transient. It consisted of pyrexia, headache, and slight local reaction resulting from the injection of 1 c.cm. of toxin-antitoxin mixture; eighteen members of the staff also received the "injections." Unfortunately two mild reactions occurred which necessitated their confinement to bed for a few days. The initial dose employed was 0.5 c.cm., followed by two doses of 1 c.cm. The interval between the injections was seven days.

No case of diphtheria has occurred in the institution since the test was commenced and artificial antidiphtheria immunization carried out. I hope later to test the Schick-positive cases again, and, if necessary, to re-inoculate.

This may readily be effected from three to six months after the injections. It is claimed that after three injections with toxin-antitoxin 70 to 90 per cent. of those treated are found to be immune after eight weeks.

Interesting figures have been published showing that in America of 90,000 Schick-tested, immunized, and treated school children, 14 got diphtheria, while of a similar number not tested or treated 56 acquired the disease. An extensive campaign has recently been started in New York to popularize antidiphtheria immunization. It would seem advisable to apply the system whenever a careful study of the epidemiological situation convinces us that it may be resorted to with advantage.

Another application of the Schick test is in the clinical diagnosis of diphtheria. A true case of faucial diphtheria will give a positive Schick reaction, but a carrier of virulent diphtheria bacilli will give a negative reaction. One observer recently noted twelve cases of diphtheria in children with a negative Schick reaction, but in the majority of the patients the disease proved to be nasal diphtheria. The test is of the greatest value in school epidemics. Children can be tested, and within twenty-four hours may be divided into two groups—the immune and the susceptible.

One of the chief difficulties in the use of the Schick test is the pseudo-reaction, which is due to the presence in the toxic filtrates of some substance which is more stable than the specific one, and which causes rise of temperature and other reactions. It is important that the toxin-antitoxin mixture should not be used after exposure to a temperature below 0° C.

The most favourable age for the administration of diphtheria prophylactic is from 1 to 5 years.

I am much indebted to Dr. F. Douglas Turner, medical superintendent of the Royal Eastern Counties Institution, Colchester, for allowing me to publish this article and for his valuable advice regarding the work. My thanks are due also to Dr. R. A. O'Brien, director of the Wellcome Research Laboratories, for giving me suggestions in the necessary technique.

THE MORTALITY OF ACUTE APPENDICITIS.

BY

JOHN B. HUNTER, M.Ch., F.R.C.S.,

SURGEON, ROYAL NORTHERN HOSPITAL; LATE SURGICAL REGISTRAR, UNIVERSITY COLLEGE HOSPITAL.

I PUBLISH the following figures in the belief that they indicate that the safest plan to adopt in treating acute appendicitis is to operate at once irrespective of the duration of the disease and of the local conditions obtaining.

All authorities are agreed that there is a steady increase in the incidence of appendicitis.

Deaths from Appendicitis in England and Wales (Registrar-General).

	Male.	Female.	Total.
1915	1441	1062	2503
1916	1474	1129	2603
1917	1390	1053	2443
1918	1298	1118	2516
1919	1278	1151	2429
1920	1389	1142	2531
1921	1474	1237	2711
1922	1524	1211	2735
1923	1608	1218	2826
1924	1545	1211	2756
1925	1624	1238	2862

These figures show an increase in mortality, but do not indicate the percentage mortality of the disease.

Adams[1] recently brought forward figures that had been collected from St. Thomas's Hospital, together with others already published by Love[2] from the London Hospital. They showed that the percentage rate of mortality in appendicitis is by no means as low as the general impression would indicate. In both these hospitals two methods are adopted in the treatment of the disease—one in which immediate operation is undertaken, and the other where delay is advocated if the patient is in the third to sixth day of the disease. The patient is watched, and if the condition is progressive, operation is undertaken.

The percentage case mortality is weighted by the cases of general peritonitis; Adams remarks that, if we omit these cases, "the St. Thomas's mortality comes down to 2.7 per cent. and that of the London to 3.5. These are very respectable figures, and seem to me to justify the gospel of immediate surgical treatment."

Further improvement in these figures can only be obtained by the early recognition of the disease, and especially is this the case in children, in whom the interval between the disease being limited to the appendix region and general peritonitis is frequently short. The advantage of delay in operation seems very doubtful; all its advocates appear to be agreed that it can only be followed under hospital conditions. This teaching must have its repercussion first on the general practitioner and later on the general public, and does not appear to me to be safe.

When an analysis of the cases treated on delayed lines is made it appears that at the London Hospital 109 cases out of a total of 341 were "unsuccessfully delayed," and at St. Thomas's Hospital 71 out of 214—in each case approximately one in three. It seems probable that the cases "unsuccessfully delayed" must be in a worse condition to withstand operative intervention than if they had been operated on when first diagnosed; the mortality in these cases is in fact higher than that of cases of local abscess which underwent immediate operation—at the London Hospital 6.4 per cent. compared with 4.6 per cent., and at St. Thomas's Hospital 14 per cent. compared with 4.2 per cent.

The figures at University College Hospital are taken for five years—from 1921 to 1925. The practice at this hospital has been to treat all cases diagnosed appendicitis by an emergency operation, irrespective of the day of the disease or the presence or absence of an abscess. Further, all cases diagnosed appendicitis are admitted to the surgical side, and are therefore under "one man control"—a point of considerable importance, as Adams has pointed out.

We therefore get in these figures the result on the case mortality of one quite definite line of treatment—namely, immediate operation. The cases have been divided into those that were drained and those cases in which the abdominal wall was sutured and no drainage employed. This gives a rough idea of the character of the disease, allowing for slight variations in the treatment of different operators; those cases that were drained either had general peritonitis or considerable collections of localized pus. The total number of cases was 602; of these, 274 were closed and 328 drained; 21 died (3.5 per cent.).

The number of cases of general peritonitis amongst these was 62, or about one-tenth, and the case mortality was 11—a percentage of 17.7. The mortality in the remaining 540 cases was 10 (1.8 per cent.). Two died of obstruction other than paralytic ileus, five with localized abscess, one of abscess of the lung, one from pneumonia, and one from spreading cellulitis of the abdominal wall. Among the cases dealt with, 95 were children under the age of 14; the mortality in these cases was 6—a percentage of 6.3 as compared with the above average of 3.5; of these 6 cases 5 died of general peritonitis. These figures bear out the seriousness of the disease in children, and the necessity of early diagnosis and immediate operation.

This fact is further brought out in the Registrar-General's figures for appendicitis and typhlitis for 1925, in which the deaths are arranged according to ages.

Years.	Males.	Females.	Total.
0–15	415	341	756
15–25	307	180	487
25–45	351	263	614
45–65	383	323	706
65–75	126	96	222
75 and over	42	35	77

It is stated by most authorities that the third to the sixth day is the dangerous stage at which to operate. It would appear probable that this statement rests on false premisses. Where immediate operation has not been advocated the cases are treated medically, and a number of

these successfully respond to this treatment. But the others, owing to extension of the disease, require surgical intervention, as is shown above, in approximately one in three of this type of case; and these being the worst cases, the mortality is higher, and gives the impression that this period is a peculiarly dangerous one. It does not appear to be so if immediate operation is undertaken.

Although it is a little difficult accurately to determine the day of the disease, I have done so as far as possible with these 21 fatal cases, and give for comparison the figures for all cases. The duration of the disease at the time of operation is shown in the following table.

Duration of Disease.	Deaths.	All Cases.
24 hours	2	175
48 ,, ...	7	142
3 days	1	91
4 ,, ...	2	57
5 days and over	6	137
Unknown	3	3

Of the six fatal cases shown of five days and over, one was wrongly diagnosed salpingitis and operation was delayed, and one was admitted and treated medically for ten days.

If we take the case mortality up to three days, we see that it is 9 in 315, and from three days up to five days and over it is 9 in 285; further, four of these deaths occurred in patients over the seventh day of the disease. This does not appear to be an undue preponderance in the case fatality between the third and sixth day.

If the relative figures of cases drained or sutured are taken as an index, the severity of the disease certainly appears to increase with the duration.

Table showing that the Number of Cases drained increases with the duration of the Disease.

Duration of Disease.	Closed.	Drained.
24 hours	125	48
48 ,, ...	60	82
3 days	33	58
4 ,, ...	20	36
5 days and over	35	101
Unknown	—	3

The presence of pus, however, is the indication for drainage, and we should expect to find it on the third day and over rather than in the earlier period. These figures, then, represent a pathological process rather than the severity of the disease, as it is well known that numbers of cases with abscess formation recover without surgical intervention.

In discussing the influence of immediate operative treatment on the mortality of appendicitis any other factor that is likely to influence that mortality should be taken into account, and in my opinion the method of approach is of considerable importance.

In the greater number of the cases quoted above the muscle-splitting incision was employed. The advantage of this appears to be that the diseased area is directly exposed, frequently the whole operation is conducted in a small compartment completely shut off from the general peritoneal cavity, and the natural extension of the disease, if pus be present, can be followed into the pelvis, very often without grossly soiling the rest of the peritoneum. Naturally this point is not of great importance if general peritonitis is already present, but in a number of cases this fact cannot be accurately determined before the abdomen is opened. I therefore think that McBurney's incision plays an important part in the successful treatment of acute appendicitis.

The figures I have given, showing 1.8 per cent. case mortality, excluding the general peritonitis cases, and 3.5 per cent. for all cases, appear to me to be further evidence in favour of immediate operation in acute appendicitis.

I am indebted to the surgeons at University College Hospital for permission to use these statistics.

ANAPHYLAXIS AND ULTRA-VIOLET LIGHT TREATMENT.

BY

ALEXANDER BRYCE, M.D., C.M.GLASG.,

BIRMINGHAM.

ANAPHYLAXIS has been defined as hypersensitiveness to foreign proteins—either direct protein extracts or the products of various micro-organisms not necessarily pathogenic, and not in themselves toxic. The alarming symptoms and depression are said to be explained by the formation of an antibody, probably a very insoluble precipitate in the blood serum of the patient, profoundly interfering, like histamine, with the capillary circulation and producing an asphyxia in the tissues themselves.

The following diseases have been attributed to its operation: asthma, bronchitis, hay fever, certain skin affections, angioneurotic oedema, cyclic vomiting, periodic diarrhoea, and the migraine-epilepsy syndrome.

Many specific methods have been used in the treatment of these disorders, but the only one common to the whole group is the use of peptone in small gradually increasing doses, never large enough to produce any pronounced reaction. The resultant immunizing action is said to be due to the detachment from the cells of antibodies which destroy the antigen in the blood. Auld, on the other hand, regards the antigen-antibody product as the cause of the anaphylactic shock. What is perhaps of more significance than either suggestion is the fact that leucocytosis is certainly produced by the reaction to peptone and other definite chemical substances, the bone marrow being stimulated to produce with great rapidity at least a double quantity of leucocytes. Though we have no very clear picture of the way in which the curative results are brought about, yet as similar results accrue from the use of ultra-violet rays in many of the maladies mentioned, and as we have some knowledge of the method whereby they do their work, it occurred to me that consideration of the facts might in some degree illumine the subject. It must be premised that by no means all cases of asthma or allied maladies are due to protein sensitization. Some may be due to nervous reflexes, some to hereditary diathesis, whilst others may require the combination of all three factors. I propose, therefore, to give the results of ultra-violet therapy in a typical case of spasmodic asthma and bronchitis of the most severe character, in a typical case of protein sensitization, and in a typical case of asthma alternating with eczema.

Miss B., aged 45, had been subject to the most violent attacks of asthma for over twenty years, each attack confining her to bed for many days and sometimes weeks, where she would lie with cyanosed countenance, struggling for breath, wheezing râles with slight expectoration being heard two or three rooms away. Sometimes slight relief was obtained by pitrenalin, sometimes by adrenaline, and sometimes by morphine, but her life was a burden, and the last few attacks looked as if they might be fatal. Early in 1924 I commenced irradiation of the back and chest with the quartz mercury vapour lamp on the one and the carbon arc lamp on the other, alternating after a few minutes. From the first treatment she began to experience relief, although it was many months ere the wheezing quite disappeared. For the succeeding year a weekly treatment has enabled her to live without any discomfort or even suggestion of asthma and bronchitis.

Miss E. S. for many years had sudden violent attacks of a suffocative feeling in the throat, with a sensation as if pepper had been sprinkled over it, followed by intense wheezing inspiratory and expiratory efforts, mucous râles, and a sense of impending death. Many kinds of treatment were tried by laryngologists and physicians, including pollantine and peptone; finally adrenaline in three-drop doses subcutaneously produced relief in three minutes or less, although it left the patient in a most exhausted condition. Skin testing elicited the fact that acid fruits, and especially raw apples, appeared to engender these attacks, and care in dieting reduced the attacks considerably but not completely. For close upon twenty months this patient has been acting as my assistant in the treatment of cases by ultra-violet light rays, besides which she has had many direct irradiations over the chest and back. For over a year she has been quite free from attacks despite occasional dietetic trespass.

Miss N. L., aged 23, has been an asthmatic from birth. The asthmatic attacks were suddenly replaced by universalized eczema, for which many kinds of treatment, both external and internal, were tried for a year without success. She then consented to try ultra-violet light, with the result that six treatments in three weeks completely cured the eczema, and she is persevering with the irradiations in the hope of completely eradicating the asthma.

I have seen many cases of neuritis and lumbago cured by the use of ultra-violet light. I believe such cases are due to a specific anaphylaxis excited by proteins absorbed from the bowel while it is in a state of catarrhal inflammation. The sudden incidence is probably due to exercise creating a local acidosis from the lactic acid produced in the muscles, which tends to make the cells more sensitive to the proteins.

At least one of the three cases I have cited was a pure example of anaphylaxis, and, in her, peptone failed completely, whilst ultra-violet irradiation was a complete success, as it was in the other cases. Now it has been demonstrated that exposure to the sun's rays causes a general hyperleucocytosis with a relative neutropenia and a strong relative lymphocytosis. I frankly admit that this is comparable with the leucocytosis produced by the injection of peptone, and it is quite possible that this helps to account for the anti-anaphylactic action of ultra-violet light rays. But it is only one of the remedial results of ultra-violet light, and probably the least effective; this doubtless accounts for the frequent failure of peptone, and in any case for the short period of protection it affords. Another valuable therapeutic effect of ultra-violet rays is their directly germicidal action on the body, increasing the bactericidal powers of the blood, thus reducing the formation of bacterial toxins.

Probably the most useful function of ultra-violet rays is their power to increase the absorption of calcium and phosphorus, which, with the formation of vitamin D from the cholesterol in the skin, is doubtless the main factor in the cure of rickets. This also leads not only to the better nutrition of the bones and nervous system, but also to the alleviation of spasm and the induction of a calmative effect on the nervous system. Nor must it be forgotten that there is an increase of iron in the blood and a decided rise of haemoglobin in the erythrocytes, diminishing the risk of dyspnoea and asphyxia, so potent a factor in asthmatic conditions.

Finally, the internal secretions of the thyroid and adrenal glands are increased, and they are both valuable in the treatment of asthma and allied conditions.

It will be observed that the ultra-violet light treatment of asthma counters the varied factors in its causation, and is valuable, not only for cure, but also for prophylaxis.

A METHOD OF ESTIMATING CARDIAC OUTPUT.

BY

I. HARRIS, M.D.,

PHYSICIAN, LIVERPOOL HEART HOSPITAL.

THE problem of the correct treatment of heart disease reduces itself largely to cardiac output. The common type of heart failure means diminished cardiac output, and we shall never be able to tackle the problem of heart failure properly unless we have a reliable method for determining the output of the heart.

The following is a description of a method for estimating cardiac output. The underlying principle is simple. The venous pressure is measured by inserting a needle, preferably in the cephalic vein of the arm. A given number of heart beats are admitted. Then the pressure is taken again, and from the increased venous pressure we calculate the output per beat, or, if desired, per minute. It will be seen that the principle underlying this method is the determination of the single output by variation of the venous pressure. Particulars are as follows.

The pneumatic tourniquet of a sphygmomanometer is placed on the arm; a needle with as wide a bore as possible is inserted in the cephalic vein and connected with a manometer containing a solution of 0.7 per cent. sodium chloride and 0.5 per cent. citric acid. The venous pressure is now taken. Then the artery is compressed very rapidly by means of the airbag so as to obliterate completely the brachial artery. The venous pressure is taken again, after which the arterial blood is allowed to enter the limb for the space of 5, 10, or 15 beats by relaxing the airbag. At the same time the pressure must remain high enough to prevent the venous circulation from being re-established.

A record of the number of beats which were allowed to pass into the lower part of the upper extremity. It will be seen from this chart that one is able to recognize those beats which do not completely pass through and to account for them in calculation.

The pressure in the veins is now taken again. It will be seen that it is necessary to take the venous pressure three times: first, when the circulation in the veins as well as in the arteries is free; secondly, when the circulation is cut off in the veins as well as in the arteries; thirdly, after a known number of beats have been admitted, the venous circulation still being cut off. The first and the third measurements are essential for our purpose, the second serving as control only.

The following readings are typical:

Venous Pressure Experiment.

V.P.=4 inches.
After compression=9 inches
After eight beats (see chart)=23 inches.

$$\therefore \frac{\text{Rise}=14 \text{ inches.}}{=1.75 \text{ inches per beat rise.}}$$

Case of specific carditis. Wassermann reaction ++; blood pressure 145/105; pulse rate at time of experiment=120 per minute.

It remains to say a word in regard to the counting of the beats, which is not so simple as might be imagined. The only satisfactory method of getting a reliable count is to place the pad of a Mackenzie's polygraph on the radial artery and record the beat by means of the needle on a photographic slide, such as is available in the electrocardiograph.

I am indebted to Dr. Crawford, assistant physician, Liverpool Heart Hospital, for valuable assistance in carrying out the experiment.

THE PROGNOSIS IN FRACTURES OF THE OS CALCIS.

BY

P. MALPAS, M.B., CH.B., F.R.C.S.,

SURGICAL REGISTRAR, ROYAL INFIRMARY, LIVERPOOL.

IN any case of fracture two questions must be answered: How long will the patient be incapacitated for work and require compensation? and To what extent will he be permanently crippled?

The investigation here reported was undertaken to determine the duration of the disability, and the degree of final impairment of function in cases of fracture of the os calcis. Twenty-five such cases were treated at the Northern Hospital, Liverpool, in the period 1921 to 1924. Of these, only fourteen reported for re-examination after completion of treatment; they were all men, and their average age was 45 years. In every case the fracture was caused by a direct fall on the heel.

For comparative purposes the period of disability was taken as the time between the date of the accident and of the man's resumption of a permanent occupation; in most cases this was determined by proceedings under the Workmen's Compensation Act. The average was eleven months. In seven cases the period was between eight months and a year; the shortest period was three months, and the longest twenty months.

The final results were difficult to assess. All the patients were ultimately able to resume moderately heavy work. None became industrial cripples. All complained of pain in the heel when running, or walking fast on uneven surfaces, such as cobble-stones, or in damp weather. In

one patient these symptoms had persisted for seven years after the fracture.

To elucidate the factors determining the disability, I compared the clinical and radiological appearances in those patients who did well and returned to work within six months, with those of the patients in whom the disability persisted for more than twelve months. Certain factors seem to have no bearing on the prognosis; all cases showed varying degrees of callus excess below the malleoli; a slight valgoid deformity was present in two cases only. The presence of a plantar spur was common, but in one case only did it seem to cause part of the pain and require the use of an excavated heel, which partially relieved symptoms.

Comparison, however, of the range of movements of the foot and the radiological appearances led to certain definite conclusions.

In the group of cases with a short period of disability the movements of inversion and eversion of the foot were, with one exception, grossly limited, but free from pain. Radiological examination showed extensive comminution of the os calcis and osseous ankylosis of the astragalo-calcaneal joints. In the one exception the joint surfaces were intact, and only the lower part of the bone had suffered compression.

In the second group, of inveterate cases, the movements of the foot had a freer range, but were attended with pain on full eversion. The radiological appearances showed relatively slight amount of bony damage. In one case, indeed, the lamellar structure of the bone was completely restored five months after the accident, though with no corresponding clinical improvement. A constant feature of all the inveterate cases was the irregularity of the articular surfaces for the astragalus. In no case was bony ankylosis present.

The radiological findings and the pain on movement point to the condition of the subastragaloid joints as being the determining factor in prognosis. At these joints occurs the second half of the movement from full inversion to full eversion of the foot, a movement elicited only by exertion, and effected by a vertical rotation of leg and astragalus on the os calcis. An osseous ankylosis of these joints produces a permanent but painless limitation of this movement, a loss which is by no means crippling; one man, indeed, returned to his work as a window cleaner in four months. On the other hand, a traumatic arthritis of these joints is perpetuated by any movements requiring eversion of the foot. As is always the case, fibrous ankylosis is more painful than osseous.

Conclusions.

From this confessedly small series the following conclusions arise:

The average period of disability after fractures of the os calcis is eleven months. The length of the period depends on the condition of the subastragaloid joints, and not directly on the amount of bone damage.

When these joints are ankylosed as a result of the fracture the foot improves in six months to an optimum stationary condition, with a limited but painless range of eversion of the foot.

Should the joints escape entirely the prognosis is so much the better, but when an incomplete fibrous ankylosis results from the fracture, improvement is slow and eversion is often permanently attended by pain.

The principle attributing most of the residual disabilities of fractures to implication of neighbouring joints is well exemplified by this series of cases.

My thanks are due to Mr. McMurray, honorary orthopaedic surgeon of the Northern Hospital, for his help, and permission to examine many of his cases, and to Dr. Oram for the use of the radiograms.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A FATAL CASE OF ACUTE PULMONARY OEDEMA.

A NUMBER of cases of acute pulmonary oedema, most of which have fortunately responded to the recognized treatment, have recently been reported. The following fatal case seems worthy of note.

A factory girl, aged 16, was brought to the East London Hospital for Children in the early morning of January 14th, 1926, in a collapsed and breathless condition. She had done an ordinary day's work, had been out for a walk after supper, and went to bed at 11 p.m. perfectly well. At midnight her sister, who was sleeping in the same room, was awakened by her vomiting and gasping for breath. She was hurried to the hospital, and I saw her immediately on her arrival.

She was a well-nourished girl; she was very restless, rolling from side to side, and clutching at her throat. She was cyanosed, and her expression very anxious. Frothy, straw-coloured fluid was streaming from her mouth and nose. The heart was somewhat enlarged, and a systolic and presystolic murmur was heard at the apex; the heart rhythm was regular, and the pulse 80. The bases of the lungs were full of bubbling râles. The liver was not enlarged, and the spleen not palpable. There was no oedema of the ankles. A hypodermic injection of atropine 1/100 grain and morphine 1/4 grain allayed her restlessness, but she complained of intense thirst, although frothy fluid was streaming from her mouth. Two hours after the onset of her symptoms she died.

I ascertained from her mother that three years previously she had been in an infirmary for "heart trouble," but had led a normal and healthy life since then without any symptoms at all.

At the *post-mortem* examination, conducted the next day by Dr. Temple Gray, pathologist to the hospital, the heart was found to be enlarged and fatty, and there was definite mitral stenosis. The lungs were sodden, and large quantities of fluid exuded from them. Frothy fluid was also found in the bronchi.

The point worthy of particular note is that the rhythm of the heart was regular throughout the attack. The question arises as to what was the cause of the sudden onset of the alarming and fatal symptoms.

I am obliged to the resident medical officer, Dr. A. G. Ogilvie, for permission to publish this case.

M. M. POSEL, M.R.C.S., L.R.C.P.,
Resident Casualty Officer, East London Hospital for Children, Shadwell, E.

EXTENSIVE NECROSIS IN CHICKEN-POX.

THE following case of necrosis complicating varicella presents some unusual features which make it worthy of record.

On December 24th last I saw a female child, aged 2 years and 9 months, who had contracted chicken-pox from her sister, aged 8. The temperature was 103°, the pulse 132, and the tongue was coated, but the throat was normal. She objected to being moved. There was a slightly reddened, tender patch over the lower part of the right shoulder-blade alongside a vesicle. There were not more than twenty vesicles in all on the body and head. The heart and respiratory sounds were normal. Ichthyol ointment (20 per cent.) was applied on lint covering a wide area; the bowels were moved, and antipyrin prescribed in small doses every four hours. The following day the temperature had fallen a degree, but the general condition had not improved. The area of redness over the right shoulder-blade had increased and there was a wide margin of tenderness beyond.

During the succeeding forty-eight hours the condition grew worse. *The affected area became discoloured and the patient more* toxic. No further vesicles appeared. The temperature varied from 100.5° to 102°. The child was very fretful, restless, and rambling in her talk, and slept badly. On the fourth day she did not appear to see distinctly. She was, however, taking Benger's food and fluids in abundance. On this day I asked Dr. A. Whyte Cassie to see her in consultation. A small necrosed patch, rather smaller than a shilling, was then present at the original site of the inflammation, and below this the skin was discoloured. Tenderness and muscular spasm extended to the vertebral column posteriorly and to the middle line of the chest and abdomen anteriorly. There was tympanites and constipation. Dr. Cassie advised that the treatment should be continued, and small doses of brandy given.

The necrosed patch increased in size daily. There was no suppuration, but the body became dusky and mottled. Wet boric dressings, changed twice daily, were applied. By the morning of December 30th the patch, *roughly oval in outline, measured about* 1½ by 3 inches. On December 31st I asked Dr. Seiller, the medical officer of health of the district, to see her. The necrosed patch was then double the size of the preceding day and was beginning to separate at its upper margin. He advised continuance of the boric soaks, but felt, with me, that the prognosis was very bad. As a last resort I injected 7½ c.cm. of antistreptococcal serum about 10 p.m., but the child died between 2 and 3 a.m. on January 1st.

The points of interest manifest in the case are: (1) The virulent, though not widespread, infection conveyed to the patient by her sister, a mild case seen sixteen days previously, who was never a day in bed. (2) The house and children were spotlessly clean; necrosis complicating

chicken-pox is generally associated with uncleanliness. (3) Only one vesicle showed necrotic change. (4) The child's health previously had been good.

S. NORMAN DYKES, M.B., Ch.B.Glasg.

Ibrox, Glasgow.

ESTIMATION OF THE CURE OF BILHARZIASIS.

THE decision whether a patient has been cured of bilharziasis depends mainly upon the microscopical examination of the urine. The last few drops that are passed are the most likely to contain the ova, and the best plan is to let the patient express the last portion of urine into a test tube, so that it can be centrifugalized and examined without delay.

When a child is experiencing slight cardiac depression during the third and fourth week of the emetine treatment, as evidenced by a quickened pulse and fretfulness, the ova may disappear temporarily from the urine. Absence of ova during treatment may also be caused by local reaction from unskilful injections or from any general indisposition, so that it cannot be depended upon as evidence of cure; this can be judged as certain only when frequent examination of the urine shows a complete absence of ova, either alive or degenerated, and only an occasional leucocyte. If treatment has been unsuccessful, careful examination of the urine will reveal live ova within a month or six weeks. By that time the antimony or emetine will have been excreted, and the comparatively small parasitic worms will have recovered from the effects of the drug.

A fresh infection may cause a strong eosinophilia, but it will not cause ova in the urine for at least three or four months. A large proportion of patients with bilharziasis are indigent school children, Indians, and natives whose constitution is undermined by irregular and insufficient feeding; special attention must be paid to the earliest signs of cardiac depression. A warning is needed against the oral treatment of patients who cannot be kept under constant medical supervision. Children are not readily persuaded to continue treatment after their obvious symptoms have disappeared; under the emetine treatment this disinclination may indicate early cardiac depression, which may demand a temporary suspension of treatment.[1]

In a boy, aged 4 years, 6 grains (0.36 gram) of emetine hydrochloride, given intramuscularly over a period of forty-nine days in doses ranging from one-sixth to one-third of a grain, appeared to have been successful, the patient showing general improvement in health and no toxic effect from the drug; but numerous living ova, with a slight recurrence of haematuria five weeks later, made it necessary to give a further course of 6 grains in twenty-nine days, in doses of from one-third to two-thirds of a grain. Toxic effects were seen only during the last few days of treatment, when there was slight drowsiness and vomiting after the two injections of two-thirds of a grain of emetine. Six weeks later living ova were again present in the urine, rendering a further course of treatment necessary.

The use of emetine periodide[2] has shown that it compares favourably with intramuscular injections of emetine hydrochloride; but it has yet to be proved that the results are permanent, or how far oral treatment may not be of limited service in view of the cost of the drug and the difficulty of supervising patients with bilharziasis. The emetine treatment becomes effective only when slight toxic effects begin to appear as a result of the accumulation of the drug during the third and fourth weeks; if treatment is not continued further it results in a probable cure of not more than 25 per cent. of the cases. In this respect it corresponds with the antimony treatment, which is to be preferred in all possible cases.

Durban. F. G. CAWSTON, M.D.Cantab.

UNUSUAL HERNIA IN INGUINAL REGION.

THE following case is recorded on account of the unusual position of the hernia, which resembled those found in the epigastric region.

A man, aged 41, was raising a stone at his work on December 20th, 1926, when he felt a sudden pain in the left groin. He was taken home and examined by his doctor, who found an inguinal hernia the size of a hen's egg extending slightly into the scrotum. It was easily reduced.

The man was admitted to hospital, and an operation was performed on January 3rd. Examination prior to operation failed to detect a hernia, but an indefinite swelling was noted in the region of the external ring.

At the operation the external oblique aponeurosis was slit up and the canal displayed. No hernial sac was discovered, but a considerable quantity of extraperitoneal fat was present; this was removed. On retracting the upper lip of the external oblique aponeurosis upwards and inwards a mass of extraperitoneal fat was seen. It came out of an opening in the abdominal wall, the size of a cedar-wood pencil. It was just lateral to the rectus sheath, and half an inch above the pubis. There was a process of peritoneum in the fat, but no abdominal contents. The sac was ligatured and the opening closed with a mattress suture.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

GLOUCESTERSHIRE BRANCH.

Gastric Carcinoma.

AT a meeting of the Gloucestershire Branch on February 10th, Dr. J. RUPERT COLLINS in the chair, Mr. ARNOLD ALCOCK opened a discussion on the diagnosis and treatment of carcinoma of the stomach.

Mr. Alcock emphasized the difficulty of diagnosis. He pointed out that the chief seats of malignant growth were the breast, uterus, and stomach. Though in the first two the signs were discernible, yet the results of treatment were very poor. The stomach presented a much more difficult problem. Three types of gastric carcinoma could be distinguished: (1) The indurated ulcer, found as a rule in the lesser curvature, and of much the same type as simple gastric ulcer. Probably carcinoma did not develop from a simple ulcer so frequently as might be expected. Nine-tenths of cancers of the stomach were not preceded by ulcer. (2) The spreading type, encircling the stomach and giving rise to the leather-bottle stomach in its late stages. This was really an advanced example of the first type. (3) The fungating ulcer, which, spreading in the submucosa to start with, invaded the lymphatics, and soon passed out of reach in the portal area. The mediastinum was often infected, and hard glands might be found above the clavicles. Loss of appetite was very suspicious in a patient previously healthy. Sour eructations were complained of, and were frequently offensive. As a rule vomiting was slight in amount and it was rare to see blood. Loss of weight was often rapid, and was an important symptom. Blood might be demonstrated in the stools. Exploration should be undertaken when these symptoms were present. Abdominal tenderness was present before any lump could be felt. Moynihan was quoted as giving three indications for operation: (1) All cases with chronic ulcer over 40 years old, (2) if gastric stasis was present (delay of ten to twelve hours), (3) all cases of tumour. The surgeon was frequently disappointed when he opened the abdomen. Even when an early case had been expected there might be nothing to do but to shut up the abdomen again. In cases with a history of only a few months at the operation the condition might be found to be beyond treatment. The actual surgical procedure consisted in excising as much of the stomach as possible, with the lymphatic glands in the lesser curvature. Early diagnosis was of supreme importance, and at the same time presented much difficulty.

Dr. D. E. FINLAY said that as regards getting cases earlier he was sure there had been a great advance since twenty-five years ago, when diagnosis was so often delayed till there was a palpable growth. One source of error in coming to an early and correct diagnosis was the question of age. Malignant growth was possible even at an early age; his youngest patient had been a woman aged 22. In reviewing his cases the symptom on which he would put most stress was failure of appetite or even an actual distaste for food; in some cases this amounted to nausea. This was present for a considerable time before loss of weight. Indeed, many patients had not lost weight when the symptoms had aroused suspicion of malignant growth. Definite vomiting was a later symptom; many cases did not present it. Anaemia and other such signs were found to be really late when the history was carefully taken. In his

cases there had been no long history of indigestion; most patients had very short histories. He mentioned one notable exception—a man who had a long history of indigestion and vomiting. He was thoroughly overhauled in hospital with a negative result, but eighteen months later he was readmitted, and on the abdomen being opened an inoperable carcinoma was found. Dr. Finlay had been very disappointed by *x*-ray and chemical investigations. Dogmatic statements emanated from the *x*-ray department, but when the abdomen was opened great divergences were found from what had been expected. Trouble in the region of the stomach, leading to filling defects shown by *x*-rays, explained some of the fallacies. Chemical investigations had produced similar disappointments. The absence of hydrochloric acid was not worth much, nor the demonstration of occult blood. For really early diagnosis he laid most stress on loss of appetite, nausea, and possibly loss of weight. It was necessary to think carefully before jumping to the conclusion that the stomach was at fault. He had seen mistakes arise from missed tubercle, diabetes, and syphilis. It had been suggested that venous thrombosis occurring in the body might be an early symptom of malignant growth. He had recently had a case which might bear that interpretation. No medical treatment could cure, but in inoperable cases symptoms were diminished by pepsin preparations and hydrochloric acid. Washing out the stomach was often useful.

Dr. E. N. DAVEY, dealing with the chemical tests, admitted the difficulty of the laboratory worker, and the most claimed was that if the chemical findings were properly correlated with the clinical findings they were of some value. The two tests on which reliance was often placed were the test meal and the discovery of occult blood; both were of problematical value. Even when a growth was present only a very small proportion of the total mucous membrane might be damaged and a normal finding might result. The fractional test meal was the only one of practical value, but the patient must be properly prepared. He should be on light diet for one day. In the evening he had a glass of milk with two drachms of charcoal, and the test was performed next morning. The stomach must be completely emptied and the total volume of the fasting juice ascertained. In the fasting juice a great deal of evidence was to be found; obstruction might be diagnosed at once, and absence of HCl with a great increase in the acids of putrefaction was in favour of carcinoma. The presence of blood was an indication for intervention. The stomach was long in emptying in carcinoma. In one and a half hours there should be loss of acidity, but this was not found in carcinoma of the pylorus. Dr. Davey pointed out that the hyperacidity found in ulcer cases was due to the ulcer condition—a result and not a cause. As regards occult blood in the stools, its value was lessened because as a rule the patient was not properly prepared. He ought to be kept on a purely milk diet for at least three days, the diet must be free from meat and chlorophyll. Then charcoal should be administered, and when that had appeared in the stools the next specimen should be taken for examination. The presence of occult blood after these precautions, and in the absence of any bowel condition, indicated either simple ulcer or carcinoma of the stomach, but gave no help in distinguishing between the two.

The discussion was adjourned to the next meeting.

Clinical Cases.

Dr. JOHN GREENE described two cases of adiposo-genitalis which he had under treatment, and demonstrated one—a boy aged 8 years and 7 months. The case showed all the classical symptoms, including enlargement of the sella turcica, revealed by *x*-ray examination. One of the patients had a slipped epiphysis at the head of the femur, and this condition was discussed in detail by Mr. STALLMAN. Dr. GREENE reported that administration of pituitary anterior lobe tablets had apparently produced improvement, the boy of 8 years showing a loss in weight from 7 st. 10 lb. to 7 st. 7 lb.; the abdominal girth had been reduced two inches. Dr. Greene expressed some surprise at the improvement, as he had not really expected it.

Reports of Societies.

DIVERTICULA OF THE ALIMENTARY CANAL.

AT a meeting of the Harveian Society, held at Paddington Town Hall on March 10th, with Dr. E. LE FEVRE PAYNE, the President, in the chair, the Harveian Lecture was delivered by Sir BERKELEY MOYNIHAN, Bt., who took for his subject "Diverticula of the alimentary canal."

Harveian Lecture.

Sir Berkeley Moynihan described a diverticulum as a wayside track from a main path. In the alimentary canal a diverticulum was due to a protrusion of the mucous membrane from the lumen of the bowel, and in this protrusion other coats might take part or might not. The extrusion of the wall of the intestine was an essential step in the formation of several organs whose functions were associated essentially with the work carried on in the digestive tract. Thus the liver and the pancreas arose as buds from the wall of the intestine. But not all the little pouches springing from the mucosa came to this full development. The lecturer then spoke of three different degrees in development. In the first place, the diverticulum might develop in foetal life and proceed on its normal career, leading to the growth of the liver and pancreas (whose connexion was maintained with the alimentary canal through their ducts), or of the appendix (whose connexion throughout its length was fully maintained, with no differentiation into a duct), or of the thyroid gland. The lumen of the protrusion from which a large part of the thyroid gland developed did not go deeply into the solid bud which consisted of cells forming the thyroglossal tract; the foramen caecum on the dorsum of the tongue was the only patent part of the diverticulum. In the second place, the diverticulum might develop normally in foetal life, but its connexion with the mucosa in the adult might remain only in a curtailed condition, or it might finally disappear. He mentioned the diverticulum of Meckel found in the lower part of the ileum; this was the unclosed part of the omphalo-mesenteric duct. Again, the pouch of Rathke, seen in early infancy, vanished as a rule completely in the course of a few years. Finally, the diverticulum might develop and in normal circumstances disappear in foetal life, though in a few instances this normal atrophy and disappearance might not take place, and the diverticulum be found in the adult. Lewis and Thyng in the United States had found that diverticula from the stomach, duodenum, and jejunum were frequently found in foetal life, and at their tip little solid masses of cells were seen identical with the cells from which the pancreas grew. These cells normally withered and were absorbed, and it would seem as though a whole series of efforts were made to develop the pancreas, only those connected with the ducts of Wirsung and Santorini surviving. The others were there in case of mischance. In a few such cases the normal disappearance did not occur, and gastric, duodenal, or jejunal buds, with an accessory pancreas attached to each, might persist into adult life.

The various forms of diverticulum which occurred might be classified in three groups: (1) A diverticulum which arose as a bud from the wall of the intestine during development would contain all the coats of the bowel at that point; it was said to be "congenital" in origin and "true" in structure. (2) A diverticulum which occurred after development was complete, and was due to some abnormal process, would be found to contain, as a rule, only the mucous coat, with or without an adventitious fibrous layer, and in no case did it display all the intestinal coats; this was "acquired" in origin, and "false" in structure. (3) An acquired diverticulum might be caused either by the pushing out of the mucosa from the lumen owing to increased intestinal pressure, or it might be dragged out from the wall by the adhesion of some firm structure to the outer side of the bowel; in the former case it was a "pulsion diverticulum," and in the latter a "traction diverticulum." A diverticulum caused by the traction of an adherent structure to the outer side of the

alimentary canal, as, for example, in the oesophagus, might enlarge because of the pressure of increasing quantities of retained substances within its cavity. Beginning as a traction diverticulum, its enlargement was due to conditions similar to those which created and enlarged a pulsion diverticulum. Another form of diverticulum, the "traction-pulsion diverticulum," might therefore be described.

The lecturer next described and illustrated the changes which might occur. These included: inflammation in and around the sac—that is, diverticulitis and peridiverticulitis; suppuration; sloughing and gangrene; perforation to the surface, to a serous cavity, pleural or peritoneal, or to another viscus; adhesions which led to the compression and withering of the sac, or, in the case of Meckel's diverticulum, leading in one way or another to intestinal obstruction; development of carcinoma, and, finally, rotation of the sac when it had grown to such a size as to develop a neck or pedicle, this rotation, together with the pressure of the distended sac, causing obstruction. Pharyngeal diverticula were frequently described as oesophageal. On careful examination, however, and dissection of *post-mortem* specimens, it would be seen that the point of formation was the middle part of the inferior constrictor and the area known as the cricopharyngeus. Such pouches he did not regard as uncommon. They caused difficulty in swallowing on account of the swelling in the neck, and, when speaking, such people projected puffs of air between the syllables. Diagnosis by *x* rays was usually easy. He thought it was always best to remove these pouches by operation, and he illustrated with lantern slides the procedure he favoured. Diverticula occurred mostly at parts of the bowel where the wall was pierced by a blood vessel, weakening occurring in consequence of this piercing. He was quite clear that diverticula might exist without reducing the lumen of the bowel. For people with intestinal diverticula he recommended the taking of plentiful supplies of paraffin and a weekly dose of a stiff aperient.

Replying later to a vote of thanks, which Sir D'ARCY POWER proposed and Sir WILLIAM WILLCOX seconded, Sir BERKELEY MOYNIHAN spoke of the cancer campaign which had had such a good send-off in Yorkshire. His ambition was to enlist every medical man as an ambassador for this cause.

ECTOPIC PREGNANCY.

AT a meeting of the North of England Obstetrical and Gynaecological Society, at Sheffield, on February 25th, with the President, Professor FLETCHER SHAW, in the chair, Professor DOUGAL (Manchester) gave a review of 100 cases of ectopic pregnancy.

Professor Dougal said that he had operated on 100 patients for ectopic pregnancy during the last seven and a half years; in 5 instances a second operation for a similar condition was required. The pregnancy was situated in the Fallopian tube in 103 cases. In 2 cases of infected haematocele only the posterior fornix was opened. In the vast majority pregnancy was early; in only 2 cases had the foetus reached two months' development. In 94 cases tubal mole was present (76.5 per cent.), and the pregnancy was on the right side in 59 per cent. The terminations observed at the time of operation were: tubal abortion (52 per cent.), tubal rupture (37 per cent.), unruptured (12 per cent.). In four cases it was impossible to give an opinion, and both rupture and abortion were noted in one case. In 66 per cent. the condition arose between the ages of 26 and 35; the youngest patient was 21 and the oldest 43. The greatest number of cases occurred during the first five years of married life, but a large proportion occurred during the second five years. In 8 cases the patients had been married one year or less, and in all of these the ectopic was the first pregnancy. Evidence of pelvic infection was noted in only one of these cases. Nearly one-third of the patients had never had a previous uterine pregnancy. Taking the normal interval between successive pregnancies as not more than three years, the interval was unduly long in 55 per cent., and exceeding five years in 31 per cent. The shortest interval was seven months in one case. The chief predisposing cause of extrauterine pregnancy was undoubtedly a previous pelvic infection which so damaged the Fallopian tubes as to obstruct or delay the passage of the fertilized ovum to the uterine cavity. Developmental abnormalities and distortion of the tubes might have a similar result, but occurred less frequently. In certain cases, as in gonococcal conditions, evidence of old infection could only be seen microscopically in the mucosa of the tubes. In this series old-standing adhesions were present in 50 per cent. of cases. The opposite tube was converted into a hydrosalpinx in 7 cases, and a pyosalpinx in one case. The only developmental abnormality met within this series was a bicornuate uterus; the pregnancy was situated in the right tube, and terminated by abortion. Fibroids were seen in 2 cases. The diagnosis rested on a symptom complex which included one or more of three cardinal symptoms: amenorrhoea (72 per cent.), irregular uterine haemorrhage (92 per cent.), and abdominal pain (97 per cent.); pain on defaecation was also an important symptom. Shoulder pain was usually associated with ruptured tubes where the peritoneal cavity was suddenly flooded with blood. Irregular uterine haemorrhage was associated with the separation of uterine decidua, but not invariably, since it might persist after the complete expulsion of decidua or curetting, and might then be due to presence of living chorionic villi. Abdominal pain, generally sufficient to indicate to the patient that something was wrong, might be lancinating, colicky, or diffuse. The site of pain usually indicated the site of the pregnancy. Amenorrhoea, uterine haemorrhage, and abdominal pain were present together in 64 per cent. of cases; bleeding and abdominal pain together in 24 per cent. Amenorrhoea and abdominal pain were found in about 4 per cent., amenorrhoea and bleeding in 3 per cent., and pain alone in 3 per cent. The cases might be divided into three groups or clinical types. (1) The ovum remained in the tube, and there had been little or no haemorrhage into the abdomen. There had been 14 cases in this group, or 13 per cent. (2) Rupture or abortion occurred with diffuse intraperitoneal haemorrhage. There had been 29 cases of this type, or 27.6 per cent. (3) Rupture or abortion had been associated with gradual or repeated haemorrhage into the abdomen. This was found in 62 cases, or 60 per cent. Treatment was surgical, and the sooner it was started the better the outlook. It was impossible to foretell when another, and possibly fatal, haemorrhage would occur. In the very severe cases, where the patient was pulseless and in profound shock, the operation might be delayed for a time while treatment was directed to the shock, but after relieving it the operation should be undertaken immediately. There was no disease of like severity where the response to prompt surgical treatment was so rapid and so satisfactory. There were no deaths in his series. Of the patients traced who had been operated on more than six months previously the results were: subsequent uterine pregnancies, 46 per cent; subsequent ectopic pregnancies, 13 per cent.; no subsequent pregnancy, 41 per cent. The prognosis as regards subsequent uterine pregnancy was fairly good, but there was a serious risk of the patient having a second ectopic pregnancy. In this series 7 patients had two ectopic pregnancies, 5 of the patients having had both operations performed by the speaker.

Dr. LACEY asked if there was any history of infection in the puerperium in these cases; he thought that shoulder pain was usual. Dr. KING considered that rectal pain was more common than shoulder pain. He strongly advised waiting in the very severe cases till the accompanying shock had been treated. He did not regard the other cases as urgent at all.

Dr. LEITH MURRAY had recently studied his series of cases, numbering 112. He found them more common on the right side (67) than on the left (45). He did not agree with Professor Dougal as to the terminations; in his own series the intratubal ruptures greatly exceeded the tubal ruptures, the figures being: intratubal rupture, including mole abortion, 105, primary peritoneal rupture 1, secondary peritoneal rupture 4, intraligamentary rupture 2. He agreed that in the majority of cases there was evidence of pelvic disease or a history of antecedent infection. He was of the opinion that disease of the appendix might be

a common predisposing factor, accounting in the first place for the preponderance of cases of pregnancy on the right side. In these cases he had removed numbers of apparently normal appendixes, and on microscopical examination had found them diseased. In his series a history of amenorrhœa was less often elicited, and pain was not so marked a feature.

Dr. CROFT said that in his experience amenorrhœa was not so marked a symptom, and the pain was generally in the abdomen, in some cases being situated elsewhere than over the lesion. Dr. A. A. GEMMELL asked if there was any evidence of an increased number of abortions preceding these ectopic pregnancies, as in Germany it had been thought that ectopic pregnancies had increased with the increase in criminal abortion during the war. Mr. ST. GEORGE WILSON had used transfusion with the patient's own blood in a case of uterine rupture, with satisfactory results. Mr. W. GOUGH agreed as to early operation. Professor MILES PHILLIPS had recently collected 150 cases, with 3 deaths, and thought that in a number of cases ovarian disease or disfunction was a factor. The PRESIDENT remarked on the supposed preponderance of ruptures over tubal abortions, and, like Dr. LEITH MURRAY, had found the reverse to be true. He had operated on patients with normal tubes but cystic ovaries, and considered ovarian disease as a factor in the etiology.

Professor DOUGAL said that he had no complete details of previous puerperal infection, but he had notes of cases with previous abortions. He did not agree with delay in operation in any type of case, and added that the symptoms in unruptured cases were quite definite. He agreed as to the large number of cases of ectopic pregnancy on the right side. He had operated on patients from whom the appendix had been removed previously. In some cases it was difficult to decide whether there was rupture of a tube or an abortion. He had not tried transfusing the patient with her own blood. He thought that the ovaries might sometimes be at fault.

Intraligamentary Fibromyoma.

Dr. LEITH MURRAY (Liverpool) described a case in which an intraligamentary fibromyoma had been removed from a patient aged 60.

The patient was married and had had three children, the last twenty-three years previously; she had ceased to menstruate at the age of 45. She had complained of pain and swelling in the abdomen for a year, and pain radiating down the right leg for four months. She had been confined to bed for five weeks when first seen. Laparotomy revealed a simple oedematous fibroid within the right broad ligament, lifting up the uterus. There was bullous oedema in the capsule, but no difficulty was experienced in enucleating the growth. The cavity was closed by sutures, and uninterrupted recovery followed. The specimen shown weighed 7 lb. 8 oz.

Dr. Leith Murray said that in his experience fibroids rarely caused symptoms in the menopause. In 540 consecutive operations for fibroids fourteen had caused symptoms in the menopause—that is, 2.6 per cent. Oedema of the fibroid was the usual cause of post-menopausal symptoms.

The PRESIDENT remarked on the small number of post-menopausal fibroids in Dr. Leith Murray's series. He had seen many cases of fibroids which had caused symptoms after the menopause. Mr. W. GOUGH remembered a case in which a fibroid in the menopause gave rise to symptoms, owing to shrinkage. It had previously rested in the abdomen, and when it shrank it fell into the pelvis, causing retention of urine.

Congenital Absence of Vagina and Cervix.

Dr. LEITH MURRAY also reported a case of congenital absence of the vagina and cervix.

"A girl, aged 15, was sent to hospital with a history of abdominal pain lasting two years. The pain was colicky in character; it occurred every four to five weeks and lasted, on each occasion, about five days. She had a feeling of much weight in the pelvis at those times and frequently vomited. There had been no menstruation. Examination under an anæsthetic showed a vulvar depression, which just admitted the top of the index finger; this was all that could be found to represent a vagina. The vulva and the site of the urethral orifice were normal, and the breasts and pubic hair well developed—the former unusually so for her age. On bimanual rectal examination no thickening such as would suggest a vagina could be found. The uterus appeared to be normal in size and position; the right ovary was readily palpated. At a perineal exploratory operation the pelvic connective tissue between the urethra and the bladder in front and the bowel behind was easily opened by a finger, after incision at the apex of the vulvar depression. The lower pole of the uterus could just be reached, but was not brought down by volsellum lest injury to the bladder or bowel resulted. No suggestion of any vagina was found. The girl was kept in hospital for observation during her next periodic pain. The attack was an obvious colic, associated with abdominal pain, tenderness, and backache; it lasted four days and the patient was then very languid and tired. The uterus was removed, together with the left appendage. The fundus of the uterus was adherent to the bladder and there was a small quantity of black, uncoagulated blood in the pelvis. Both appendages were lightly adherent, particularly around the tubal ostia. It seemed likely that blood had on occasions been regurgitating into the peritoneum. Each ovary appeared normal and neither was enlarged; the uterine body was firm and not appreciably abnormal. On cutting across the broad ligaments, as soon as the uterine arteries had been divided, the uterus was completely released by finger pressure. The lower pole bore no resemblance to a cervix and was uncovered by epithelium. The sudden release of the uterus after section of the broad ligaments was most noticeable and quite unexpected; this may have been due, in some degree, to the preliminary exploration. The length of the uterus was 2½ inches. On opening the cavity about eighteen drops of dark fluid escaped; this was obviously under tension. The cavity thereafter was found to measure 1¼ inches; it ended blindly and the obturating bridge at its lower pole measured three-eighths of an inch. There was no evidence of dilatation of the Fallopian tubes. Sections showed no sign of cervical stroma or endocervix. The endometrium was practically normal throughout except at the lowest level, where a slight tendency towards polypoidal development was evident. The wall of the uterus and the obturating bridge appeared as a normal myometrium.

Dr. Leith Murray had failed to find in the literature any case exactly comparable to this. According to Keibel and Mall the tubar portion of the uterus formed the corpus uteri, and the utero-vaginal canal the cervix and vagina; the development of these two was therefore to some extent independent. It seemed remarkable, however, that the demarcation between the distal three-quarters and the remaining quarter of the whole uterine and vaginal tube should be so complete as was evident in this case.

Mr. STACY said he had reported an almost similar case to the Anatomical Society in 1924.

Adhesive Vulvitis.

Professor DOUGAL read notes of a case of adhesive vulvitis.

The patient was 36 years of age, married ten and a half years, and a nullipara. Menstruation had been normal. Eight years previously, during a severe attack of pneumonia, she began to complain of irritation in the neighbourhood of the vulva, and stated that the "vagina healed up." Intercourse had not been possible since, and recently she had had difficulty in micturition. Six years ago she had been curetted, and the adherent labial folds separated, but she had been no better. On examination the labia minora were found completely glued together in the mid-line, except at a point about the middle of the vulva, where a small opening, one-eighth of an inch in diameter, served for escape of menstrual blood and urine. Under an anæsthetic it had been found possible to separate the adherent folds without difficulty, and during separation a thin layer of desquamated epithelium was partially torn away, and remained stretched across the vulval opening. The area affected consisted of the inner surfaces of the labia minora and the folds about the clitoris. The surfaces were disinfected and separated by a dressing, but in a few days became adherent again, so the vulva was excised and the vaginal orifice well opened up, no labial surfaces being left in contact. Two months afterwards she was quite well, and there was no recurrence. Sections of the skin showed inflammatory changes in the deeper layers, and thickening and keratinization of the squamous-celled layers.

Professor PHILLIPS asked if Professor Dougal thought the infective agent was the pneumococcus. He himself had seen a case of pneumococcal endometritis in pneumonia. Professor DOUGAL agreed that the condition was probably due to the pneumococcus.

Foreign Body in a Pregnant Uterus.

Dr. LACEY reported a case of a foreign body in the pregnant uterus.

The patient, aged 28, with one previous instrumental confinement, had had amenorrhœa for two months. She said she felt a lump in the vagina, and tried to push it back with a crochet hook, which disappeared. She had pain in the lower abdomen the same night. On admission to hospital two days later she had a slight show, and a temperature of 100.6°, pulse 96. The os was closed; the uterus was three and a half to four months in size. She was æ-rayed, and the radiologist reported the presence of a foreign body, presumably in the uterus, and no fœtal parts. On the next day she aborted, her temperature being 101.6° and pulse 108. On the following day there was diffuse abdominal pain; the abdominal wall was tender and rigid, and there was slight distension. On laparotomy there was a small quantity of odourless pus in the abdominal cavity. The crochet hook was protruding through the

posterior wall of the uterus, and was firmly embedded against the sacrum. It was removed with little difficulty. The abdomen was drained, and the patient made an uninterrupted recovery.

The PRESIDENT inquired as to what action should be taken in these cases with regard to reporting them to the police. Dr. LEITH MURRAY said that he had had a case of premature twins in which he suspected criminal abortion. He had been advised to do nothing in the matter unless the patient died. Dr. BRIDE had removed two crochet hooks from the abdomen, one from the right kidney pouch and the other from the pouch of Douglas; in neither of these cases was the patient pregnant, though this was suspected. One of the cases was already in the hands of the police, but, when informed that the patient was not pregnant, they took no further action. Dr. CROFT had had a similar case, and he had removed the foreign body after the abortion.

Cystic Tumours of the Ovaries.

Miss NICHOLSON (Liverpool) described a case of cystic papillary tumours of the ovaries.

The patient, aged 44, married eighteen years, and a nullipara, complained of swelling of feet and legs for four months. She had always had scanty menstruation, and amenorrhoea during the last four months. Both legs and thighs, especially the right, were oedematous. A mass, from which the uterus could not be distinguished, was felt filling the pelvis, and rising as far up as the umbilicus. Laparotomy disclosed a large ovarian cyst filling the pelvis and lower abdomen; the bladder and coils of intestine were densely adherent to it. In freeing a small part of gut the cyst wall ruptured, and about a pint of slightly viscid straw-coloured fluid was evacuated. Multiple papillary growths were seen in this cyst, which was seen to be a loculus of a multilocular cyst. It was deemed impossible to remove the growth, so a small piece was excised for microscopic examination, the cyst wall was sewn up, and the abdomen closed. The patient made a good recovery. Microscopic examination of growth showed a simple papillary arrangement of cells, with marked myxomatous degeneration of the ends of many of the papillae. There was no evidence of malignancy. The patient was having *x*-ray therapy; the oedema had gone, and she was menstruating, but the abdominal tumour was only slightly reduced.

Miss Nicholson said that in her experience it was unusual to meet with such numerous and dense adhesions in cases of ovarian papillary cyst adenomata.

The PRESIDENT agreed that such dense adhesions were rare. He asked if there was any history of previous infection of the ovaries, suggesting that the adhesions might have been present round ovaries attached to the growth. He was doubtful as to the prognosis to give in these cases. He had recently seen a case on which he operated four years ago, in which the peritoneum was studded all over with small growths. The patient had had *x*-ray treatment, and had returned with two small recurrences apparently in the abdominal wall.

Professor DOUGAL recalled a patient on whom he had operated, and from whom Dr. Leith Murray had taken away a papilliferous cyst five years previously. He succeeded with great difficulty in removing another papilliferous cyst and the uterus, with good results.

Miss NICHOLSON said that the growth was apparently quite simple. There was no history of previous infection. She thought that the patient would have died if removal of the tumour had been attempted.

VERSION IN OBSTETRICS.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society, the President, Dr. E. RIVAZ HUNT, in the chair, Mr. H. F. SEYMOUR read a paper on version in obstetrics, the steps of Potter's method of version being demonstrated by lantern slides.

Mr. Seymour said that there was still a lamentable lack of hospital beds for obstetric cases for the reception of poor women whose homes were unsuitable for the conduct of labour, for the proper instruction of students and midwives, and for research work in this most important branch of preventive medicine. He traced the development of version through the centuries from the time of Soranus, the father of midwifery, and referred to the book of Eucharius Rösslin, published in Worms in 1513, and the lucid description of internal podalic version by Ambroise Paré in 1550. Smellie's work in England was described, and the later developments down to the time of Braxton Hicks, who introduced bipolar version. Dr. Seymour then discussed external version for rectifying a faulty lie before labour had started; bipolar version, a difficult manœuvre but useful in lateral or marginal placenta praevia for bringing down a leg for exercising pressure by means of the half breech; and internal podalic version, with special reference to the technique of Dr. Potter of Buffalo, New York. Mr. Seymour considered that Dr. Potter's system of internal podalic version was a beautiful example of the obstetric art, well worked out and conceived. It had the following advantages over the usual way of performing an internal podalic version: the very careful slow dilatation of the vaginal introitus and vagina; by bringing down both feet, instead of one, there was much better control; the rotation of the child so that each shoulder was delivered, in turn, as an anterior shoulder, saved lacerations of the perineum; leaving the head on the perineum, after the mouth was born, and delivering very slowly also tended to save the perineum. He was unable to agree, however, with Dr. Potter's too frequent use of the manœuvre, and said that it could not be right to deliver all women by version when the os was fully dilated, which would undoubtedly be meddlesome midwifery. He preferred to limit the use of internal podalic version to its positive indications—namely, transverse presentations; prolapse of the cord; in face, brow, and unreduced occipito-posterior presentations, when the head was not entering the pelvic brim well; in lateral or marginal placenta praevia, when it was the best mode of delivering; in cases of moderately contracted flat pelvis, when it was safer for the child than a high forceps delivery; and as a method of rapid delivery where indicated by maternal complications or foetal distress when the cervix was three-quarters dilated, the pelvis normal in size, and the head not engaged. When the head was fixed in the pelvic cavity, due to disproportion between it and the size of the pelvic cavity, it was necessary to deliver the after-coming head by means of forceps, and those designed by Dr. Piper of Philadelphia were recommended. These forceps were extremely long, the cephalic curve was that of a light Tarmier, and the shank was at least twice as long as that of other forceps; there was no shoulder, and the shank was so curved that the handles dropped below the patient's thighs. They rendered extraction very easy and were as useful in breech cases as after a version. Dr. Seymour considered that civilization had tended to make labour more pathological, and he wondered whether the increased athleticism of growing girls would in the future produce in women the male type of pelvis, with its obstetrical disadvantages. He thought that the accoucheur should mitigate suffering as far as possible. Before the os was fully dilated the only possible relief was to administer opiates; Dr. Fairbairn had recently appealed for the extended use of this treatment. Scopolamine-morphine narcosis was useful in some very nervous patients. If it was necessary to give an anaesthetic for the extraction of a tooth, surely it was good practice to alleviate thus the pains of the second stage of labour. Chloroform was the best anaesthetic for midwifery on the whole. There was no harm in gently easing the head over the perineum with the forceps, under anaesthesia, the utmost gentleness being used and the strictest antiseptic technique being employed. Where there was no contra-indication, and the patient was under chloroform, pituitrin would do the work of the forceps. When a woman of 44 or 45 years became pregnant for the first time the advisability of Caesarean section should be carefully considered. In the conduct of midwifery, while there should be no interference with the natural process of labour, yet everything possible should be done to make things easier and more bearable for the patient so long as her risk was not increased.

OSTEOMYELITIS.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on February 18th, the President, Mr. ANDREW FULLERTON, in the chair, Sir WILLIAM WHEELER showed a patient, aged 25, who had been operated on eighteen years previously for osteomyelitis of the lower third of the femur.

Sir William Wheeler said that he had removed the lower third of the femur by dividing it with a Gigli's saw above the disease, and by wrenching away the metaphysis at its

junction with the epiphysis. This operation had been performed before the publication of Sir Harold Stiles's paper on removal of the diaphysis of the long bones. He also showed lantern slides of the portion of bone removed, illustrating the anatomical perfection of the re-formed shaft. The patient had full movements of the knee-joint, and there was three-quarters of an inch shortening. At the time of operation there had been a sinus discharging in the popliteal space. Sir William Wheeler said that Stiles had advocated the operation of subperiosteal excision of the diaphysis, which sometimes included the whole shaft in all the long bones with the exception of the femur, but the present case made it clear that the operation could be performed on the femur with the same success, and that there was no fear of undue shortening. He had reported three cases of resection of the juxta-epiphyseal portion of the femur in 1913. The bone removed in the present case showed admirably the central focus and the osteoplastic periosteitis. The formation of the thin layer of porous bone, coupled with the presence of thickened periosteum, was responsible for the very important clinical sign seen early in these cases—namely, thickening. The pathology of this and allied conditions could be explained on an anatomical basis, and was in consequence simple. Three sets of capillaries met in the metaphysis of bones: (1) the end branches of the nutrient artery (diaphyseal group); (2) branches from the arteries supplying the joint entering the metaphysis (metaphyseal group); and (3) branches from the same source as (2) supplying the epiphysis (epiphyseal group) perforated the cartilage and anastomosed with the diaphyseal and metaphyseal vessels. The circulation through the cancellous spaces of the bone was slow, and this fact, combined with the free capillary anastomosis, made it obvious why the site was favourable for the deposit of a tuberculous embolus. A slight injury, breaking down some of the trabeculae of the cancellous spaces, might determine the onset (by setting free an embolus) of active tuberculosis. Once established, the disease was at first frequently central, and subsequently was carried by the Haversian systems through the compact bone to the periosteum. An osteoplastic periosteitis ensued, and a thin layer of new bone, very porous and delicate, was laid down between the thickened periosteum and compact bone. Finally, as caseation and liquefaction proceeded, an abscess formed in the soft tissues, and was followed by a sinus leading down to diseased bone. Many of the cases were probably of mild staphylococcal origin, and were not tuberculous. Sir William Wheeler thought that Stiles's paper was epoch-making, and had greatly simplified the teaching in connexion with osteomyelitis.

Mr. A. B. MITCHELL said that the restoration of the bone in this case had been remarkable. He thought that all surgeons were afraid of performing this operation on the femur, partly because of Sir Harold Stiles's paper on the subject, and partly because they feared that it would leave the patient with a short leg.

Mr. SETON PRINGLE said that he had seen this patient with Sir William Wheeler, and as a result had performed the operation three times since, and intended to continue its use. It was an operation which should only be employed in selected cases.

The PRESIDENT said that he had only performed this operation once, the patient being a girl with a suppurating sinus, when he had found the bone loose and had pulled it out. She had a severe attack of toxaemia. He thought that when curetting was tried in these cases a toxaemia resulted sometimes which turned the result of the case against the patient.

The Appendix Reflex in Migraine.

Mr. A. B. MITCHELL read a paper on the appendix reflex as a cause of migraine and other troubles. The paper was illustrated by reports of cases, and Mr. Mitchell stated that the condition had been relieved following the removal of the appendix even though this organ was not grossly diseased.

Mr. DENIS KENNEDY thought that some of Mr. Mitchell's cases were attributable to toxaemia. Arbuthnot Lane had said that practically every disease was due to intestinal toxaemia, and that for this condition the whole colon should be removed. Mr. Kennedy thought that most patients who suffered from appendicitis had constipation, and that after appendicectomy the constipation disappeared very rapidly. He believed that the appendix contained enough poison to produce most of the symptoms described by Mr. Mitchell, if it was not emptying itself into the colon as it should; in this type of case its evacuation was certainly imperfect.

Dr. G. E. NESBITT doubted the value of the appendix reflex, and added that if Mr. Mitchell's suggestions were correct, medical practitioners should advocate the advisability of removing the appendix in infancy as a routine measure. He thought that the occurrence of benefit after the operation reported by Mr. Mitchell was *post hoc* rather than *propter hoc*. He agreed that any foci of infection should be dealt with; if the focus was in the appendix this organ should be removed, but unless this was the case he would not perform appendicectomy.

Mr. R. A. STONEY had often encountered patients with obscure complaints, sometimes referred to the abdomen in the form of vague indigestion, and sometimes ascribed to migraine. In these cases at an operation appendix trouble was often found. After its removal improvement ensued in a large proportion of the patients. In such cases he thought that there was little more than *post hoc*, but there were some *propter hoc* cases. In doubtful cases where no other cause could be found, and where, after a careful examination, it was apparent that there were symptoms of trouble in the appendix, such as tenderness or thickening, it was certainly worth while operating and removing the appendix.

Sir WILLIAM WHEELER thought that Mr. Mitchell had made it clear that most of the patients who had come to him had had symptoms (even though remote) of appendicitis; some had had very definite symptoms. It was apparent to him that what Mr. Mitchell wished to emphasize was that in cases where the operation had been performed and the appendix had been found diseased the patient had greatly improved after removal. Mr. Mitchell had, he thought, proved that trouble in the appendix in a certain number of cases accounted for remote disturbances of a reflex or toxaemic nature.

The PRESIDENT regretted that Mr. Mitchell had not extended the scope of his paper, instead of singling out the appendix, since similar symptoms to those described by Mr. Mitchell might be caused by the gall bladder, which, when diseased, gave rise to all sorts of symptoms.

Mr. MITCHELL, in reply, said that he had meant to imply that it was possible for a patient to have a diseased appendix which might become rather easily overdistended, but still would have the power of emptying itself, and by doing so would not produce pain, but might give rise to severe nervous symptoms. This was not the case with all patients. Frequently patients had a movable or floating kidney which did not upset them at all, whereas in other patients this condition produced a curiously neurotic hysterical state. His patients had been under medical treatment for many years, and the reason for their ill health had not been found. In seeking a cause the abdomen should be considered very carefully, since a very large number of cases of chronic headache in women were due to a retroflexed uterus. He did not think that continued toxaemia could cause migraine and similar conditions, which were much more likely to be due to something which occurred suddenly. In cases in which the abdomen was opened, and the stomach was found to be healthy except for a somewhat thickened pylorus, a surgeon would think that the condition was a reflex one; he would look successfully for the cause lower down.

Dilatation of the Sigmoid.

Mr. DENIS KENNEDY showed a specimen of a dilated sigmoid taken from a woman, aged 55, who had been admitted to hospital with a provisional diagnosis of fibroid uterus. At the operation a huge sigmoid was found, with no constriction whatsoever below it. The patient had not suffered much pain, and there was no history of constipation; apart from a feeling of discomfort, she had complained of nothing, but had noticed the lump swelling for about twelve months. Mr. Kennedy had believed at first that he was probably dealing with a big mesenteric cyst.

The PRESIDENT thought this was a case of achylasia of the pelvirectal sphincter. It was possible for a similar condition to arise in the oesophagus and in the pelvic colon. If the pelvirectal sphincter was examined it would be found that its disposition was different from that of other portions of the intestine. It was possible, as pointed out by Hurst, to have achylasia of the pelvirectal sphincter and also achylasia of the anus. It might be possible to cure patients of this condition by stretching the pelvirectal sphincter and to avoid such a big operation as was necessary to take away such a large amount of the patient's intestine as Mr. Kennedy had had to remove. The President related a case in which this had been done with great success.

Mr. A. CHANCE considered the parallelism between achylasia of the oesophagus and ileopathic dilatation of the sigmoid colon due to achylasia of the pelvirectal sphincter of the greatest importance. He had effected cure in a case of achylasia of the oesophagus by digital dilatation of the cardiac end, and it was now well known that these cases yielded successfully to digital or instrumental dilatation. If the parallelism were true there was every hope that by dilatation of the pelvirectal sphincter cases of ileopathic dilatation of the colon, formerly so intractable to treatment, could now be cured.

Mr. C. J. MACAULEY thought the condition was undoubtedly achylasia of the retrosigmoid sphincter; the responsibility of this condition for Hirschsprung's disease had been suggested some years ago by the Mayos. It seemed to him that, although dilatation of the rectal sphincter in a child might be comparatively easy, it would be very difficult in an adult.

Mr. J. H. HAYDEN was at present treating a case of achylasia, and had found the greatest difficulty in dilating the lower end of the oesophagus at the first attempt. The patient obtained some relief after the first dilatation, but was now so ill again that it had been necessary to pass a tube several times during a period of seven or eight weeks. Recently, however, the patient had gained 2 st. in weight.

AT a meeting of the Nottingham Medico-Chirurgical Society, on January 20th, Dr. J. C. BUCKLEY gave his presidential address on the early diagnosis and treatment of syphilis. Dr. Buckley commented on the importance of early diagnosis and treatment of a disease so prevalent and so disabling, since thus the most severe results could be avoided. He laid stress on the necessity for the examination of any suspicious sore for the spirochaete, and gave details as to the technique of the examination by dark-ground illumination, mentioning that this should precede the application of any antiseptic to the sore. By this examination a positive diagnosis could be made before the Wassermann reaction became positive. He dealt briefly with the other tests for syphilis, and then detailed the routine treatment as administered at the Nottingham Venereal Diseases Clinic. The drugs in use were (1) novarsenobillon for intravenous, and (2) bismostal for intramuscular injection. The technique of the intravenous injection was described, and the complications of the treatment were detailed, the chief being local sloughing from faulty injections, dermatitis, and jaundice. In dealing with jaundice, the lecturer mentioned that since the van den Bergh reaction had been extensively used at the Nottingham Venereal Diseases Clinic the incidence of jaundice had been reduced by 50 per cent.

AT a meeting of the Sheffield Medico-Chirurgical Society, on February 24th, Professor ARTHUR HALL gave a lecture on the reflexes which determine and control posture. He defined the function of the low level reflexes, situated between the mid-brain and the medulla, as being the control of certain automatic actions, among which might be classed posture. He dealt first with those reflexes which helped to maintain an animal in a fixed normal position, and which he called "stance reflexes"; he then considered those which enabled an animal to reassume the normal position when this had been upset—the "righting reflexes." By means of a series of models Professor Hall demonstrated the various attitudes and postures which an animal might be made to take up in various experiments, and showed very clearly the effect on the limbs of the varying tonicity of neck muscles. A series of cinematograph films of dogs and other animals was shown, illustrating vividly the actions which were called into play by the "righting reflexes." A particularly interesting film showed the slow rotation of a duck's body through an angle of 180 degrees, during which the animal was seen to keep its head in a fixed position relatively to the horizontal; when a complete revolution had been made the bird suddenly reversed the position of its head, thus bringing it back to the same relative position in space.

JAMES MACKENZIE INSTITUTE.

ON February 22nd Dr. A. ROWAND read a paper on *oxaluria, with special reference to its occurrence in children*. He pointed out that the term "oxaluria" was of very vague significance. It might be applied generally to the presence of calcium oxalate crystals in the urine, or limited to cases in which they occurred in large numbers and persistently; it had been suggested that the term should be used to signify excess of oxalic acid excretion in the urine; and it was applied to conditions of impaired health associated with oxalate crystals in the urine. Oxaluria as a condition with clinical symptoms was first described about the middle of last century. Golding-Bird made an exhaustive study of the subject, and the symptoms he described have been handed down, more or less fully, from textbook to textbook, the majority of the writers having probably repeated the views of their predecessors without independent investigation. Dr. Rowand gave a chronological survey of the opinion expressed in prominent clinical textbooks from the days of Golding-Bird to the present time, showing that the tendency had been to put less and less weight on any possible causal connexion between the oxalates and the general symptoms, and to regard both as having a common origin in some disorder of metabolism. The possible sources of oxalates were various, and therefore it could not be said that the presence of oxalate crystals in the urine indicated one definite error of metabolism. Moreover, there were individual idiosyncrasies. Of two individuals on the same diet one might show a large deposit of oxalates in the urine, while in the urine of the other no oxalates were found, and this might be the case even when substances rich in oxalic acid, such as rhubarb, were being taken. Again, the occurrence of haematuria was apt to be regarded lightly if many oxalate crystals were present in the urine, but probably in a healthy urinary tract irritation by the crystals was unlikely to cause such a serious symptom. All writers laid stress on the danger of the formation of calculi, but this did not solely depend on the amount of calculous material in the urine. Benjamin Moore showed that in the core of a calculus some colloidal substance was present in association with the calcium oxalate. Dr. Rowand did not suggest that the occurrence of oxalate crystals in the urine of children was of greater significance than in the case of adults. But the large number of urines of children who came to the James Mackenzie Institute for periodic observation provided a valuable field for study. The urines were examined at every visit, and as they were voided at the institute it would be possible to determine the extent to which the presence of oxalate crystals in fresh urine was associated with symptoms of impaired health. The investigation had been in progress for about a year. Fourteen per cent. of the urines had shown oxalate crystals as against the 30 to 40 per cent. commonly stated as applicable to urines. This lower percentage might be due to the fact that all the urines were freshly voided, and that a large proportion of the children were in good health. In about 20 per cent. traces of protein had been associated with the oxalates. In a very small number of cases were red blood cells found. There was some ground for believing that not only the number but the nature of the crystals might be of special significance. Refractile particles and minute octahedra would appear to be especially associated with symptoms of disordered metabolism and impaired health. But the investigation had not gone far enough to justify any definite opinion on this matter.

Reviews.

ON MEDICAL CASE-TAKING.

EVERY teacher of medicine requires a framework on which to lay out the rudiments of instruction for those students who are beginning their clinical work. The small volume[1] by Professor KENNEDY represents the framework which he has found useful at Cardiff. At the outset we are struck by the way in which this book differs from most others of the same kind. As a rule these guides to clinical examination partake of the nature of railway time-tables in which the student traces out particular systems of the human body as a prospective traveller traces out his train through the pages of *Bradshaw* to its destination. Professor Kennedy does not provide the student with a guide of this sort; the student is not asked to sit book in hand with one finger following down the page a list of questions and with the other hand recording the patient's answers or his own observations. He would appear to intend his book to be read away from the patient's beside and left at home. It is interesting enough to be so used because it is concerned more with principles than with details. The first two chapters deal mainly with history-taking, and this part is not unduly laboured, as is too often the case in modern teaching, for in practice both patient and student are apt to exhaust themselves at the game of cross-questions and crooked answers. Professor Kennedy realizes that the amount of exact information a sick man can give about his history is severely limited, and he instructs his students to stick to points on which the information of the patient and his family may be expected to deserve attention and prove enlightening.

The kernel of the book is contained in Chapter III. The importance of looking at the outside of the patient before going on to speculate on his inside has rarely been more deftly emphasized. Hippocrates is obviously the inspirer of this chapter, in which his description of the facies of impending death is given verbatim. And so, piecemeal, the student is encouraged to survey the "picture" of his patient before proceeding to the physical examination by palpation, percussion, auscultation, instrumentation, and chemical and biochemical analyses.

In the later sections, where physical examination is described, the author is content with brief rules and possibly inadequate explanations. Still, there are other books to which the student can turn for more detailed accounts of the phenomena he may encounter. A bulkier book might prove far less readable and therefore less instructive. But the explanations of auscultation surely need to be more explicit. Professor Kennedy partly disarms this criticism by saying in his preface that the student is assumed to have acquired some preliminary knowledge of physical signs and laboratory methods before he begins clerking in the wards, but in a book which makes room for details of a chemical test for free hydrochloric acid in vomit some explanation of the exotic terms used in pulmonary auscultation might well be afforded. Speaking of terms and their meaning, we wonder when lividity first began to imply "cyanosis combined with pallor"; there is authority for the meaning "black and blue," but surely not for "white and blue."

However, we feel certain that as an adjunct to the preliminary course which the students receive this thoughtful book will meet with wide appreciation.

It is interesting to contrast with Professor Kennedy's concise remarks on history-taking a book[2] recently written by Dr. JAMES A. CORSCADEN of Columbia University, which is devoted entirely to the subject of taking and recording patients' histories. The first impression the book gives is that undue attention is paid to the patient's own analysis of his or her (the book is mainly gynaecological) disordered feelings. Then there occurs the sentence "the patient must be met on common ground of language and vocabulary," and light dawns. It has to be borne in mind that the official language of the United States is not the native language of large numbers of patients coming under treatment, nor is it by any means invariably that of the doctors. Thus it is not so surprising to find Part II consists of "practically a complete list of terms employed in describing human discomfort together with a list of such circumstances connected with the life of the patient as will aid in the diagnosis and management of his illness."

A book like this brings home clearly how far the difficulties the student encounters when he begins clinical medicine depend upon the use of foreign or archaic words varied by the intervention of a few modern bastards pretending to Greek or Latin parentage. Some will long for a return to the direct speech of the Anglo-Saxon leechdoms.

CLASSIFICATION OF CEREBRAL GLIOMAS.

DR. PERCIVAL BAILEY and Professor HARVEY CUSHING have issued an important volume, *A Classification of the Tumors of the Glioma Group on a Histogenetic Basis, with a Correlated Study of Prognosis.*[3] These tumours represent about 40 per cent. of all intracranial neoplasms, and their microscopical appearances differ widely. Further, the results after operative treatment vary remarkably in a manner which has not hitherto been adequately explained. The authors therefore undertook an investigation in order to discover the basis of the structural variations of these tumours and the significance of such variations in relation to the outlook after operative removal; in other words, in relation to the malignancy of the growths. They first addressed themselves to the detailed study of the structure of gliomatous tumours removed at operation or necropsy. They evolved a classification of these tumours based upon their cellular structure in relation to the normal histogenesis of the brain. They identified among the tumours types corresponding to practically every variety of normal brain cell, of which they distinguished twenty types arising at progressive stages in the development of the central nervous system. An account of the histogenesis of the brain, of the staining methods employed, and of the morphology of the normal cellular types is followed by a description of the histological appearances of the tumours, which occupies a large part of the book. The microphotographs which illustrate these sections are profuse and excellent.

The authors then turn to the second part of their investigation. Independently of the histological study a statistical inquiry was undertaken in regard to the total length of life from the date of onset of symptoms in 414 cases classified as glioma in the records covering a period of twenty-two years (1903 to 1924) of the Johns Hopkins and Peter Bent Brigham Hospitals. For various reasons 160 of these cases were rejected, and the remaining 254 were examined by modern histological methods and classified in the manner indicated. The general result of the inquiry showed that the tumours whose cellular structure reproduced the more primitive and less differentiated cells of the developing nervous system were much more malignant than those composed of more highly differentiated cells. Tumours of the latter type may be of extremely slow growth, and, unless their site is such as to cause obstructive hydrocephalus, may remain latent for many years.

The importance of this research in regard not only to prognosis but to the indications and extent of operative treatment is clearly very great.

JOHNSTONE'S "MIDWIFERY."

THE fifth edition of Professor R. W. JOHNSTONE'S now well known *Text-Book of Midwifery*[4] fully maintains the reputation it has deservedly acquired. It is compact, clearly written, and its teaching eminently sound and practical.

The reviewer, however, usually feels that he has to play the part of critic, and from this standpoint the impression given by this book is that its lay-out is rather too much on traditional lines. Though our conception of midwifery has been revolutionized in the last generation, this book does not fully express that change. It seems to be the old

[4] *A Text-Book of Midwifery for Students and Practitioners.* By R. W. Johnstone, C.B.E., M.A., M.D., F.R.C.S.E. Fifth edition. Edinburgh Medical Series. London: A and C. Black, Ltd. 1926. (Cr. 8vo, pp. xxviii + 503; 257 illustrations. 15s. net.)

design brought up to date where required by advances in science and practice. The four or five pages on ante-natal supervision, in which the form used at the Edinburgh Maternity Hospital is very properly included, might be enlarged in another edition in order to convey the great place this supervision now takes in practice. To make room the amount of space given to details and illustrations of rare forms of pelvic contraction might perhaps be reduced; one is described as an obstetrical curiosity, "there being only some dozen specimens known." Apart from what is an impression and no more, we have nothing but praise for the amount of matter compressed into the 500 pages of this book. It is full and brimming over.

Of its eight sections, the first four roughly cover the physiological and the other four the pathological side of obstetrics. The illustrations are numerous; they are for the most part line drawings that teach their lesson well, but there are also some excellent photographic reproductions, and one or two beautiful coloured pictures.

TRAINING BOY SCOUTS.

THE efficiency of the admirable organization that sprang from the fertile brain of Baden-Powell must of necessity depend upon the qualities of the scoutmasters, those grown-ups who supervise the activities of the boys and are to them outward and visible standards of what they wish to be in youth and later years. So far the movement has largely depended for the quality of its scoutmasters upon the training these have received at public schools and universities; and it would appear that there has been little or no disappointment in the quality that has been obtained. But since the work that they have to do is in reality a highly special type of educational work, it is logical that there should be provided for them some instruction in the basis of modern educational methods as formulated in recent psychology. Dr. F. W. W. GRIFFIN has done this for the scoutmaster in a little book entitled *The Quest of the Boy*.[5] In it he takes his readers through the whole scheme of psychological training. Beginning with the special senses, and the bearing of these on games and tests, he proceeds, through the consideration of association and mental concentration, to the unconscious self. For the explanation of this conception he gives a rough diagram of a steam lorry, in which the several parts suggest organs of the body, its instinct and its consciousness. Then these instincts are dealt with severally and very faithfully; so also the emotions; and, finally, there are chapters on conscience and conduct and the dawn of manhood.

It is no easy matter to write a book of this sort. It might have been so psychological as to be unintelligible to the ordinary reader. It might have been so "plain spoken" in the matter of certain theories as to be nauseating, and the last book that should be put into the hands of scoutmasters, who are very human. And yet it is a book that needed writing. The psychology of behaviour is too well known and too important to be overlooked in this regard, and it is well that it has been dealt with by one who is a doctor, one with knowledge of men and emotions, one who is in keen sympathy with the boys' movement, and one who takes a high standard. In the introduction we read: "A man who is called to serve the boyhood of his generation must . . . fire his life with the Good, the Beautiful, and the True, so that another may catch the torch from him, and illumine a little more brilliantly the darkness of this troubled world. . . . He must charm to harmlessness the wild beasts of ignoble earthly lusts; he must be a trumpet call to noble thoughts and deeds. . . ." Dr. Griffin has done his work well.

X-RAY DIAGNOSIS.

IN a book entitled *X-Ray Diagnosis*[6] Mr. J. MAGNUS REDDING endeavours to accomplish what others have attempted before—namely, a survey within a short space of all the varying conditions in which a radiographic examination may be of diagnostic assistance. He has succeeded as others have succeeded, and failed where others have failed, for the ground to be covered is so vast that in no textbook of this size is it possible to succeed beyond a certain fairly well defined point. A number of conditions are adequately considered and illustrated; the vast number can be only casually mentioned.

In his preface the author states that he hopes that the book may be useful to post-graduates preparing for the diplomas in radiology. It is to be feared, however, that this kind of book, attempting so much, fails in this respect; it may be of use to the general practitioner and to students, but cannot be considered adequate as a textbook for special examinations. A further criticism may be made as regards the illustrations: in many the great reduction in size from the original negatives means that essential detail is lost; in addition to this, very many show still more loss of detail and quality owing to imperfect reproduction. Recognizing these limitations, however, there is much to be praised in the general arrangement and in the manner of presentation of the subjects. The author has very wisely left out technique and the usual lengthy and useless descriptions of apparatus. A short introductory chapter is followed by one on the normal appearance of bones and joints; this includes ossification and developmental abnormalities. Four chapters on abnormalities of bones and joints follow. To the thorax five chapters are allotted, and to the alimentary tract three. Other conditions each with its own chapter are the accessory nasal sinuses, the central nervous system, the genito-urinary system, and the biliary tract, and the book concludes with an index.

Generally each condition dealt with is given a paragraph of greater or shorter length, the condition described being indicated at the commencement of such a paragraph by larger lettering, which makes it very easy to find the exact thing desired.

THE MEANING OF DISEASE.

DR. WILLIAM A. WHITE, the psychiatrist and neurologist, has written a book on *The Meaning of Disease*.[7] It is described as an inquiry in the field of medical philosophy, and is on the same lines as some of the writings of Dr. F. G. Crookshank, to whom reference is made. Dr. White maintains that as a result of specialism, and the analytical rather than the synthetic method of thought engendered thereby, there is not any adequate theory of disease at the present time; he therefore proceeds to examine some fundamental principles with the object of solving by the synthetic method many problems which have long resisted the analytical method. Health and disease are regarded as relative terms, and as health, like disease, is not a unitary but a relative concept, we may come to speak of healths as of diseases. He follows the late Sir Clifford Allbutt in pointing out that disease is not a fixed morbid entity, but the reaction of the individual to a *noxa*; he defines disease as a failure, more or less complete, in adaptation to external or internal circumstances, and describes the symptoms as the evidence of this contest, and, to a large extent at least, directly or indirectly signs of the way in which the organism is resisting destruction and combating death. He considers that the interpretation of the language of the patient is an important way of gaining knowledge of his unconscious motives, and discusses the difference between functional disorder and organic disease: when function which has not been "structuralized" becomes disordered there is functional disease, and, since this disordered process is reversible, recovery is possible, but the treatment should be, though it often is not, carried out by approach to the psyche. When function has been structuralized and becomes disordered there is gross organic disease, and, as organic lesions are in Dr. White's view irreversible, any recovery is due to a process of readjustment and compensation on the part of the remaining organs or tissues.

This work, with many illustrations from other works on psychology and philosophy, deals with an aspect of medicine which, though difficult, is of interest and of educational value.

NOTES ON BOOKS.

IN *Food Values and Recipes for Diabetics*[8] Drs. S. MILLER and F. B. SMITH have compiled a series of tables to assist diabetic patients to maintain accurate control of their diet. The carbohydrate, protein, and fat proportions of various foods and drinks are stated, and suggestions are given for combining the different ingredients in a meal, and for preparing composite dishes.

The second edition of Dr. LEONHARD JORES'S book on the application of anatomical principles to various important diseases[9] is almost double the size of the first, which was published in 1912 and has been out of print for nearly six years. The book consists of an introduction and twelve sections, dealing respectively with disturbances of nutrition and metabolism, endocrinal changes, local circulatory disorders, inflammatory and infectious diseases, diseases due to animal parasites, post-infective conditions and intoxications, the action of foreign bodies, regeneration and healing of wounds, alteration in the form and position of organs, blood vascular disease, tumours, and malformations. An appendix is devoted to chondrodystrophy, osteogenesis imperfecta, and extrauterine pregnancy. The text is accompanied by numerous excellent illustrations, many of them in colour.

The increase in the numbers of the medical profession is again reflected in the *Medical Register*[10] for 1927, which contains 52,614 names as compared with the corrected figure of 51,738 for the previous year, and with 50,035 for 1925. During the past year 2,120 names were added; in 1925 the additions numbered 2,570; and in 1924 (which marked the summit of the exceptional post-war period) there were 2,796 new entries, almost exactly twice the figure for 1914. Of the new names in the present issue 1,059 were registered in England, 527 in Scotland, and 361 in Ireland; 165 were colonial, and 8 foreign. The number removed from the *Register* was 1,159, as compared with 947 and 978 in the two previous years. Of these 1,159 names 828 were removed on evidence of death; 328 were removed because of failure to reply to the inquiries of the Registrar as to cessation of practice or change of address; and 3 were struck off under the disciplinary powers conferred on the General Medical Council by the Medical Act of 1858. As the interest of these official volumes is, for our present purpose, mainly numerical, one further figure may be quoted: the total number of persons registered from the beginning of medical registration in 1858 up to January 1st, 1927, was 100,430.

The *Dentists Register*[11] for 1927, which corresponds in form and arrangement, though not in bulk, with the *Medical Register*, contains 14,395 names, being an increase of 196 over the figure for the previous year. The entries are grouped under the headings "United Kingdom Dentists," "Colonial Dentists," and "Foreign Dentists." A useful feature of the volume is the local list of names appearing in the *Dentists Register*, arranged under the several postal sub-districts of London and under the towns, respectively, of England, Wales and Monmouthshire, the Channel Islands, Isle of Man, Scotland, Northern Ireland, Irish Free State; Europe, Asia, Africa, America, and Australasia; and the Services. During the year under review 380 dentists were registered with qualifications, and 43 under the provisions of the Dentists Act of 1921. Of the total names in the present edition 6,649 (45 per cent.) are registered with medical, surgical, and dental qualifications, and 7,926 (55 per cent.) are registered under the provisions of the Dentists Acts of 1878 and 1921.

The General Medical Council has also issued a volume[12] containing the lists of medical and dental students registered in 1926. Each entry indicates the preliminary examination in arts and pre-registration examination in elementary science passed by the student, the date of registration, and the date and place of commencement of professional study. The medical students registered last year were 1,260, as compared with 1,070 in the previous year; these figures contrast sharply with the unprecedented total—3,420—in 1919. England again heads the list with 577, though on four occasions in the past ten years Scotland has had the largest entries. Registrations of dental students numbered 229, as compared with 191 in 1925.

Mr. LUDOVICI tells us in his book *Man: An Indictment*[13] that the modern Englishman suffers from overmuch humour, and that this is one of the signs of his degeneracy. Perhaps the attitude of the author towards humour accounts for the boredom we experienced in trying to read his book. Mr. Ludovici has an idea which, with a little more humour and at considerably less length, might have been expounded in an interesting manner. He thinks that modern man, especially the Englishman, is degenerating, and he finds a sign of this degeneracy in the claim for greater power made by women. He marshals an array of arguments to show that the feminists have no right to suggest that the mental capacity of women has increased. For him the apparent dominance of women is to be attributed to the degeneracy of man. We are led through lengthy tirades against the Christian religion, especially puritanism, against the Englishman's shamefacedness about the act of procreation, against miscegenation, and against the neglect of breast feeding. We are advised to consider the eugenic possibilities of in-breeding, and even of incest, and are recommended to study the art of correcting faulty co-ordination of our bodies. Throughout it all we seem to trace the influence of the author of the *Will to Power*. We feel sure that Nietzsche would gladly have lent a hand to help his stumbling disciple on his way.

The British Journal Photographic Almanac[14] for 1927 includes a pictorial supplement, with reproductions of notable photographs taken during the previous year. It is stated that photographs, whether previously exhibited or not, will be welcomed from all countries. The editor, Mr. GEORGE E. BROWN, contributes some practical notes on the use of the reflex camera, with illustrations showing the advantages of this type of camera for various subjects. Mr. T. L. J. Bentley describes the preparation and arrangement of snapshot photographs, with suggestions as to trimming, mounting, and framing. Other articles deal with developing and printing from the standpoint of the dispensing chemist, and the use of chlorobrom papers. The book contains the useful features of previous issues, including an epitome of progress, various tables and formulae, miscellaneous information, and a directory of photographic societies; it will certainly be as popular as its predecessors.

PREPARATIONS AND APPLIANCES.

Electric Light Fittings.

THE development of the high efficiency electric glow lamps during recent years has opened up special problems in the use and fitting of these lamps. There is no question of their economy. For a given current their light is greatly superior to any other previous type of electric light. But the intrinsic brilliancy of the lamp—that is, the intensity of the light at its source—renders them dangerous unless they be properly fitted so that the filament is not seen naked by the eye. Exposure to the naked filament seriously interferes with comfort, and actually the visual performance of the eyes is reduced so that the benefit of the new lamp is lost. The lamp must be either so high that it is out of the line of sight, or it must be surrounded with a glass bowl or similar device which, by greatly diffusing the luminous area, diminishes its brightness to a comfortable value. The bowel then becomes the effective source of light, and its large size renders the shadows softer than those given by the bare source. The production of opal bowls for this purpose has been greatly stimulated, and recently the Illumination Research Committee of the Department of Scientific and Industrial Research[1] has investigated and reported on the effect of these fittings, measuring by appropriate means the surface brightness of the bowls. The work was carried out at the National Physical Laboratory. Eighteen different patterns were tested. They are reported to come out well from the tests, since the glass is uniform so that the light is smoothly diffused. There are two main patterns. A bowl, like a pudding basin, suspended by the rim, the lamp being hung within the bowl; in this way the light is reflected upwards to the ceiling, and passes through the opal glass of the bowl. The tests only concern the light that passes through the bowl. The second class of fitting is an enclosing globe, round or squat as may be. The light from this source is mainly that which is directly transmitted through the

[1] *Surface Brightness of Diffusing Glassware for Illumination.* By O. J. W. Grieveson, M.A., B.Sc. London: H.M. Stationery Office, Kingsway, W.C.2. 1926. Price 9d. net.

glass, but there is also internal reflection downwards from the upper covering of glass, and there is a sufficient illumination of the ceiling. The advantage of the closed globe over the open bowl lies in the fact that the globe does not lose efficiency when dust collects upon the upper surface; whereas the bowl, unless frequently cleaned, becomes a dust accumulator. Neither of these points, however, comes into the matter of this test. The conclusion is that the samples submitted for the most part did secure an even and therefore comfortable diffusion of the light. With equal lamp power it would appear from the figures that the closed globe gave a higher surface brilliance possibly because the completeness of the globe allows a thinner glass to be used.

Models of the Labyrinth.

Mr. A. H. CHEATLE, C.B.E., F.R.C.S., and Mr. V. E. NEGUS, M.S., F.R.C.S., have made models for the purposes of investigating labyrinthine diseases and for teaching students. They are double natural size and are made of Wood's fusible metal, which is sufficiently strong for ordinary purposes; the ampullary ends are painted in different colours in order to show them up; it is easy to make reproductions of the semicircular canals and cochlea from one petrous bone, and it is also easy to make models of the labyrinth if accuracy is not desired. But the intention has been to produce a model which would be properly orientated. As previously described (*Proceedings* of the Royal Society of Medicine), the method used was to fix a hollow tube between the internal auditory meati of a dry skull, and to hold this hollow tube in place by means of a rigid frame, which had bars clamped on to the side of the skull in such a way that the lower edge of each bar coincided with the Frankfort plane; that is to say, the upper margin of the bony external auditory meatus and the lowest point of the orbit. Metal was run through the foramen ovale of one side to fill the cochlea and semicircular canals of that side and to pass across the hollow tube to the opposite labyrinth, which was also filled, the hollow tube being rigidly held in place by cement. The next step was to remove the bone and to extract the complete model in one piece. The casting presented considerable technical difficulties, which were overcome by Mr. Shaw, who managed to produce an intact model at the Royal Dental Hospital. Enlargements were then made to double size, not by a modelling machine, as had been hoped, but by free-hand work. The models were made in silver by Mr. Thomas, seal engraver and medallist, who exercised extreme care in getting details accurate and the orientation of the canals perfect. Having secured the enlarged model, it was then necessary to arrange for reproduction in mass. This again caused considerable delay, as it was difficult to find anyone who could undertake the work. Success has been attained, however, by Messrs. Gerrard, furriers and naturalists, who made piece moulds and cast the two labyrinths together in Wood's metal. The original frame was made by Messrs. Mayer and Phelps, and they have made head frames with a pointer to lie parallel with the Frankfort plane in such a way that when the frame is on the head the labyrinth lies in correct orientation in all respects. The patient's head can then be put into any position and the exact relations of each of the canals are seen; rotation and caloric tests can be carried out with the frame in position. It must be remembered that there may be slight variations in the inclinations of the canals in individual skulls. The whole apparatus of enlarged models and head frame, "King's College Hospital" pattern, can be obtained from Messrs. Mayer and Phelps, 59, New Cavendish Street, W.1.

SCIATICA: ITS CAUSE AND TREATMENT.

LECTURE BY PROFESSOR PUTTI.

LAST week Professor VITTORIO PUTTI, director of the Istituto Ortopedico Rizzoli, Bologna, delivered the Lady Jones Memorial Lecture in the University of Liverpool. A large and appreciative audience listened for an hour and a half to an address in fluent English on "New conceptions in the pathogenesis and treatment of sciatica."

After discussing the history of the complaint, Professor Putti passed on to a survey of its prevalence in all classes and its importance as a clinical entity. It was, he said, always a syndrome secondary to some other pathological condition, and after giving the classification he preferred—namely, peripheral and central—he went on to say that his remarks would be confined to what had hitherto been regarded as primary or idiopathic sciatica. He dealt with the recognized signs and symptoms, laying stress on the position adopted by the patient, the loss of ankle-jerks, and Lasègue's sign. This type of sciatica commonly occurred after some slight chill or similar exposure, a point which had some bearing on his conception of the etiology. Professor Putti then briefly described the anatomical relations of the nerves entering into the composition of the great sciatic, emphasizing the large part played by the fourth and fifth lumbar roots. Mention was made of sacralization of the fifth lumbar vertebrae and the part played by this condition in simulating sciatica. Some excellent radiographs were shown of unilateral and bilateral variation. He demonstrated the path traversed by the lumbo-sacral plexus and recalled the work of Sicard in dividing the fibres into the following sections: before leaving the canal, between the canal and the plexus, in the plexus, and after the plexus.

"Neurodocitis."

He then laid stress on that part of the nerve in the intervertebral foramen, and said that he wished to coin a word, "neurodokon," for this part—a word which he applied to any nerve contained in an osseous or fibro-osseous canal, calling inflammation of this part "neurodocitis." By means of instructive diagrams he showed that the relative sizes of the five lumbar intervertebral foramina decreased from above downwards, while their length and the size of their contents increased. He recalled the boundaries of the intervertebral foramina, drawing particular attention to the proximity of the articular processes and facets. By means of a further diagram the arrangement of blood vessels in a plexus around the foramina was well demonstrated, and diagrams taken from actual *x*-ray photographs showed that variations in the plane of the articular facets (from the sagittal to the coronal) would materially affect the "neurodokon." An arthritis of the intervertebral articulations, on account of small osteophytes, oedema of the soft tissues, or congestion of the plexus referred to, would cause pressure on the nerve and consequent pain.

Diagnosis.

Any arthritis calls forth in response a reflex spasm of the surrounding muscles which is protective in nature. This should always be looked for in cases of sciatica, and in some cases was so marked as to give rise to a scoliosis which had been called by various authors "sciatic scoliosis." This might be homolateral, contralateral, or alternating, the explanation being that in the homolateral cases spasm of the muscles of the same side drew the body over, in the contralateral cases muscles of the opposite side contracted to relieve (by opening out) the intervertebral foramina, and that in the alternating cases the arthritic condition was bilateral and the relief of the "neurodokal" pressure was obtained by muscle spasm, first on one side and then on the other. The presence of the arthritis was shown by haziness of the articular surfaces, by increased density of the neighbouring bones, or even by osteophytic outgrowths. Narrowing of the intervertebral foramen could be ascertained by radiography, but for this purpose good prints and stereoscopic views were absolutely essential.

Treatment.

After briefly surveying the methods in general use for the relief of sciatica, Professor Putti indicated the lines along which he worked. These consisted of rest, preferably by immobilization in plaster-of-Paris jackets, followed by active hyperaemia. The jacket must be well made, moulded to fit perfectly, and could at first be worn only for a short period such as thirty minutes, for the patients were intolerant of fixation in one position for any length of time. The splint was usually tolerated for a gradually increasing space of time and eventually worn continuously. At the end of three to six months active hyperaemia of the parts was induced by means of radiant heat, the jacket being reapplied after each session. The whole time of treatment was usually from nine to twelve months. In exceptional cases this proved unsuccessful, and recourse was had to operation, which consisted in the removal of the posterior wall of the intervertebral foramina, usually necessitating the cutting away of laminae and articular processes. One case in particular was recorded. Excellent radiographs before and after operation were shown, and an entirely successful result six months after operation was reported.

Conclusions.

Professor Putti summarized his points as follows:

1. The importance of "neurodocitis."
2. Its recognition by good stereoscopic radiographs.
3. Its treatment by rest and active hyperaemia and occasionally by radical measures.

Nova et Vetera.

MATTHEW BAILLIE'S DIARY OF TRAVEL IN 1788.

A CONTEMPORARY of Arthur Young and John Howard, a successor of Tobias Smollett, and a predecessor of the Dutch Tilanus, Dr. Matthew Baillie went on the grand tour in the spring and summer of 1788. The record of the journey through France, Switzerland, Germany, Flanders, and Holland is contained in a modest diary, and is chiefly a survey of hospitals and anatomical museums and collections. The little volume, resembling a pocket-book, in which the traveller recorded his impressions was handed down in the family of his descendants and had remained unnoticed till it came into the Library of the Royal College of Surgeons in the summer of 1926. That its contents were unknown is hardly to be wondered at, for it is written partly in faded ink and doubtless with the worn quill pens found in primitive foreign inns of the year 1788. Moreover, it is couched in a queer attempt at French, which begins bravely when Baillie leaves Paris to travel eastward, and ends rather lamely as boredom and fatigue assail the traveller. The little MS. was unknown to Matthew Baillie's biographers, James Wardrop and Sir Norman Moore, and was evidently so lightly regarded by the writer himself that he makes no mention of it in his MS. biography, "A Short Memoir of My Life with a view of Furnishing Authentic Materials." Yet he there refers to his travels and says:

"In the course of this short sketch of my life I forgot to mention that in the summer of 1788 I made a short Tour on the Continent, in which I pass'd through part of France, of Switzerland, of Germany, of Flanders and of Holland. Many scenes with which I was delighted in that Tour are still strongly impress'd upon my mind."

Baillie was aged 27 in 1788 and was already well known as a lecturer on anatomy in the Windmill Street school, the use of which for thirty years had been left him by his uncle William Hunter. He published his first paper in the *Philosophical Transactions* in that year, and in 1789 became F.R.S. William Hunter had left him £5,000, and the estate of Long Calderwood, which latter he had of late generously handed over to his famous surviving uncle, John Hunter. He was therefore not too rich, and he gives one the impression in his descriptions of travel of being still a modest beginner, economical, alert, and eager to make the most of his opportunities. Yet he was fully imbued with the Hunterian tradition as to the collecting and preservation of anatomical specimens; he had served also under private teachers and amid private collections. Accordingly he found the carelessly preserved State collections of the Continent, under dilatory conservators, inflated with the kind of academic pomposity then common abroad, in many instances highly unsatisfactory. The hospitals, too, struck him as ill managed—overcrowded and often not too clean. On May 8th, in Paris, he records:

"We went to see the Hôtel Dieu, were through every ward, saw the large vessels for washing the Linnen, saw the Butcher's Shop for supplying the Hospital, the stable for the Cattle, the Kitchen, etc. 1800 lb. of meat consumed there every day in summer, 2000 consumed in Winter. A Row of beds at each wall. 2 rows of bed contiguous to each other in the middle. Now in it above 3000 patients."

Next day he visited the Hôpital St. Louis, an appendage to the Hôtel-Dieu,

"intended for patients having the itch, eruptions, and incurable complaints. Wards high—two, three, and sometimes 4 patients in a bed. Contains above 600 patients."

He had a far higher opinion of La Charité hospital,

"the best by much in Paris—218 Patients in the house—men only —one patient in one bed. Beds at very considerable distance from each other—Roofs rather low—Attended by Monks and Nuns and therefore probably well attended—A commodité between every two beds—Some good pictures in the Wards."

At Bicêtre he noted 250 madmen, and that some of the worst prisoners were sometimes kept in a "dark dungeon." He visited the Ecole Vétérinaire outside Paris and was dissatisfied with the museum.

"Saw some very good diseases of bones and calculi. The coarse injections were pretty good—well varnished—but the muscles most commonly removed so as to give no idea of relative situation. Some few tolerable absorbent preparations of the intestines, spleen, etc. Some preparations of Horses, Bulls, etc., with muscles preserved but not well managed. Some preparations of fetuses with their membranes, monsters, but not well suspended in the bottles—some fish—some stuffed Birds and beasts. Two Halls for preparations—Saw the stables with the Horses under cure. The chief means they employed were Setons and Purges. Saw a Room for dissection, large and airy, but nothing in it at present. Saw the shop for the medicines, etc."

At the Salpêtrière he saw the "*folles.*"

"They were chained to the wall and are expos'd to every sort of weather day and night. When they are not very much affected in their Intellects they are allowed a Bed and are protected from the weather."

On the other hand, the hospital of the *Petits Enfans Trouvés* struck the traveller as "very clean and neat." Above twenty foundlings were "laid at the door each night." Illegitimacy was rampant in Paris during the piping times of the Ancien Régime, and it is a question whether the modern "apache" is not a descendant from the irregular sex relations of that as well as a later epoch. The foundlings observed by Matthew Baillie were under a severe rule. "They rise at half-past 4, breakfast at 6, dine at ten and sup at 5 in the evening, after which they soon go to sleep." Four large hospitals, says our author, are proposed at Paris, and these doubtless were in time built and became the famous institutions where, in the Napoleonic epoch and later, the great surgeons Dupuytren, Larrey, Boyer, Dumeril, and their colleagues performed the operations which were the admiration of Tilanus and his fellow travellers.

Baillie travelled to Lyons in June, passing through a country traversed at much the same time by Arthur Young, who on this his second journey rode his mare 3,700 miles. Young brought back chicory seed from Lyons, and made many of the agricultural and sociological observations by which he is remembered. Baillie also thought it his duty to note crops wherever he went, and in France and across the Rhine records his observation of wheat, hemp, vines, tobacco, potatoes, and scattered trees in an unenclosed country, which puzzled him. In Lyons he visited the Hôtel-Dieu, a superb hospital with its 1,100 iron bedsteads. Each patient had a bed to himself, but there was a lack of visiting physicians and surgeons. A year later John Howard says of this hospital:

"The summer white furniture of the beds was changed into a dirty blue harradeen [a coarse woollen cloth] with useless fringes, well fitted to retain infection. The rooms were nasty and offensive; and two patients in many of the beds, but not one window open; the medical gentlemen here, and also the charitable sisters, being prejudiced against a free circulation of air, as well as against keeping rooms clean by washing them." (*An Account of the Principal Lazarettos in Europe*, etc., 4to, Warrington, 1789.)

Baillie next visits Geneva, passing through scenery which strikes him as being as romantic as that of the Hebrides. His travelling companion, a Dutchman, is the most disagreeable he has ever met, and his driver, an Italian, moves at a foot's pace. He says nothing, however, of the people in the inns, who struck Smollett as so surly towards travellers. Nor, indeed, does he comment, as does Arthur Young, on the eve of the French Revolution, upon the apparent prosperity of the peasants. The Geneva Hospital calls for little notice, but at Lausanne he is struck by the infirmary, which differs, he says, from all those so far visited by him. There are never more than four beds in one room: the insane are in rooms, and there is a department for the care of veuereal patients. At Chamounix he notices two albinos, children of brunette parents. They are a surprise to him, as he does not appear to be familiar with the German writings on the subject of albinism published from 1777 onwards. At Berne he admires the clean orphanage and the fine workhouse. At the hospital he finds eight wooden bedsteads in each room, and there is no apothecary's shop in the house as in most foreign institutions of the kind. Prisoners are well cared for at Berne, which as a whole impresses the traveller by its cleanliness and general culture. At Strasbourg later on he is back on French soil, and here he has much to say, his account comparing interestingly with that of Tilanus. At the school of anatomy he finds a museum with 400 preparations, which include some monsters, snakes, and lizards. The specimens strike him as dirty and ill hung. He mentions the double matrix afterwards seen by Tilanus and commented upon by Eisenmann as early as 1752. Tilanus gives a curious account of what was still a

primitive kind of museum in the early nineteenth century. "The specimens are not placed in show cases," he writes, "but stand on unpainted wooden shelves, and some of the large ones lie loose on the floor." A railing presumably keeps visitors away from this derelict collection. Baillie approves of the orphanage, but finds it overcrowded with beds, of which there are six or seven rows in each ward. The Foundlings' Hospital is similarly overfull. In the huge military hospital he finds 350 patients in two or three rows of beds and in large wards. The latter are dirty, but hot and cold baths are provided, and there is a good laundry with good linen. The town hospital is dirty and overcrowded; he finds as many as seven rows of beds in one room. The beds are of wood and curtainless, and the absence of curtains seems always to distress him. There are three physicians and two surgeons, who are followed by pupils. There is a small madhouse with eighteen beds and a bathroom; this he condemns as very badly arranged and dirty. He is, of course, comparing things as he finds them with John Hunter's museum and arrangements at home and with St. George's.

Tilanus finds that these institutions have expanded in his day. Of the anatomical specimens, which in 1819 are separated from the natural history, he says: "The arrangement and the classifications are much better than at the Ecole de Médecine in Paris." But, like Baillie, he finds the hospitals overcrowded. He, however, praises the University Clinic, which has since the armistice of 1918 grown into one of the largest and finest hospitals in Europe. He differs from Baillie in mentioning several professors, such as Berot and Lobstein, the teachers of Goethe.

In the museum of the school of anatomy at Mannheim the diarist notes that of the 300 preparations many are ill sealed in their bottles. The professor has not the art of sealing, so well practised in the Hunterian museums. On later occasions he makes a like observation. He has little to say of the two hospitals, but notes that soldiers who die there are given to the professor for dissection, etc. At Frankfurt-on-Main he visits a very clean hospital, and another devoted to strangers, which is dirty, crowded, ill built, and devoid of baths and operating theatre. The clean hospital is doubtless the famous Senckenburg Institute, founded by a medical man, and fully described by Tilanus as one of the glories of the town. The diarist fails to examine a medical library which he finds in Frankfurt. At Mayence the Hospital of the Poor is full of patients, paupers, and orphans. The wards are rather dirty, bed linen and napery fine and very clean. The hospital, like others in Germany, is under a superintendent. Baths are lacking. Baillie has little to say of the Brussels and Antwerp hospitals, except that the medicines there are made up by the religious and the wards are a little crowded. In Holland he is loud in praise of the general cleanliness. At Rotterdam he notes the anatomy collection belonging to the Surgical Society. The 500 specimens strike him as being badly suspended and sealed, but the *eau-de-vie* in which they are preserved is clear. The petrified skeleton of a child arrests attention. The hospital is very clean, but there are often two in a bed and the rooms are too small. There are only about 30 patients out of a possible 200. There is a superintendent, and a physician and two surgeons pay daily visits. The Hague delights him as the prettiest town he has ever seen. He finds the anatomical museum at Leyden badly arranged and the jars ill sealed. The cabinet of Albinus contains superb injections, of which there are some 200. In Paris he had already viewed M. Sue's collection of anatomy, where he found "some good coarse injections," but "not a preparation in a bottle in the whole," and other collections, notably that of Madame Binns. The last-named consisted of some sixty specimens in wax modelled by this remarkable woman, who had studied anatomy secretly from her childhood onwards. The King of France bought her collection, and our diarist found many errors in the anatomy.

The trip ended in Amsterdam, where he had not time to view the hospital, but was loud in praise of the vast poorhouse, which is also a penitentiary.

That Matthew Baillie was a man of a sound classical education and considerable culture is well known. It is interesting to note the many but all too short observations on things in general contained in his diary, as these, taken together, afford a good idea of the mind of a cultivated medical man towards the close of the eighteenth century, when the so-called Age of Reason was merging in modern romanticism. In Paris, in May, 1788, nothing foreshadows the French Revolution of the following year. The Bastille is *in statu quo*—"a dark gloomy building with 8 turrets, surrounded by a high wall." The Louvre contains paintings "in extremely bad condition," "many much decayed." "Some statues—these extremely mutilated. Nothing put in proper light to be shown to advantage." On the other hand, the collection of minerals in the "Hôtel des Monnoies" is superb and the lecture room most elegant. The King's library, with its 300,000 volumes, is in excellent order, so also is the botanic garden. At the chapel of the English Benedictines, in "a corner set apart," he views the sepulchre of James II and the death mask in wax "taken as soon as he was dead." The Jacobins afterwards desecrated this Jacobite shrine and drew the King's fine white teeth. A visit is paid to Mr. David, "the first painter in France," and frescoes by Mignard are admired. The Palace of the Prince de Condé is the most superb he has ever seen. At St. Cloud "I saw the Count d'Artois playing at cards with some noblemen." At Versailles he sees the Cordon Bleu procession—

> "Nobles with black Cloak and Gold with blue sash all in chapel at 12 o'clock. King there—Queen in Gallery above—High Mass perform'd—Queen and King din'd afterwards [in public]—Gold Plates, etc."

The gardens of Versailles he finds very beautiful with their many "jetteaus" and orange trees. In the menagerie the "hyaina" and rhinoceros are the most remarkable wild beasts, and the buildings are extremely good. At the Jardin du Roi he is tickled at seeing a statue of Buffon "at the turn of the stair" in the Cabinet of Natural History with "animals, fossils, etc., lying at his feet," and the proud motto "Majestati Naturae par ingenium." This statue must have been known to Buffon twenty years before his death. He attends a meeting of the Académie des Sciences, and hears an abbé read a paper on the strata of the Pyrenees, illustrated by a piece of rock. A learned member called it "schorl, which rather abash'd the Abbé."

Outside Paris the traveller views everything somewhat from the eighteenth century point of view. He has little eye for scenery, though he commends the glaciers at Chamounix and "the shepherdesses." On the Rhine also he admires the customary views near Coblentz. Gothic architecture is admired as such, but he prefers "neat, elegant" classical buildings. However, he admits that Strasbourg Cathedral is the most superb ever seen by him. In Flanders and Holland he mentions very few painters save Rubens. At the Hague and Haarlem Franz Hals and Vermeer, and also the "Anatomy Lesson" of Rembrandt, seem as yet unknown, for he makes no mention of them. Among picture galleries he gives the palm to the collection of the Elector at Mannheim, though the Palais Royale in Paris ranks high in his estimation.

V. G. P.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Committee thirty-eight cases were considered, and £746 10s. voted to thirty-six applicants. The following is a summary of some of the cases relieved.

L.R.C.P. and S., aged 63, has, through illness, been unable to act as locumtenent and is now in hospital. To meet his expenses an emergency grant of £5 was sent, and a further sum of £40 voted.

M.R.C.S.Eng., aged 57, worked as an assistant until December last, when he was taken ill and is now in a nursing home. Only assets £120 capital and about £50 worth of furniture. The Fund sent 10 guineas and voted a further £40 payable in six instalments.

Widow, aged 67, of M.R.C.S.Eng. who died in 1914. Through failure of investments and the loss of a son who contributed to her support, she has taken a post as housekeeper at £60 a year. During the last two years she has broken her arm, and twice broken her ankle. She has £62 from two pensions, but debts of £20. She was voted £10.

Daughter, aged 40, of M.B.Aberd. who died in 1905. Supported herself as a clerk until 1925, when she had a serious breakdown, and is entirely dependent on her sister, who is a bank clerk. £10 was voted.

Daughter, aged 60, of M.R.C.S.Eng. who died in 1913. Owing to her age she has great difficulty in finding employment as a dispenser, and last year only made £82. From investments she received £24. Board and lodging cost her £80. She was voted £12 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, London, W.1.

THE SCHOOL OF PATHOLOGY AT OXFORD.

OPENING OF THE SIR WILLIAM DUNN LABORATORIES.

WHEN Convocation resolved to set aside nine acres of the University Parks for the extension of the science departments of the University, nearly a third of the site was allotted to the School of Pathology. Upon this piece of land, bordering the north side of South Parks Road and within 200 yards of the Natural Science Museum, the new pathological block has arisen in leisurely fashion during the past three years. Its position is shown in the sketch map on the next page. The money for building and equipment has been provided by the directors of the Commercial Union Assurance Company, acting in their capacity as trustees for the late Sir William Dunn, who, with far-sighted wisdom, left the bulk of his large estate to be applied to benevolent purposes in such manner as they deemed fit. The trustees, after full consideration by a small committee, decided to allocate two sums—one for the establishment of a biochemical institute in the University of Cambridge, and another for a pathological institute in the University of Oxford.

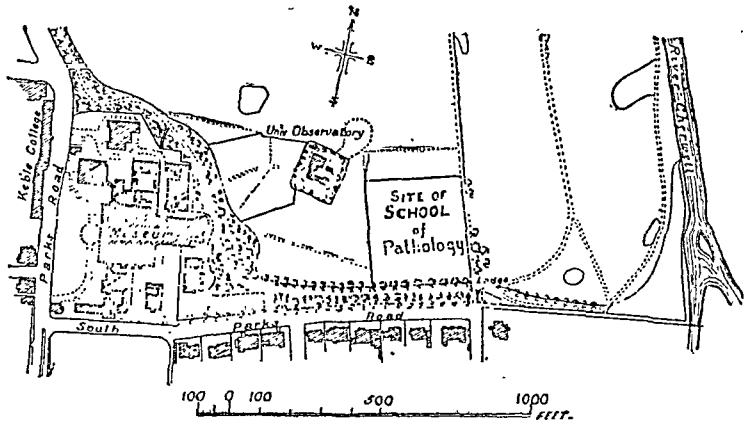
The New Building.

The Sir William Dunn School of Pathology at Oxford, which with its contents has cost not far short of £100,000, is under the direction of Professor Georges Dreyer, M.D., F.R.S., who has held the chair of pathology in the University since 1907. The architect is Mr. Edward Warren, brother of the President of Magdalen, who has succeeded admirably in reconciling the claims of art and the workaday needs of medical science. His design has produced a handsome building of red brick faced with stone, simple and well proportioned outside and in.

The main block consists of three floors, each with a long corridor running east and west of the central flights of stairs to the expanded wings at the ends. All the rooms, and the staircases and upper corridors as well, are excellently lit, with pleasant views over the Parks from many of the windows. The west wing, with large classrooms and library and museum, is for teaching, and the east wing for research; the basement comprises workshops, cold-rooms, sterilizers, store-rooms, mechanical plant, and so forth, all fitted with the latest appliances, and a low-pressure chamber that has an interesting war record. An airy outbuilding of two stories at the back of the grounds, connected with the main block by a covered way, provides good housing for animals—and for the boiler. The general appearance of the main frontage and east wing can be judged from the illustration; a corner of the animal house is seen on the right.

The old Pathological Laboratory in the University Museum (which has lately been refitted, at the cost of the Dunn Trust, to house the Pharmacological Department) was inadequate in many respects. The new building gives ample accommodation for twice as many students and research workers, with every advantage and amenity that modern equipment can provide.

[Photograph by] MAIN ENTRANCE AND EAST WING. [James Soame, Oxford.



The Opening Ceremony.

The opening ceremony took place on the afternoon of Friday, March 11th, in the presence of a distinguished company. Owing to attacks of influenza the Chancellor of the University (Viscount Cave, Lord Chancellor of England) and the senior member of the Dunn Trustees (Sir Jeremiah Colman, Bt.) were unable to attend, and Mr. Charles D. Seligman formally handed over the building to the Vice-Chancellor, Dr. F. W. Pember, Warden of All Souls, who accepted it on behalf of the University. The visitors were received in the lecture theatre by Professor Dreyer. The Vice-Chancellor attended in state, and beside him on the dais were Mr. Seligman and his co-trustees, the Hon. A. H. Holland-Hibbert and Sir James Leigh-Wood. A large number of Heads of Houses and other senior members of the University attended, including Sir Archibald Garrod (Regius Professor of Medicine), Sir Charles Sherrington, Professors Arthur Thomson, J. A. Gunn, and R. A. Peters, Sir Frederick Keeble, Professor E. B. Poulton, Dr. William Collier, Mr. R. H. A. Whitelocke, Dr. A. G. Gibson, and Dr. E. W. Ainley Walker (Dean of the School of Medicine). Among the visitors to Oxford were Sir Humphry Rolleston (Regius Professor of Physic at Cambridge), Sir Frederick Andrewes, Sir Frederick Gowland Hopkins (Sir William Dunn Professor of Biochemistry at Cambridge), Sir Walter Fletcher (Secretary of the Medical Research Council), Professor C. J. Martin (director of the Lister Institute), Professor J. S. C. Douglas (Sheffield), and Dr. Andrew Balfour (director of the London School of Hygiene and Tropical Medicine). Professors Moellgaard (Copenhagen) and Holst (Oslo) represented the Scandinavian Universities, and continuity with three former Regius Professors of Medicine at Oxford—Acland, Burdon-Sanderson, and Osler—was made by the presence of Dr. T. D. Acland, Professor J. S. Haldane, and Lady Osler. A large proportion of the company were in academic dress, and doctors of the University wore scarlet.

MR. SELIGMAN, in formally presenting the building to the University, expressed the general regret at the absence of the Chancellor and of the senior trustee, who had entered so fully into the project from the beginning. He then briefly recalled the history of the Dunn bequest, noting the wide discretion given by the testator to his trustees, and acknowledging the guidance given them by Sir Walter Fletcher. In approaching their task the trustees felt strongly that it was far better in the interest of mankind to get at the root causes of disease than to attack it when manifest. Hence their allocation of part of the funds at their disposal for the purpose of medical research and teaching, and for that there could be no better place than one or other of the great seats of learning. Mr.

Seligman ended his interesting and well informed speech by remarking that just as Sir William Dunn's Trustees had endowed a school of biochemistry at Cambridge and a school of pathology at Oxford, so the Rockefeller Trustees, with a fine feeling for symmetry, had endowed a school of biochemistry at Oxford and a school of pathology at Cambridge.

The VICE-CHANCELLOR, in accepting the munificent gift of the Dunn Trustees, recorded the gratitude and admiration of the University of Oxford for their wise and prescient stewardship. Sir William Dunn, he liked to recall, was an alderman of the Ward of Cheap in the City of London, and his posthumous gifts brought to mind the splendid endowments of Tudor days and of the seventeenth century. The compassion and breadth of mind of the testator were shown by his direction that a large part of his estate should go towards the alleviation of human suffering. To ensure the legality of using some of this money for medical research and education, his Trustees had prudently sought the sanction of the Court of Chancery. The University, too, might take some credit for granting so fine a site for the new School. Dr. Pember then briefly outlined recent developments in the study of pathology and bacteriology at Oxford. The first large step was taken by Sir Henry Acland, and a great impetus was given by his successor, Sir John Burdon-Sanderson. This new building, admirably designed and equipped, would give to those who worked in it the best modern facilities for teaching and research. In conclusion, the Vice-Chancellor, speaking on behalf of all present, paid a warm tribute to Professor Dreyer, who, during the twenty years of his work in Oxford, with straitened accommodation and equipment, but unwearying in resource and ingenuity, had inspired everyone around him with his own cheerful enthusiasm.

SKETCH MAP SHOWING SITE OF THE SCHOOL OF PATHOLOGY, OXFORD.

After the ceremony visitors took tea in the large laboratory above the lecture theatre, and had an opportunity of inspecting the institute and its annexe. All were agreed that its establishment will prove a great gain to the Oxford Medical School as a centre of teaching and investigation.

PATENTED RESEARCH.

IN our last issue we referred in general terms to the practice of patenting research, the subject having been suggested by the Drs. Dick patent. It would appear from the patent specification lodged in this country that an application for a patent was made in the United States on November 28th, 1924. We understand that under the International Convention an applicant for a patent in one country has a period of priority so that he can make similar application for a patent in other countries which are parties to the Convention. An application was lodged in the United Kingdom on August 31st, 1925, but this may have been a provisional specification. The "complete specification" (No. 243675) was accepted here on December 31st, 1926. "Accepted," so we understand, means that the Patent Office accepts the complete specification as fulfilling the rules and constituting a prima facie claim. The specification is published in the *Patent Journal*, and if no opposition is lodged within two months the patent is granted. In this case the period expired on March 12th, and so far as we are aware no opposition has been lodged. The matter is one of considerable importance, and doubtless the specification, which has, we presume, been accepted by the Patent Office, will be studied by all who are engaged in serological work. We set out below in full the eight claims made in the complete specification. The patent is taken out in the names of Dr. George Dick and his wife, Dr. Gladys Dick. The specification, in the first place, describes their methods of preparing the scarlatinal toxin, of identifying the specific streptococcus, of applying the skin test, and of preparing the antitoxin; and, secondly, enumerates the claims made under the patent. The latter are as follows:

1. The process of isolating hemolytic streptococci specific to scarlet fever, growing them in a suitable medium, obtaining the sterile toxin therefrom, injecting an animal with the sterile toxin and obtaining an antitoxin specific to scarlet fever.

2. The process claimed in Claim 1, wherein the said antitoxin is contained in a serum which is obtained from the said animal.

3. The process for the identification and standardization of an antitoxin which consists in isolating hemolytic streptococci specific to scarlet fever, growing them in a suitable medium, obtaining the sterile toxin therefrom, injecting an animal with the sterile toxin, obtaining an antitoxin specific to scarlet fever, and injecting the antitoxin into or through the skin of a human being.

4. An antitoxin specific to scarlet fever when obtained from the blood of an animal which has been injected with sterile toxin specific to scarlet fever.

5. An antitoxin specific to scarlet fever when obtained by the process claimed in Claims 1 or 2.

6. The process of isolating hemolytic streptococci specific to scarlet fever, growing them in a suitable medium and obtaining a sterile toxin therefrom.

7. The process for the identification and standardization of a toxin which consists in isolating hemolytic streptococci specific to scarlet fever, growing them in a suitable medium, obtaining a sterile toxin therefrom and injecting the toxin into or through the skin of a human being.

8. A sterile toxin specific to scarlet fever when prepared by the process set forth in any of the preceding claims.

The essence of the patent seems to be in the method of discriminating the scarlatinal streptococcus from other streptococci. This is done by means of a skin test analogous to the Schick test in diphtheria. Claim 6 prohibits everyone from isolating scarlatinal streptococci by this means. The other claims rest on this one; the toxin, antitoxin, and serum mentioned in the specification refer to such as have been obtained by the streptococcus so identified. Taking the claims altogether they practically amount to this: that the streptococcus identified in this manner is neither to be isolated nor made use of in any way whatever; and further (Claims 4, 5, and 8), that toxin and antitoxin are to be obtainable from the patentees alone. The patent may conceivably remain a dead letter; it would not be the first time that such a thing has occurred. But, assuming that it will be acted on, it cannot be otherwise regarded than as a serious hindrance to research, and it will be interesting to hear from the Drs. Dick why they have adopted this particular line of policy. Serological research has always been free from trammels of all kinds, and its phenomenal fruitfulness has been partly due to that fact. The claim of the Drs. Dick rests on a whole series of unpatented discoveries in the past, and is merely a natural, and probably an inevitable, sequel to them. They are making a break in one of the traditions of the medical profession for reasons which, we confess, appear to us obscure.

British Medical Journal.

SATURDAY, MARCH 19TH, 1927.

INFLUENZA AND THE HEART.

THE history of every epidemic of influenza shows that it invariably leaves in its wake a trail of victims who for a longer or shorter period after the main illness has passed away fail to recover their normal powers in one direction or another. A low blood pressure, a subnormal temperature, an excessive lassitude, are part of a chain of symptoms that incapacitate the sufferer for weeks or months; as Sir William Gowers put it, they suffer from an inertia so intense that every action may require for its initiation an effort of will that is almost painful, and its accomplishment results in undue fatigue and (it may be) even in collapse. In the mind of many this "good-for-nothingness" is ascribed to some deficiency in the action of the heart; and in the more tragic cases of sudden death, which always attract special attention when an epidemic stalks the land, the blame is often laid at the door of the prevailing scourge; the parson dies in the pulpit, the cook falls dead in the kitchen, and some unknown effect of influenza on the heart is adduced as an explanation of an otherwise inexplicable event.

The cases of simple bradycardia, which are by no means uncommon, and the rarer cases of heart-block of varying severity, can be shown, as Cockayne[1] pointed out, to give the typical electro-cardiographic response due to involvement of the myocardium and conducting tissues; but these account for only a small proportion of those cases in which, from a variety of symptoms, suspicion falls upon the heart. Exact information as to what damage influenza actually does to the heart is difficult to obtain; a considerable number of pathological investigations have been made on the condition of the heart in patients dying in the acute stages, and the evidence is somewhat conflicting. Sir James Mackenzie,[2] writing after the 1918 epidemic, stated that *post-mortem* examination revealed the extensive damage done to the myocardium, and suggested that influenza might lay the beginnings of a myocarditis which would ultimately end in heart failure; but, curiously enough, he had to admit that in a very considerable clinical practice he had not seen this occur, and he gave it as his opinion that the post-influenzal debility so commonly seen was not cardiac in origin. Dr. T. H. G. Shore,[3] in a report to the Medical Research Council, published some observations made during an outbreak among the troops in 1918, and has confirmed them during the recent epidemic. He found that there very frequently is a widespread hyaline degeneration of both skeletal and cardiac muscle, and to this he attributes the low blood pressure which he suggests is one of the important and characteristic features of the disease. Lucke, Wright, and Kime[4] also found acute parenchymatous changes in the myocardium in a large proportion of cases in a series investigated in America, in 90 per cent. of which there was dilatation of the right side of the heart. On the other hand, most observers in Germany and others in this country appear to have detected no exceptional change in the heart; a few cases, indeed, in most series have shown some form of myocardial degeneration of various forms, but on the whole there has been nothing in this respect to mark out influenza from other acute infective conditions where—as in typhoid fever, for example—a hyaline degeneration of muscle is of no particular rarity. These discrepancies may perhaps be accounted for in part by the fact that muscle tissue is queer stuff in the peculiar changes it may undergo according to the manner of death and of fixation, and different interpretations may well be placed by different observers on the varying changes found, whether they be gross or microscopical. Moreover, it may well be that many a case which has been passed as normal from its gross appearance would have shown some histological change.

There is, however, a very considerable body of opinion which looks upon the general debility, the low blood pressure, and the subnormal temperature of the post-influenzal state as symptoms of a derangement of the vasomotor mechanism, and as in no way dependent on a primary cardiac defect. In this connexion it is interesting to recall the work of Stoerk and Epstein[5] in Vienna in 1919. These observers examined the arteries in a series of cases dying of acute influenza; they limited their study to patients between the ages of 13 and 23 dying between the eighth and fourteenth day of the disease, so as to avoid as far as possible the inclusion of vessels that might have been damaged by other factors. As a result they found widespread degeneration of the internal peripheral vessels, with destruction of the muscle of the media; elastic layer and necrosis of the muscle of the body irregularly, but it was especially noticeable in the coronary this degeneration was scattered about the body irregularly, but it was especially noticeable in the coronary arteries; they particularly stated, however, that the cardiac muscle itself was not affected. Although they did not suggest that these lesions were specific for influenza—indeed, they pointed out the general agreement of their findings with those of Wiesel in other acute infections—yet they thought from their experience that the changes were more constantly present in influenza, and suggested that they did provide a pathological basis for the clinical symptoms of circulatory failure.

Whatever the future may reveal as to the underlying pathology, it is pretty clear that low systolic blood pressure is a very definite phenomenon both in the acute and in the post-influenzal condition. This may be due in the main to a primary cardiac lesion, but it is possible that the toxin in influenza may also have some deleterious action on the suprarenal bodies. Several workers have made investigations on this point, and Cowie and Beaven,[6] although unable to demonstrate any definite histological damage to the suprarenals, thought they found distinct evidence of "hypofunction"; but the advantage that has been claimed for treatment with adrenaline and other similar methods has received no great measure of confirmation. Treatment by drugs directed especially towards the heart has by general agreement proved conspicuously unfruitful, but attention given to the blood pressure and care to insist upon rest until it has reached a normal level may well save many patients from a series of distressing symptoms, and some from disaster.

ALCOHOL AND LONGEVITY.

ALTHOUGH no problem—the problems of religious belief and practice not excepted—gives rise to more bitter controversy than that of the use of alcoholic beverages, the amount of ground common to the holders of even extreme opinions on either side is really large. No educated man in the one camp doubts that alcohol taken in large doses at frequent intervals is a dangerous poison; in the other, the sternest supporter of total and lifelong abstinence from every form of alcoholic beverage does not believe that the taking of minute quantities of the drug at long intervals works irreparable harm. Similarly, although precisians of both parties may split verbal hairs, nobody seriously contends that alcohol is a "food" in the common-sense way that bread is a food, or that it is a "stimulant" in the sense that tea is a stimulant. The real controversy is on another plane. A prohibitionist might easily concede that a moderate use of wine does in fact add to the joy of life of thousands of good citizens, and yet maintain that the price to be paid in terms of social evil is too heavy to be borne. An antiprohibitionist might contend that, although for every pleasure of alcohol there is an adequate substitute, yet any attempt to suppress a usage older than civilized man would inevitably create more evil than it averted. In truth there are perhaps among educated men of to-day none who would either prohibit the use of alcohol in all circumstances or would free its use of any restrictions. All admit the need of some restriction; it is a delicate question of degree and method. To the solution of this problem Dr. Raymond Pearl, in a recent essay on alcohol and longevity,[1] neither makes nor affects to make any contribution. He is concerned with two questions — namely, our objective knowledge of (1) the racial or hereditary effect of alcohol, and (2) the effect of alcohol upon the average duration of life of individuals. His chief new contribution to the study of the former problem is a systematic confrontation of his own experimental results upon fowls with those of Stockard upon guinea-pigs and of MacDowell upon rats, while the second problem is elucidated by an analysis of statistics of human families collected in Baltimore (a preliminary account of which appeared in our columns on May 31st, 1924).

With regard to the former problem, the principal results are that the immediate effect of alcoholizing parents is to increase pre-natal and neo-natal mortality. It appears, further, that, in guinea-pigs, the average offspring of treated animals are inferior in weight to controls (in rats the controls were inferior), and still show, in breeding, a higher rate of pre-natal or neo-natal mortality. But these disadvantages decrease until in the F4 generation of descendants from alcoholized animals we have an equality in weight and a definite superiority in pre-natal and neo-natal mortality. Dr. Pearl concludes that "the *racial* effect of alcohol is preponderantly either beneficial or, at the worst, not harmful. This is true for characters depending upon general vigour in guinea-pigs (after early generations are passed), fowls, rats, mice, rabbits, insects, and probably frogs." This seems to put the case rather too high. All that Stockard claims, if we understand his argument rightly, is that if a generation of parents be submitted to the action of alcohol and the descendants not exposed to alcohol, then, ultimately, in the fourth generation, we shall have a population superior to the ancestors, inferior variants having been weeded out by the selective action of the drug. It is certainly not proved that if *each* generation were exposed to alcohol we should ultimately produce a better living population. The directly deleterious effect of the drug on each living generation might more than counterbalance the effect of elimination of inferior variants.

Dr. Pearl's contribution to the second problem—namely, the effect of alcohol upon average longevity—is based upon a study of 5,248 individuals derived from the families of (*a*) tuberculous persons, (*b*) non-tuberculous persons taken at random from those who had been before a juvenile court for some trivial offence or registered in the out-patient department of the Johns Hopkins Hospital. This material is very carefully analysed by the appropriate actuarial methods, attention being paid to nature of habits in use of alcohol (whether abstainer, occasional moderate drinker, steady moderate drinker, heavy occasional drinker, heavy steady drinker), civil state, change of habits during life, and so on. It appears that, however analysed, the heavy drinkers showed a disadvantage in comparison with the abstainers, and the moderate drinkers either an equality with or even some advantage over the abstainers. It is quite clear that the material is not, statistically speaking, a random sample of the population, but it also appears that the nature of the selection is not such as to produce a bias in favour of those using alcohol. Hence there seems to be no reason to dissent from the conclusion that, on the average, a moderate use of alcohol does not tend to shorten life. We must, however, demur from Dr. Pearl's phrasing when he writes that "it [that is, this evidence] certainly gives no support to the almost universal belief that alcohol always shortens life, even in moderate quantities." We should have said that such a belief was far indeed from being universal.

In addition to the important new data we have mentioned, Dr. Pearl provides a critical analysis of earlier researches and a useful bibliography. It is very hard to write on any phase of the alcohol problem without ever departing from the objectivity of a man of science, and there are some passages in this book which we could have wished away. But, taken as a whole, it is, we think, a valuable contribution to knowledge, worthy of its author's high reputation, and written with the clarity and grace that always characterize his work.

THE LISTER CENTENARY IN GLASGOW.

GLASGOW, as the cradle of that antiseptic method which abolished hospital gangrene from surgical wards and made the surgery of the cranium, thorax, and abdomen possible, may fitly at this time honour the hundredth anniversary of the birth of the distinguished man whose work in her midst led up to these great developments and heralded the new surgical era. In 1860 Mr. Joseph Lister, an Englishman, who had been house-surgeon under Professor Syme in Edinburgh, was appointed to the chair of surgery in the University of Glasgow. Soon afterwards his colleague the professor of chemistry directed his attention to Pasteur's studies in fermentation and kindred topics. Seizing the principles of these researches, Lister set to work to apply them to the exclusion of germs from surgical wounds. In the wards of the Glasgow Royal Infirmary he initiated antiseptic treatment, using various devices to make it effective. In 1867 he published papers setting forth the record of two years' practice of the new surgery. By 1869,

when he returned to Edinburgh to be professor of surgery there, the foundations of antisepsis had been securely laid. The Lord Lister centenary celebrations in Glasgow will, as mentioned briefly in our last issue, take place on April 1st next. The Lord Provost and magistrates of the city, and representatives of the University of Glasgow, the Royal Faculty of Physicians and Surgeons of Glasgow, and other public and scientific bodies, including the British Medical Association, will assemble in the Royal Infirmary at 10.45 a.m., and walk in procession to the Cathedral close by, in which, at 11.15, a public commemorative service will be conducted by the Rev. Lauchlan MacLean Watt, D.D., Minister of Glasgow, who will preach the sermon. At 1 p.m. the Lord Provost and Corporation of Glasgow will entertain the representatives of the public bodies and scientific societies to luncheon. The illustrious memory of Lord Lister will be proposed at the luncheon by Sir John Bland-Sutton, Bt., ex-President of the Royal College of Surgeons of England. The guests at the luncheon will include Professor Irvine H. Cameron, representing the Royal Society of Canada; Dr. D. Colquhoun, representing the University of New Zealand; and Professor do Quervain of Lausanne. Thereafter the representatives of the various bodies who intend paying homage to Lord Lister's memory will proceed to his statue in the Kelvingrove Park, in front of the high tower of his old University, though not the building he knew, and place their floral tributes at the base of the statue. In the evening at 8.30 the University of Glasgow will hold a reception. The guests will be welcomed by the Principal, Sir Donald MacAlister, Bt., K.C.B., and short addresses will be delivered by Sir Hector C. Cameron, C.B.E., who, as Lister's house-surgeon at the Glasgow Royal Infirmary in 1857, was an eye-witness of these things, Sir George T. Beatson, K.C.B., Emeritus Professor Murdoch Cameron, M.D., and Professor Irving H. Cameron. The bodies participating in the conduct of these celebrations will be the Corporation of Glasgow, the University of Glasgow, and the Royal Faculty of Physicians and Surgeons of Glasgow, which have joined together to commemorate one whose signal achievements have reflected distinction upon the city which cradled his pioneer work.

INDUSTRIAL PSYCHOLOGY.

THE National Institute of Industrial Psychology has just issued its annual report for the year 1926. It covers the sixth year of the activities of the Institute, and discloses a remarkable work done over an extensive field, and a happily increasing appreciation of the practical usefulness and widening promise of such work. The names of the presidents, Viscount Haldane and Sir Charles Sherrington; president of the Institute, the Earl of Balfour; of its vice- of its director, Dr. Charles S. Myers; the list of its council, composed of many of those most eminent in medicine, in science, in industry, in commerce, and in education, are sufficient guarantee of the genuine character and the national importance and scope of its investigations and services. Not so very long ago there was a tendency in some quarters to be sceptical with regard to this. There is no excuse for such scepticism to-day, when even the United States of America, with all its "scientific manage- ment" of industry, is enlisting the services of this British National Institute to correct or replace its own cruder methods. The activities of the Institute may be described as threefold—concerning vocational aptitude, vocational methods, and vocational surroundings. Remarkably suc- cessful results have been obtained, both psychological and economic. It can never be easy to ensure that the right person is doing his appropriate work by the most suitable methods in the best surroundings, but commercial and industrial firms are showing a welcome tendency to seek the services of the Institute in connexion with their enter- prises, and there is scarcely an instance in which the financial return and the output and comfort of the workers have not all been greatly improved as the result of applying the suggestions made and the advice given. The present report records such results in concerns so varied as factories of various kinds, spinning and woollen mills, quarries, oil refining, rubber works, gas works, printing works, motor-car construction, omnibus building, laundries, hotels, retail stores, banks, and offices. The point of view of the workers themselves is well illustrated by comments made to members of the Institute's investigating staff: "Could we not have more like this? It has made it a lot easier for us"; "I wish you had been here when I was a girl; I wouldn't look the old hag I do now"; "How on earth did they get on without you so long?" Such practical work as that indicated necessarily involves, indeed constitutes, research, and much of the vocational selection and guidance is in its nature experimental; it is important and interesting to note that much of it is being done at, or in co-operation with, the Industrial Fatigue Research Board, the Borstal Institution, employment bureaux, and education authorities. Two of the investigations on which Dr. C. S. Myers has himself been engaged, for instance, are the effects of menstruation on mental and muscular efficiency, and the influence of ultra-violet rays on the efficiency of the factory worker. Three separate reports dealing with vocational psychology, very valuable and suggestive, have been published by the Institute. They deal mainly with vocational guidance; and with regard to this the Committee on Education and Industry, in its recent report, says: "We think that the experiments should be encouraged, and we would recommend that local education authorities, juvenile advisory committees, and teachers should make themselves acquainted with the tests which are carried out and the methods adopted." We can unreservedly make the same recommendation to the medical profession.

LIPIODOL.

THE use of lipiodol in many branches of medicine and surgery is now well established, and numerous papers have recently been published on the subject since that by Mr. Sargent which introduced the method to surgeons in this country (BRITISH MEDICAL JOURNAL, 1923, ii, p. 174). At a meeting of the Medical Society of London on March 14th Dr. Jacques Forestier of Paris, one of the originators of the use of lipiodol in radiography, gave an interesting account of its discovery and the various ways of employing it. Six years ago a patient under the care of Professor Sicard was receiving injections of lipiodol into the buttock for thera- peutic purposes, and a chance radiological examination led to the discovery that the substance was opaque. This led Sicard and Forestier to investigate the use of lipiodol, which Sir Percival Hartley described later in the evening as one of the greatest aids to the diagnosis of diseases of the chest which had been discovered in the last twenty years. Dr. Forestier detailed the steps of the evolution of the use of lipiodol, animal experiments being carefully performed in the first instance. The oil itself is prepared from poppy seed; iodine to the extent of 40 per cent. can be combined with it, and is not merely in solution. Its uses in the diagnosis of diseases of the lungs and bronchi were described, and Dr. Forestier indicated the various ways in which it could be injected. The only contraindica- tions in this connexion were advancing tuberculosis with fever and haemoptysis. With regard to the spinal cord, two main routes were used: 1 to 2 c.cm. of lipiodol could be injected into the cisterna and allowed to fall by gravity, or the same amount could be introduced by lumbar punc- ture and the patient carefully tilted on a special x-ray table. In this way complete stoppage of the opaque oil by a tumour could be seen, and also definite x-ray

evidence of even intramedullary tumours could be obtained, when a curious picture of partial blockage was presented. A further development was the use of "light lipiodol," a mixture of lipiodol and olive oil, to inject the ventricles of the brain, since this "light" variety would rise in the cerebro-spinal fluid. By injection into the epidural space in cases of sciatica lipiodol was made to surround the sheaths of the spinal roots, with beneficial therapeutic results. Dr. Forestier, reviewing other uses of lipiodol, said that the nasal antra and sinuses had been injected, and in some cases of disease of the lacrymal ducts it was of value. The injection of sinuses and fistulae by this substance was also beneficial, since it was completely non-irritant. He described one case of deep-seated abscess without a fistula which, by means of lipiodol, was traced to previously undetected spinal caries. The arteries could also be injected, and Dr. Forestier described two striking cases of gangrene of the leg where the exact site of the obstruction was localized in the arteries, leading in one of these cases to successful embolectomy from the femoral artery. In the genito-urinary system lipiodol had also been used to demonstrate diseases of the urethra, ureters and kidneys, and even the vas deferens and seminal vesicles had been successfully injected. Lastly, Dr. Forestier mentioned the injection of lipiodol into the uterus and Fallopian tubes, where it was useful to diagnose tumours in the pelvic cavity and to test the patency of the tubes. Dealing finally with the dangers of the method, Dr. Forestier stated that he had used lipiodol in thousands of cases without any sort of accident, except in one case of injection of the spinal canal followed by slight "shock" symptoms. He had recently searched the bibliography without finding the record of any fatality.

THE PRACTICAL VALUE OF INSULIN.

PROFESSOR MARCEL LABBÉ begins to exercise a kind of appellate jurisdiction in medicine. For instance, a certain number of physicians have been saying that there are cases of diabetes which prove refractory to the action of insulin. An appeal like this against the accepted verdict in favour of insulin needs a judicial hearing. Professor Labbé gives his considered verdict in a communication to the Académie de Médecine. In some cases, he says, where insulin is accused of failure the trouble has been renal glycosuria without hyperglycaemia. Chabanier's suggestion that certain true diabetics have kidneys abnormally permeable to glucose he rejects because it is unsupported by evidence. Hepatic glycosuria is refractory to insulin, but it is not true diabetes, and in some instances true diabetes may be complicated by cirrhosis of the liver, which may delay improvement, though ultimately such cases respond to treatment with insulin. Then Professor Labbé goes on to mention cases of glycosuria which may be refractory owing to disorders of the thyroid, pituitary, or suprarenals. But he points out that glycosuria associated with lesions of the thyroid or pituitary may depend in a measure on failure of the internal secretions of the pancreas. Next he deals with true diabetes complicated by severe infections, and whilst admitting that diabetes may be greatly aggravated by concurrent infection, it does not, he says, become refractory to insulin if only big enough doses are administered. As for diabetes complicated by arterio-sclerosis and nephritis where coma develops, he holds the coma to be due to cerebral haemorrhage or uraemia, and insulin cannot be expected to avert or cure these accidents. Professor Labbé finally discusses the cases of true diabetes where the patients deceive the physician by surreptitiously increasing the diet prescribed. He quotes many examples where insulin has been credited with failure that turned out on closer surveillance to be entirely due to the patient's refusal to submit to dietetic restrictions, or, again, to error on the part of the physician in the regulation of the diet. He concludes by giving as his verdict that there is no case of true diabetes, however severe it may be, that proves refractory to insulin. Professor Marcel Labbé has rendered a signal service to medicine by his careful consideration of a difficult problem and by his authoritative judgement.

THE INFLUENCE OF MANURIAL CONDITIONS ON THE VITAMIN CONTENT OF GRAIN.

THE fact that white bread is almost universally preferred in this country, and that it forms a high proportion of the diet of the poorer urban population, coupled with the further fact that it is deficient in vitamins, has caused many people to be alarmed at the possibility of the total diet of these classes being seriously deficient in vitamins. The dietary problems in this country are, however, trivial compared with those occurring in the East, where populations of many millions restrict themselves to a single cereal as the staple article of their dietary. Lieut.-Colonel McCarrison, I.M.S., who is in charge of the Deficiency Diseases Inquiry in South India, has recently published[1] an interesting paper which opens up many new problems regarding the possible causes of vitamin deficiency. He made experiments to determine the relative vitamin content of millet and wheat grown under varying conditions. Three different cultural methods were tested. The grains were grown on plots of ground which had received no manure for many years, in ground treated with chemical manure, and on plots supplied with cattle manure. The yields of the different plots varied greatly, and the manured plots yielded three or four times as much grain as did the plots without manure. As regards vitamin content, the most striking result obtained was with millet; the grain from the plot which received no manure of any kind appeared to be completely devoid of vitamin B, whilst the content of this vitamin in the grain of the cattle-manure plot was markedly higher than that in the grain from the plot treated with chemical manure. Millet is the staple diet of large populations in the Madras Presidency, and the poor lands in this district have the same general characters as those of the no-manure plot. It is to be noted that beri-beri is endemic in certain areas. These facts indicate the great practical importance of the experimental results obtained. Those with wheat were not so clear. Wheat from cattle-manure plots had a distinctly higher vitamin A content than wheat from chemical-manure plots, but although the no-manure plots gave a very poor yield of grain, yet the wheat obtained had as high a content of vitamin A as the cattle-manure wheat. It seems, therefore, that the influence of manure supply on the vitamin production of grain is complex, and that different cereals are affected in different ways. There are many possible reasons for these differences, but it is evident that McCarrison's experiments have opened up large and important problems, and it is to be hoped that this interesting work will be continued. The vast damage that deficiency diseases have in the past produced amongst Eastern races makes it important to learn as much as possible about the conditions governing the vitamin content of the grains that constitute their dietary.

LESSONS FROM NECROPSIES.

PROFESSOR WILLIAM OPHÜLS of the Pathological Department of the Stanford University Medical School has made a careful statistical survey of 3,000 necropsies[2] performed by him or his associates, mainly in the Lane Hospital or in the San Francisco Hospital, during the years 1900 to 1923.

[1] *Indian Journal of Medical Research*, 1926, vol. xiv, p. 351 et seq.
[2] *A Statistical Survey of Three Thousand Autopsies from the Department of Pathology of the Stanford University Medical School.* Stanford University Publications; University Series, Medical Sciences, Vol. I, No. 3. 1926. (Sup. roy. 8vo, pp. 244; 16 charts. Paper 2.50 dollars; cloth, 3 dollars.)

One-tenth of these were on cases fatal before or shortly after birth, and in more than one-third (112) of these 307 cases the cause was congenital syphilis, so that all other diseases pale into insignificance in comparison as factors in infant mortality—a conclusion which does not appear to be of universal application. The largest number of deaths occurred between the ages of 50 and 55. Taking the cases as a whole, by far the most frequent morbid change was tuberculosis, which was present in 64 per cent. of all bodies, being active in 22 per cent. and quiescent in 42 per cent.; in 82 per cent. of the total it was pulmonary. Septic infections were present in 1,288 cases, or nearly 43 per cent. of the total 3,000. The respiratory tract was affected in 384 cases, or 30 per cent. of the septic cases, there being 200 of bronchopneumonia and 122 of lobar pneumonia (it may be noted that only 38 necropsies were performed during the influenza pandemic of 1918-19); the endocardium was affected in 302 (209 chronic); the liver and biliary tract figured in 103 cases, and the rest of the alimentary tract in 137, the appendix being inflamed in 23 only; but there were also 125 cases of suppurative peritonitis. General arterio-sclerosis occurred in 917 cases, and chronic nephritis in 101; this subject, on which Professor Ophüls wrote an admirable monograph (the first in this series) in 1921, is discussed at considerable length, and a number of interesting points are brought out; among 105 cases of arterio-sclerosis of the cerebral arteries, haemorrhage into the brain occurred in 45 and was recent in 38, thus showing its fatal character. Among 7 additional examples of cerebral haemorrhage the arteries both in the brain and elsewhere were healthy, but in 4 of them there was evidence of high blood pressure, as shown by cardiac hypertrophy; this observation is obviously of interest in connexion with the question whether or not high blood pressure can produce rupture of a normal artery. There were 129 cases of coronary arterio-sclerosis, and in 70 of these specially investigated there were 8 with angina and advanced arterial change, 6 of them with thrombosis. The observations made did not support the view that angina is due to disease of the first part of the aorta. The systems of the body are gone through seriatim, and many deductions useful in medicine can be gleaned from these pages. For example, more than a third of the patients with known chronic alcoholism had excessive accumulations of fat somewhere in their bodies, and a little less than a third of all patients with such fatty deposits were known to have been chronic alcoholics.

SYMPTOMS PROLONGED BY HABIT.

DR. CHARLES FIESSINGER, in a communication to the Académie de Médecine on February 1st, discussed the effect of habit on morbid symptoms. He had already recorded the case of a patient, 66 years of age, who suffered from slowness of the pulse, probably due to arteritis of the small vessel of the bundle of His. The arteritis was cured, but the slow pulse remained, until a new doctor restored the confidence of the patient, and a cachet of theobromine removed the symptom. The patient remained well for eighteen months. The symptoms most likely to be perpetuated by habit were those most accessible to the will. Habit would have less effect on fever than on cough or constipation. Pain that had been relieved by morphine might persist though the cause had been removed; and each successive injection confirmed the habit of pain. Similarly with insomnia, a patient might fail to sleep unless he had taken his cachet. Yet if he ceased to take it, though he might not sleep for four or five days, in the end the habit would be broken and normal sleep would return. In heart disease dyspnoea might continue though the heart had become nearly normal and the kidneys were functioning well. In such cases twenty-five years ago miracles were wrought by the Trunecek serum, which attacked a symptom having no right to exist except in its obstinacy against disappearing. Dr. Fiessinger even thought that a heart could take the habit of dilating; and that some albuminurics passed albumin through habit. The cure of such cases by restoring the patient's confidence had been confirmed by Eichhorst. In cases of habit in symptoms such as those described, the doctor, while prescribing appropriate remedies, would devote his attention mainly to the mentality of the patient. He would try to remove fears, and to break down the habit by emotional reactions. The manner in which these reactions should be provoked depended upon the perspicacity and intelligence of the doctor.

MENTAL HYGIENE AND EMIGRATION.

A most imposing document has been issued by the United States Public Health Department, entitled *Mental Hygiene, with Special Reference to the Migration of People*.[1] It is the work of Dr. Walter L. Treadway, surgeon in the United States Public Health Service. He may well be complimented upon the comprehensiveness of his survey. The emigration law of the United States provides for the appointment of boards of special inquiry. These are composed of immigration inspectors, who determine upon the disposition of all cases of immigrants detained at ports of entry in accordance with the law. Such boards are authorized to determine whether an alien who has been duly held back shall be permitted to land or shall be debarred from entering the country. The decision of a board of special inquiry is often based upon the certificate of medical officers, and, according to law, "shall be final as to the rejection of aliens affected with tuberculosis in any form or with a loathsome or dangerous contagious disease, or with any mental or physical disability which would bring such aliens within any of the classes excluded from admission to the United States." There is a right of appeal from such decisions. Racial groups organize and maintain "machines" for the furtherance of the aims of their compatriots: "Unless one is familiar with these effects, he cannot appreciate the enormous pressure of influences that seek to land excluded aliens." Humanity forbids the return of persons who are actually ill, and for these temporary admission is allowed, but such are the facilities for delay that a mentally defective woman whose deportation was stayed under bond remarried, and is still in the United States after seven years, for each successive order for deportation was postponed on request for re-examination. In the meanwhile she has married and produced two children. "What of her progeny?" asks Dr. Treadway. That is the main thesis of the work: to ascertain the effect of emigration upon mental disease. There are excellent chapters on the conception of mental hygiene, on the policy of public relief of defectives, and in particular the growth of the policy in the States in correctional institutions, the care of the insane, and the education of the feeble-minded. There follow chapters on European ethnology; a description of the ten decades of migration to the States; chapters on the evolution of emigration laws—these began with slave importation and the transfer of criminal prisoners to the colonies; the psychological characters of the racial groups of immigrants; and finally, details of the actual work of the immigration officers and those having the care of the insane. There are immense bodies of statistics, some of them most suggestive. For example, in New York State foreign-born comprise about one-fourth of the general population, but almost one-half of the first admissions to the public institutions for

[1] Public Health Bulletin, No. 153: *Mental Hygiene, with Special Reference to the Migration of People*. By Walter L. Treadway, United States Public Health Service. Washington: Government Printing Office. (Pp. 199. 25 cents.)

mental disease are foreign-born. Further, figures go to show that the admissions of foreign-born are greater in the later years of their residence than in the early. On this is based a suggestion that greater care in mental examinations and more strictness are required. Racial groups show specific liabilities. Syphilitic brain disease is highest among Indo-Eranic, Sinitic, Negritic, Lettic, Finnic, and Chaldaic stocks, low among the Anglo-American stock. Malayic stock is prone to mental disease from traumatism. The Celts seem more prone to develop intoxication psychoses than any other stock; the Irish rank first in disorders due to alcohol, Slavonics are high, the Hellenics, Indo-Eranic, and Chaldaic the lowest.

NATIONAL ASSOCIATION FOR PREVENTION OF TUBERCULOSIS.

THE National Association for the Prevention of Tuberculosis has issued an illustrated historical sketch of its career from its inception in 1898 down to last year. The object of the publication, it would seem, is to invite financial help for a wide extension of propagandist effort. Notwithstanding the assumption by the State and local authorities of responsibility for tuberculosis schemes, the association is convinced that much remains in which voluntary bodies may render assistance. The directions in which the association desires to extend its efforts are in educating every member of the community in the cause and prevention of tuberculosis, and in developing a scheme of tuberculosis care committees throughout the country. A further object of the association is "to render aid to pressing claims for help, communal and individual, . . . when the need cannot adequately be met, if at all, by provisions rendered possible by statute." The pamphlet sets forth a very fine record of work accomplished by the association in diffusing knowledge of the disease amongst the lay population, and in promoting various schemes, national and international, for dealing with the victims of tuberculosis. Under the former heading are the promotion of congresses, beginning with the British congress in 1901, to be followed by international congresses in various countries; the compilation and distribution of leaflets; tuberculosis exhibitions and caravans; lectures and films. To aid in treatment the association has taken up the subject of training for voluntary workers in tuberculosis, and, at the request of the Joint Council of the Order of St. John and the British Red Cross Society, drafted a scheme of training for members of Voluntary Aid Detachments. A tuberculosis survey of England was undertaken on behalf of the British Red Cross Society. A handbook of tuberculosis schemes was prepared in 1916, and a fourth edition of the book was published in 1923. During the war the association urged on the War Office and other authorities the need for providing for the future care of tuberculous ex-service men. The proposals included the establishment of farm colonies, and of homes for advanced or dying cases. The association was able to establish the Burrow Hill training colony in Surrey, and to assist in the foundation of the Southfield sanatorium colony near Edinburgh. Through the activities of branches of the association a number of sanatoriums for the working classes have been opened in various parts of the country. The setting up of tuberculosis care committees throughout the country is regarded as a matter of immense importance, and as essentially work for voluntary associations. The care committees should help the tuberculosis officers to solve many problems for the sufferers from the disease, to re-create disorganized homes, to clear away conditions in which tuberculosis is bred, and to train and guide the young in the selection of suitable and healthy employment. The pamphlet contains many reproductions of photographs of sanatoriums and farm colonies founded by the association and its branches. There are also pictures of royal patrons and presidents, of the late Earl of Derby, and of Sir William Broadbent, the first chairman of council. There are some maps of Great Britain showing, for comparison, the distribution of tuberculosis in 1898 and in 1924. These maps are stippled or lined in various degrees to show local death rates per 1,000 of population. These maps may perhaps be useful for propaganda, but we venture to think that to the casual observer they are liable to be misleading. The 1898 map is heavily lined in almost its whole extent, with one very black patch in the South of Scotland. In the map for 1924 large tracts of country have become pure white, and there is a total absence of heavy lining and of black spots. Yet this represents a country in which over 40,000 people die annually of consumption. The explanation is that the white areas on the map represent a death rate of less than 1 per 1,000 of population, and do not mean that the areas are free from tuberculosis. The association does not, of course, claim that its efforts are the sole cause of the fall in the number of deaths in Great Britain from 70,000 in 1898 to 46,000 in 1923, but no reference is made to the decline in the death rate that occurred before the association began its activities. The statement in the Registrar-General's report for 1920 that there is an "ever-increasing acceleration of the rate of fall" is quite justifiably quoted as it stands. We recall that the drop in the phthisis mortality in the twenty-eight years from 1860 to 1888 was from 2.7 to 1.5. The present mortality is about 0.85.

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY.

FOLLOWING a council meeting in London of the International Society of Medical Hydrology on March 3rd, a conversazione was held at the house of the Medical Society of London, when Dr. Gustave Monod, the president of the society, and Madame Monod received a large company of guests. An exhibition of hydrological interest, arranged by the staff of the Wellcome Historical Medical Museum, consisted of a gallery of old prints illustrating bathing establishments and their procedures in this and other countries, also relics or replicas from the baths and domestic water arrangements of the ancient Romans, and a collection of strigils, gathered over a very wide field of Europe and Asia. The strigil, it will be remembered, is an instrument, in wood or metal, used for scraping the skin at the bath. Another exhibit was a piece of wooden water-pipe of the seventeenth century found during excavations in one of the main thoroughfares of the city of Liverpool. A demonstration with the epidiascope was given to illustrate the life-history of silica, from the colloid to the crystalline form, and including what was described as the birth, life, and death of the opal. The lecturer, Mr. Lewis Abbott, F.G.S., explained how the chemicals taken up by the percolating waters gave rise to medicinal springs, and how the jasper and sapphire are related to the pebbles of the brook. One or two members of the society from abroad spoke in their own languages a few complimentary remarks, and a cinematograph film was shown depicting the events of the annual meeting of the society held last year at the invitation of the Czech Government and spa authorities, and attended by representatives of thirteen countries. Dr. Monod is now relinquishing the chair of the society, and in a few valedictory words he spoke of the pleasure it had given him to preside over a society which was founded in Great Britain, and which now had its members in twenty-four countries, having grown more quickly than its promoters had ever anticipated. The object of the society, he said, was to place on an increasingly scientific basis the oldest natural methods of treatment—water, air, and light, or, to quote St. Francis,

"Brother Sun, Brother Wind, and Sister Water." He also announced that the society would hold its next annual meeting in Italy in October next, and that its new president would be Professor U. Gabbi, a distinguished Italian hydrologist.

We regret to have to record the death of Dr. Corrado Da Fano, Reader in Histology, King's College, London. He was well known for his work in neurology. We hope to publish a notice of his life in an early issue.

"THE FATHER OF TROPICAL MEDICINE."

A MANSON MEMORIAL: MR. NEVILLE CHAMBERLAIN'S TRIBUTE.

At the Albert Dock Hospital, London, on Tuesday afternoon, March 15th, Mr. Neville Chamberlain, the Minister of Health, unveiled a tablet to the late Sir Patrick Manson. The tablet, which is placed in the ward where Manson for a number of years practised and taught, is a very simple work of art, embodying a medallion portrait in bas-relief, and the words: "Sir Patrick Manson, G.C.M.G., F.R.S., The Father of Tropical Medicine, Physician to this Hospital, 1892-1922." Among those present at the ceremony were:

Mrs. Carnegie (formerly Mrs. Joseph Chamberlain), Sir Ronald and Lady Ross, Dr. and Mrs. Manson-Bahr, Sir Humphry Rolleston, Sir James K. Fowler, Dr. Andrew Balfour, Sir William Simpson, Sir Wilmot Herringham, Colonel and Mrs. Alcock, Admiral Sir Henry Jackson, Dr. F. E. Fremantle, M.P., Dr. F. N. Kay Menzies, Professor C. J. Martin, Dr. A. G. Bagshawe, and the Chinese Chargé d'Affaires and the Siamese Minister.

Mr. CHAMBERLAIN, who was invited by Sir Arthur W. Clarke, chairman of the Seamen's Hospital Society, to unveil the tablet, described Manson as one of the great benefactors of the human race. His name had been familiar to him from the closing years of the last century, when his father, Mr. Joseph Chamberlain, appointed Manson medical adviser to the Colonial Office. In those days tropical diseases were little understood; the symptoms of many of them would not have been recognized by the majority of medical practitioners, and malaria, the greatest scourge of tropical lands, was supposed to be due to some poisonous exhalations arising in marshy districts. But Sir Ronald Ross was working out his observations upon the natural history of the malarial parasite, and eventually showed that the parasite was communicated from man to man through the agency of a species of mosquito, in whose body it underwent an essential part of its existence. That discovery was quickly followed by the initiation of measures for the destruction of mosquitos in fever-infested localities, and the mitigation, if not the total suppression, of the disease in many places where it had been almost impossible for the white man to live. This work was a tremendous stimulus to the imagination of the medical profession. A whole army of investigators entered into the field, and began to consider whether the establishment of the biotic connexion between man and living organisms in the propagation of disease might not have many other illustrations; their efforts were rewarded with extraordinary success. In medical science no one section could be isolated, and these discoveries, originating in the study of tropical diseases, had their repercussion in diseases of temperate climates, so that it was difficult to estimate the number of lives which had been saved in all parts of the world as a result of these relatively early discoveries in tropical medicine.

Of all the labourers in this field (Mr. Chamberlain continued) Patrick Manson might truly be said to be the father. He was a Scotsman, born in Aberdeenshire, originally intended for engineering, and embracing medicine because prevented by physical weakness from following the other profession. For twenty-three years he lived in China, on the island of Formosa, or on the mainland at Amoy, or in the British settlement of Hong-Kong. It would be difficult to find a less favourable environment for research work, cut off from contact with scientific society and overwhelmed with the routine of a busy practice; but he found time to pursue his observations upon the unfamiliar diseases of the East, with inexhaustible patience and ingenuity. The whole story of his work was told in the extremely interesting biography just published from the pen of his son-in-law Dr. Manson-Bahr, in collaboration with Colonel Alcock. Mr. Chamberlain thought the most dramatic incident in that story concerned the clue by which this medical detective arrived at a solution of his problem. He was examining the blood of many infected people suffering from filaria, and he employed two assistants, one of whom took samples in the daytime and the other in the evening. The second was singularly successful in finding the filaria, whereas the first had almost barren results, and from this discrepancy Manson discovered what might be called a periodicity in this organism similar to that which existed in the mosquito's habits. Manson came back to England in 1899, and three years later was appointed consulting physician to the Albert Dock Hospital. Mr. Chamberlain believed that it was only after his return that he became acquainted with Ronald Ross. With extraordinary generosity he offered Ross the results of his knowledge and experience, and gave him the utmost encouragement to pursue his investigations on the malarial parasite and the mosquito. A correspondence ensued between the two men, lasting over four years, and marked on both sides by a fine unselfishness, freedom from jealousy, and devotion to the public good. The association of Manson and Ross reminded him of that of Darwin and Wallace, in both cases a noble example of which their countrymen did well to be proud. In 1897 Manson was made medical adviser to the Colonial Office. He was impressed by the fact that medical officers went out to different parts of our tropical empire without any opportunity beforehand of learning of the diseases which were common there. In his efforts to remedy that state of affairs he was supported by Mr. Joseph Chamberlain, who had been appalled by the mortality among the officers sent out to West Africa and elsewhere: and there was a third party to the success of the project, the Seamen's Hospital Society. In 1899 the London School of Tropical Medicine was opened. It began with 27 students, and now 3,000 men had passed through it. In Manson was to be recognized a patient investigator, who greatly enlarged the sphere of knowledge, a very human gentleman, who was an example to those who worked with him and under him, and would remain an inspiration to those who came after him, and one of our great empire-builders not by reason of his conquest of other peoples, but by the victories he had won over some of the most distressing plagues which afflicted mankind.

The vote of thanks to Mr. Chamberlain was proposed by Dr. G. C. Low, senior physician to the hospital, who said that, strange to say, this teaching scheme met with unexpected opposition from some members of the medical profession in London. Sir Patrick Manson had shown his great strength by finally wearing down this opposition. Dr. Low also gave a description of the master among his students in the very ward in which the memorial was set up. The resolution was seconded by Professor R. T. LEIPER, who said that for nearly twenty years he had the opportunity and the joy of working with that warm-hearted and inspiring personality whom they were honouring that afternoon. It was appropriate that the memorial should have its place in the ward of the hospital rather than on the wall of the adjacent laboratory, for Manson was first and foremost a great physician and a great teacher, and as a teacher he not only dispensed technical information while exhibiting his professional skill to his students, but laboured unceasingly to utilize his ever-increasing influence to secure privileges and opportunities for research for all who by their earnestness and sincerity appeared likely to profit by them. Mr. CHAMBERLAIN, in reply, said that he realized he was following a family tradition in taking part in that function that afternoon, and it would be the greatest happiness to him if in any way he could help in the furtherance of what was called the Manson tradition.

THE BLEACHING OF FLOUR.

IN June, 1924, the then Minister of Health, Mr. Wheatley, extended the reference of the Departmental Committee inquiring into the use of preservatives and colouring matters in food, and instructed it to consider "Whether and to what extent the practice of treating flour with chemical substances is objectionable on grounds of health, and whether it is desirable in the interests of the public health that the practice should be prohibited or restricted, and in the latter case what restrictions should be imposed." The Committee was constituted as follows:

Sir H. C. Monro, K.C.B., *Chairman*; Professor W. E. Dixon, O.B.E., M.D., F.R.S., Sir A. D. Hall, K.C.B., LL.D., F.R.S., J. M. Hamill, O.B.E., M.D., D.Sc., P. A. Ellis Richards, F.I.C., Professor Sir F. G. Hopkins, M.B., F.R.C.P., F.R.S., G. R. Leighton, O.B.E., M.D., A. P. Luff, C.B.E., M.D., F.R.C.P., Charles Porter, M.D., B.Sc., G. Stubbs, C.B.E., F.I.C.

The Committee made an interim report, on the use of formaldehyde as a preservative for food, in August, 1924 (BRITISH MEDICAL JOURNAL, August 16th, 1924, p. 289), and the final report of the Committee on its original reference was published at the end of October, and noticed in the JOURNAL of November 1st, 1924 (p. 828). Its report on the additional reference has now been published.[1]

Perusal of the report shows that the inquiry was of a highly technical nature, and that it involved many commercial problems and questions of vested interests. The Bread Act of 1822 and 1836 makes it an offence to sell bread with other constituents than certain substances named, and although this was amended in 1922 in favour of self-raising flours, yet the treatment of flours with chemical agents has been continually increasing. English-grown wheat forms about one-fifth of the total milled in this country: the annual British milling output represents about twenty-two *million sacks, the imports only five or six million sacks.*

The characters necessary in flour used for bread making are that it shall have the capacity to make a large well risen loaf of good texture which shall be white in colour. Flours deficient in these characteristics are frequently treated with chemical agents which may be either bleaching agents or "improvers" or both. The principal bleaching agents in use are nitrogen peroxide, benzoyl peroxide, chlorine, and nitrogen trichloride. The last two substances are often called maturing agents; they both bleach and "improve," but they may be considered for discussion here as bleachers. Bleaching was introduced into this country about twenty-two years ago to meet a demand for white bread, particularly among industrial and manual workers in the North of England. Flour, after milling, changes slightly on keeping, its baking qualities improve, and its colouring matter is bleached. This natural ageing is probably an oxidation process, and imported flour from America and Australia is kept sufficiently long to exhibit this ageing effect. British flours, which cannot easily be kept because of the absence of storage facilities and because of expense, are in this respect at a disadvantage regarding colour; nevertheless, some imported flour is bleached before reaching this country. Hence the practice of bleaching enables millers to compete with importers of flour which has the natural advantage of ageing.

Bleaching Agents.

Bleaching eliminates the difference in appearance between the higher and lower grades of flour from the same wheat. The higher grades, which are obtained from the hardest part of the endosperm, called the semolina, are not only harder but produce a lighter coloured flour; these are known as "whites" or "patents," and total about 50 per cent. of the flour milled; the remainder are known as "households." From the latter and softer flour the offal is less perfectly separated. By the use of bleaching it has been said that a proportion of the "households" can be made to simulate patents, and a "longer range of patents" can thereby be obtained. It is said that a 60 per cent. extraction of the wheat can by means of bleaching be made to look better than a 50 per cent. extraction without bleaching.

Chlorine bleaches by combining with the colouring matter of the flour (carotin), but it also combines with other constituents of the flour. It is known that chlorine can act on the tyrosin and tryptophane groupings of the gluten complex with injurious results as far as the nutritive value of the gluten is concerned. Besides these there are other and more subtle substances in flour, the vitamins, which are known to be very susceptible to traces of chlorine; these also may be destroyed, and so impair the nutritive value of the food which contained them. Although these changes would occur probably in the commercial treatment of flour with chlorine to a limited extent only, yet it is a serious consideration in the case of a food so important as bread.

The same considerations apply to nitrogen trichloride. This body is much more highly reactive than chlorine, and the amount of it used per sack is consequently less. Nitrogen trichloride is introduced into the flour in air saturated with moisture. It is used in proportions varying from one to four grams per sack, and is converted to ammonium chloride and hydrochloric acid in the flour. It gives the effect of ageing in respect of bleaching, and it also improves the baking qualities of the flour.

Benzoyl peroxide, after bleaching the colouring matter in the flour, remains as benzoic acid, and although the amount is small it is better that flour should not contain benzoic acid.

Nitrogen peroxide, like the other bleachers, oxidizes the carotin in the flour. It is less reactive with proteins and fats than chlorine; it leaves nitrites in the flour, though very little—not more, perhaps, than two or three parts per million. The Committee regards nitrogen peroxide less unfavourably than the other bleaching agents.

"Improvers."

The substances used as improvers are principally chlorine, nitrogen trichloride, acid calcium phosphate, acid ammonium phosphate, and persulphates, besides extracts of malt and wheat germ. It is claimed for improvers that they enhance the natural baking qualities of flour by yielding well risen loaves of good volume and symmetry, of satisfactory texture, and of even aeration. "Strength" is the term applied to flours possessing this character, and it depends on the qualities of the contained gluten. Some wheats, notably English, are weak, but the properties of the gluten can be altered by the addition of certain salts and acids to the flour. It is claimed that by the use of improvers a more varied supply of wheats can be used and blended, and a flour of uniform baking quality thus maintained. It is claimed also that the improver promotes the growth of yeast, and so improves aeration. It is established that improvers do improve, though how they act is more difficult to define; one important factor is the degree of *acidity* expressed in terms of *p*H. It is known, for example, that acid phosphates cause dispersed gluten to cohere, but another explanation ascribes the gluten change to oxidation. On the other hand, *the yeast-food type of improvers,* like malt extract, are easier to explain, and their value is most pronounced in those flours that give a small loaf. Much, of course, can be done by judicious blending of weak wheats with strong wheats like Manitoba, but millers want to be in a position to take advantage of any wheat that is on the market on a particular day, and to be free to use improvers so as to be able to make the cheapest flours on that particular day.

Against the use of improvers it may be said that they are not normal constituents of genuine flour; phosphates do not, so far as we know, occur in the flour as such: improvers allow a larger number of loaves to be made from the sack principally by adding to the water: flour from weak wheats, which are usually poor in gluten, contains less protein than flour from strong wheats: by the use of improvers flour from weak wheats is made to simulate flour from stronger wheats, though it is inferior in protein content. The Committee expresses the opinion that millers "are content rather to use more of what they themselves would call inferior wheats, relying on chemicals to make up the baking quality to the old standard."

[1] H.M. Stationery Office, or through any bookseller, price 6d.

The saline improvers probably affect the composition of flour little, and the changes they produce are recognized only by the alteration of those characters which are responsible for strength in flour. Nevertheless, demonstrations were made to the Committee of the serious effect of acid calcium phosphate on the mucous membrane of the alimentary canal. The Committee did not, however, think that in the amounts in which it was added to ordinary flour it could be very harmful (0.5 per cent.).

Physical Methods of Improvement.

The Committee has had under consideration physical methods for improving flour, and thinks that the results already obtained in this direction are promising. For example, it has been shown that improvement in strength of a flour can be obtained by heating the flour under certain conditions; that is to say, flour overheated by artificial means itself acts as an improver. After a warm harvest English wheat produces a stronger flour than after wet and cold harvests; it is suggested that this may be due to partial heat-coagulation. But whatever the explanation, there is hope in the future that improvers will be diminished or eliminated by the addition of a proportion of physically treated flour to each sack.

The Committee concludes its report by stating that it considers that a staple and indispensable foodstuff such as flour, the purity and wholesomeness of which are of cardinal importance to the community, should be jealously guarded against unnecessary treatment with foreign substances, but is not prepared, on the present knowledge available, to recommend the complete elimination of the bleaching agents and improvers now in use.

It advises that chlorine, nitrogen trichloride, and benzoyl peroxide should be forbidden. It recommends that it should be compulsory for the manufacturers of chemical substances for use either as bleaching agents or improvers or both to declare to their purchasers the nature of the ingredients of which they are composed, and that millers should be required to inform their customers whether their flour has undergone a process of chemical bleaching or improving or both, and, if so, with what substances and in what proportion.

Scotland.

JUBILEE OF THE ODONTO-CHIRURGICAL SOCIETY.

THE Odonto-Chirurgical Society of Scotland celebrated its diamond jubilee at its meeting on March 11th, when a dinner was held in the Hall of the Royal College of Surgeons, Edinburgh. The society originated on March 13th, 1867. The toast of "The Society" was proposed by Dr. Parfitt, president of the Odontological Section of the Royal Society of Medicine, and the toast was acknowledged by the chairman, Dr. L. C. Broughton Head, L.D.S., president of the Scottish society. During no period in the history of medicine had there been so great an advance in knowledge and so beneficial an effect on mankind as in the sixty years of the life of this society. Three new sciences—bacteriology, radiology, and biochemistry—had grown up during this period, and all of them had affinities with dentistry. An important experiment in the education of the public in medical matters had recently been instituted by the British Medical Association by the establishment of the Hastings Lectures. The first of these was that on cancer, given by Sir Berkeley Moynihan (SUPPLEMENT, January 29th, p. 29) a few weeks ago to a large audience of the general public assembled in the Great Hall of the Association's new house. Sir Berkeley Moynihan had justly emphasized the necessity of the public seeking medical advice at the earliest sign, but the speaker ventured to think that something further ought to have been said of long-continued diseased conditions of the teeth and gums as an antecedent or predisposing condition to cancer, not only of the mouth, but of the important organs of the alimentary canal. He thought that in this matter the dental surgeon should sound a note of warning both to the public and to its medical advisers, and suggest that efficient dental treatment during early adult and middle life might play an important part in averting the onset of cancer in the later years of life. Mr. J. S. Amoore, L.D.S., proposed "The Royal College of Surgeons," and deprecated any lowering of the standard of examination for the licence in dental surgery. Mr. Alexander Miles, F.R.C.S., who replied, said that whatever political influence might be brought to bear the College of Surgeons would not allow the diploma of dental surgeon to deteriorate in any way. "The Edinburgh Dental Hospital" was proposed by Dr. G. T. Goldie and acknowledged by Dr. William Guy, F.R.C.S., dean of the Dental School. He said that on a recent visit he had conceived a great admiration for the dental institutions of America, but at the same time he felt that in this country, although no great sums of money were expended, a sufficient number of dental surgeons were turned out regarding whose competence there was not the slightest doubt. He believed that in the prevention of disease there was no more potent instrument than the dental surgeon.

GLASGOW ROYAL ASYLUM.

In his report to the annual general meeting of subscribers to Glasgow Royal Asylum Dr. Henderson, the medical superintendent, stated that 681 patients had been under treatment during the year, the average number resident having been 533. The problem of mental disorder and defect, he said, was more far-reaching than that of cancer, for which appeals were being made in regard to a combined attack on the causes, and co-operation in finding out the treatment of the disease. Mental disease similarly demanded co-operation between the medical profession and the public, because of its widespread direct and indirect effects. Treatment at the present time in many cases was too long delayed. If mental disorder in its beginnings were admitted instead of being hidden it would be easier to exert a beneficial influence on the individual's life. Students of medicine, teachers, clergymen, and the public at large should be made familiar with this fact, and education in the sense of character building should be the watchword of those who dealt with mental illness. People should be brought to recognize that mental disorder was not different from any other type of illness, and that it sprang, in the majority of instances, from modifiable factors.

ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.

A new wing has been added to the Royal Samaritan Hospital for Women in Glasgow, and the nurses' home has been considerably enlarged. These extensions were opened on March 4th by Lady Blythswood, who mentioned the great success of the bazaar held in 1924, when £78,000 had been raised in three days. Help had been received also from the police, who collected over £8,000, and from the staff and employees of the corporation tramways, who had contributed more than £1,200. Sir John Stirling-Maxwell, president of the hospital, gave a summary of its history during its existence of forty-one years, and referred to the fact that Dr. Halket, who was the first physician to the hospital, was now its consulting physician. The whole cost of the new building—about £80,000—would be met from the fund raised in 1924 and the interest which had accrued to it, though an additional annual sum of £6,000 would be required for the upkeep of the new wards. In spite of the fact that eighty new beds had been added to the institution by the present extension, there would still be a long waiting list, and he expressed the hope that a convalescent home might later be provided so as to enable patients to pass more rapidly through the wards.

SCOTTISH MIDWIVES BILL.

The text has been issued of the Midwives and Maternity Homes (Scotland) Bill. It consists of two parts, of which one amends the Midwives (Scotland) Act of 1915, and brings it into greater conformity with the practice of England,

while the second deals with the registration and inspection of maternity homes. An important clause (Clause 1) is that prohibiting anyone not a certified midwife under the Act from attending a woman in childbirth, otherwise than under the direction and personal supervision of a duly qualified medical practitioner. Except as regards attention given in a case of sudden and urgent necessity, attendance by any other person involves a penalty not exceeding £10. This does not, however, apply to persons undergoing training with a view to becoming duly qualified medical practitioners or certified midwives. In cases where a midwife has been suspended from practice in order to prevent the spread of infection, if she herself was not in default, authority is given in Clause 3 to the local supervising authority to pay her such amount by way of compensation for loss of practice as is reasonable in the circumstances of the case. The Central Midwives Board for Scotland may, if it thinks fit, divide the roll of midwives into two parts (Clause 5)—one containing the names of practising midwives supplied to the Board by local authorities in January of each year, which is to be published annually, and another part containing the names of other persons entitled to be on the roll, which will be published at intervals not exceeding five years. Power is also given to the Central Midwives Board to institute inquiries by registered letter addressed to anyone whose name is included in the roll with a view to finding out whether she has ceased practice or has changed her address, and failing a reply within six months, to erase the name from the roll. Power is also given to the Central Midwives Board for Scotland to frame a rule as to the wearing of badges by certified midwives (Clause 6).

The second part, dealing with the registration and inspection of maternity homes, is of more general interest to the medical profession. It provides (Clause 8) that any person who after the appointed day carries on a maternity home, unless that person is registered in respect of the home, shall be liable to a fine not exceeding £50, or in the case of a subsequent offence to imprisonment not exceeding three months. Application for registration is to be made to the local supervising authority and is to be accompanied by a fee of 5s. The authority is to have power to refuse registration where it is satisfied that the applicant is not a fit person, by reason of age or otherwise, to carry on a maternity home, or for any reasons connected with the situation, construction, accommodation, staffing, or equipment which appear in any way improper or undesirable in the case of a maternity home. The local supervising authority may also at any time cancel the registration of any person for any reason which would entitle them to refuse an application for registration (Clause 9). Before exerting this authority in either of these matters the local supervising authority shall give to the applicant or to the person registered not less than fourteen days' notice (Clause 10), setting out its reasons and giving the person concerned an opportunity of showing why such action should not be taken by the authority. The authority must also in such cases give the person an opportunity of being heard, and the order refusing an application or cancelling registration shall not come into force until the expiration of fourteen days from the date on which the order was made, or until an appeal has been decided or withdrawn. Any person aggrieved by an order under this section may also appeal to the sheriff within fourteen days, and the decision of the sheriff shall be final and be given effect to by the local supervising authority. Powers are also given, in Clause 11, to the Scottish Board of Health to make regulations with respect to records to be kept by the staff of the home, notifications of death, and prescribing. Persons contravening the provisions of such regulations shall be liable to a fine not exceeding £5, or, in the case of a continuing offence, to a fine not exceeding £2 in respect of each day on which the offence continues after the date of conviction. Maternity homes may be inspected by an officer authorized by the Scottish Board of Health (Clause 12). A local supervising authority may, however, grant exemption from the operation of this part of the Act in respect of a hospital or institution not carried on for profit or not used mainly as a maternity home (Clause 14).

Ireland.

Clean Milk Supply.

Giving evidence before the Advisory Committee (Irish Free State) on the milk supply on behalf of the Dublin Cowkeepers' and Dairymen's Association, Mr. J. Hanly, F.I.C., F.C.S. (chief chemist to Messrs. J. Bibby and Sons, Liverpool), said that the present presumptive standards of quality were unsatisfactory to the producer, the consumer, and the administrator. There were no means by which adulterated milk could, with certainty, be distinguished from milk of naturally poor quality. Consequently it was usually impossible to prove that adulteration or abstraction of fats had taken place. Criminal proceedings were not fitted to such cases, and the matter should be regulated by contract, the producer giving an undertaking to the local authority to deliver milk of a fixed minimum quality. Such minimum should take into account the normal seasonal variations in the composition of milk, and, in his opinion, might average 3.2 per cent. for fats over the full year. The remedy for failure should take the form of a rebate payable to the local authority by way of compensation for administrative cost of maintaining the contract standard, and of such amount as to render a breach of contract unprofitable.

County Medical Officers of Health (Irish Free State).

A deputation from the General Council of County Councils waited on the Minister of Local Government and Public Health, Mr. S. Burke, in connexion with the appointment of county medical officers of health for the Irish Free State. Senator Kenny, in introducing the deputation, said that, generally speaking, the attitude of the council was favourable. When the matter was first considered in 1923 the reports and recommendations of the Public Health Committee were discussed. One recommendation was that the net cost should be borne half by the State and half by the county council, and this was approved, but the Act of 1925 provided that the salaries of county medical officers were to be paid by the county councils, and charged on the area in which they acted. Some of the councils thought that the appointment of these officers should not be taken out of their control; the councils which opposed the scheme did so generally on the ground of the extra expense involved. They estimated that the new appointments would involve other appointments, and that the total cost might amount to £3,000. Various schemes, each possessing a considerable amount of merit, had been opposed on the plea that the financial position would not warrant any extra expense. The Minister, in reply, said that he appreciated the points raised; his department had always been sympathetic with the financial difficulties that arose. However, this scheme was now law; it had been passed by the Oireachtas, and it was his duty to enforce it. It was necessary to make a beginning, and three appointments had already been made. The present medical officers were not able to cope with the situation, particularly as regards the preventive side of the medical service. When fevers broke out the local officers had not got adequate machinery, as instanced by the present outbreak of typhoid in county Cavan, and of scarlatina in the counties Longford and Kerry. County medical officers would be able to deal with the situation. There was also the commercial aspect, which would become more important as time went on. At present the produce of the Free State enjoyed a very favourable position in the English market—better than any of the colonies. He did not want to be alarmist, but it was necessary to stress the point that if medical inspection in the Free State was not brought up to a level with the English inspection it was quite possible that produce would be put under a ban, particularly pork and butter. The report of an inspector from the United States of America upon some Free State meat factories was not very favourable. On the question of costs, he said that officers were being appointed, not to set up an elaborate public health machinery, but

to a great extent to avoid doing so. It was altogether an exaggeration to say that the cost would run into £3,000; 50 per cent. of any expense, other than the £800 salary, would be borne by the State. He also pointed out that the agricultural grant had been doubled in recent years.

England and Wales.

SICK AND AILING CHILDREN IN LIVERPOOL.

THE annual reports of the various children's hospitals and homes on Merseyside demonstrate the great amount of medical attention which is demanded. The out-patient departments of the Royal Liverpool Children's Hospital, Myrtle Street, and the Birkenhead and Wirral Children's Hospital dealt during the past year with nearly 30,000 new cases. This number is large, but mere figures, however steadily increasing as years go by, do not give an altogether just index to the increasing work. The development of prophylactic medicine is particularly marked in childhood, and an ever-increasing number of patients at hospital clinics are not seriously ill but are brought there as a preventive measure. The necessary medical detailed examination is often as a consequence exacting. At the Liverpool hospital an [illegible] department has been established and [illegible] apparatus extended; in connexion with the Birkenhead hospital a new convalescent home is to be opened during the summer. At the Heswall branch of the Royal Liverpool Children's Hospital extensive developments are in progress, which it is expected will ultimately add three new wards to this open-air establishment. Corresponding extra accommodation is being provided for residents, nurses, and maids. Both at this hospital and at the Liverpool Open-air Hospital for Children, Leasowe, an increasing amount of orthopaedic work continues to be done in conjunction with various authorities and councils. At the West Kirby Convalescent Home, at the Royal Liverpool Children's Hospital at Heswall, and at the city children's hospitals in Liverpool and Birkenhead, very large numbers of rheumatic cases are dealt with. During the past year the honorary physicians on the staffs of the four institutions, together with a small body of research workers, have determined and set in action a concerted plan of campaign dealing with rheumatic and heart cases, and in conjunction with the medical officers of health for Liverpool, Birkenhead, Bootle, and Wallasey are developing this work.

COUNTRY HOSPITAL FOR CRIPPLES IN NOTTINGHAMSHIRE.

The interest of the Duke and Duchess of Portland in the treatment of cripples in Nottinghamshire has led them to offer a site in Harlow Wood, between Nottingham and Mansfield, for the erection of a special country hospital school for cripples. A representative county committee has been formed, and it is hoped to raise the sum of about £30,000, of which £24,000 will be required for the building and £6,000 for equipping it on the most modern lines with an operating theatre and electrical and radiological departments. The locality is very suitable for treatment by fresh air and sunlight, and it is recognized that educational facilities must be provided. It is estimated that at present there are in the city of Nottingham alone more than 100 cripples who, for lack of such an institution, are unable to receive the prolonged residential treatment which they need, in spite of the activities of the out-patient clinic of the Nottingham Cripples' Guild, and the affiliated clinics at Mansfield, Newark, Worksop, Hucknall, and Loughborough. The new hospital will be the centre for all orthopaedic work in the district, and will undertake the treatment of inflammatory conditions of the bones and joints, deformities of all kinds, and the various forms of paralysis. The Nottingham Cripples Guild commenced its work in a small way with the provision of crutches, instruments, and bath chairs. Its present clinic in Park Row was erected at a cost of between £4,000 and £5,000, and was opened a year ago. Since then the average weekly attendance has been 274, the majority of the patients being children. The health, education, and Poor Law authorities have co-operated actively in its work.

Union of South Africa.

[FROM OUR CAPETOWN CORRESPONDENT.]

THE UNIVERSITY OF CAPETOWN.

AT the graduation ceremony of the University of Capetown in December, when the Vice-Chancellor (Sir J. Carruthers Beattie, D.Sc.) presided, the address was given by Professor W. A. Jolly, LL.D., D.Sc., dean of the Faculty of Medicine. In an eloquent plea on behalf of the extension of research work, referring in particular to medical science, Professor Jolly said it could justifiably be claimed that much advance had been made in medical knowledge in recent times. Diseases which were baffling until the other day could now be met and overcome, or, better still, prevented, but what could as yet be done was as nothing to what would be done when more was known, and increased knowledge could only be got by investigation. "Suppose," Professor Jolly continued, "you are attacked by disease and a cure is effected, you are naturally grateful, but if you are only cured and nothing more is done with your case, then you are justified in bearing a grudge against the medical profession. You may be attacked by the disease again and not recover, or your relatives or friends may die of it. If your case has not been studied and recorded with a view to our learning more about the disease, so that humanity in time may be rid of it, then the community has failed in its duty. It would be well that hospital authorities should grasp this aspect of the matter. If we take a broad view it is comparatively a small thing that individuals should be helped. We cannot be satisfied with the present state of affairs. The present, with its dirt, disorder, and disease, is a nightmare. We must work towards a happier, healthier world in the future, when we shall have the foul thing disease more effectually by the throat."

Prior to the constitution of the congregation, Professor Jolly was presented with the LL.D. hood and gown by the members of the Medical Faculty. The presentation was made by the Vice-Chancellor, and Professor M. R. Drennan also spoke.

INFLUENZA.

The Secretary for Public Health for the Union has issued the following circular as to influenza:

"I am directed by the Minister of Public Health to draw attention to the prevalence of influenza of severe and epidemic type in certain parts of Europe, the increase of notifications of and deaths from this disease in Great Britain, and the risks of introduction of the infection into South Africa.

"The greatest vigilance is being exercised, and all practicable measures and precautions taken at the ports of the Union to prevent such an eventuality, but the nature and extreme diffusibility of the infection of epidemic influenza are such that, short of wholesale quarantining of arriving vessels (which would entail enormous expense and paralyse the oversea trade of the Union), the exclusion of the infection at the ports cannot be guaranteed. It is therefore desirable that local authorities and all others concerned should review and overhaul their organization, facilities, and resources for dealing with a possible outbreak—especially as regards the enlightenment of the public as to the nature and dangers of the disease and precautions to prevent spread, the treatment and care of the sick in their own homes, and the accommodation, nursing, and treatment of cases requiring removal to hospital.

"This department is keeping in close touch with developments in Europe, and has arranged for obtaining weekly telegraphic reports during the continuance of the prevalence, and for the immediate cabling of particulars of any development of special importance in Europe; these reports will be published in the press, and all necessary steps taken to keep local authorities and the public of the Union fully and promptly informed. It is not thought that the position at present is such as to cause anxiety or to necessitate expenditure by local authorities on the employment of special staff or on stores or equipment (especially if of a perishable nature, or liable to deteriorate with keeping), but it does call for vigilance, preliminary preparation, and special activity as regards sanitary and housing conditions and overcrowding, and for the preliminary preparations for dealing with a possible outbreak."

Local authorities in Capetown are fully alive to the possibility of an outbreak occurring with little warning. The city council, it is satisfactory to note, has acted wisely in approaching the local branch of the Medical Association of South Africa, inviting the co-operation of the medical profession in the preparation of a scheme of emergency measures should the threatened danger materialize. The details of such a scheme are to be discussed at a special

meeting of the branch council of the Medical Association. The matter has been discussed also at a recent meeting of the Cape Divisional Council, a body which administers the affairs of the rural areas in the Cape peninsula.

KIMBERLEY HOSPITAL.

A service was held recently in the chapel of the Kimberley Hospital at which a memorial was dedicated by the officiating minister, the Very Rev. T. C. Robson, to the memory of the late Dr. E. O. Ashe, who was closely associated with the hospital for many years. The memorial, which is a beautiful rose-window, was given by Mrs. Ashe. It was designed by Mr. W. M. Timlin and executed in England by the Birmingham Guild.

The question of rendering the Kimberley Hospital fly-proof has been under consideration by the hospital board for some time, but financial stringency has so far prevented the scheme from being put into effect. Now the welcome intimation has been received that the De Beers Company is prepared to contribute a sum of £200 towards the cost of the project; this offer is the outcome of a promise made by the chairman of the board some six months ago. Without doubt this scheme when completed will add greatly to the comfort of the patients and staff, and the generosity of the company is on that account much appreciated.

APPOINTMENT OF A SUPERINTENDENT AT THE CITY HOSPITAL.

The wave of nationalism—the word is used not in any political sense—pervading the country at the present time is responsible for an unfortunate controversy which has arisen in local medical circles over the question of the appointment of an overseas applicant to the position of medical superintendent of the City Hospital for Infectious Diseases, Capetown. Following the resignation of Dr. W. P. Cooney, who held the appointment, the city council through its responsible committee advertised both locally and overseas for a successor. It would appear that seven applications were received locally and nine through the London agents. After due consideration, and having interviewed four of the South African candidates, the Health and Building Regulations Committee recommended to a meeting of the city council that a certain medical man from England be appointed. This evoked a heated outburst on the part of several councillors, who in very strong terms deprecated the fact that local applicants had been passed over. It was held by them that at least one of the latter was sufficiently well qualified and had had adequate experience for holding the position in question. After a lengthy debate, in the course of which accusations were made and apologies accepted, a ballot was held, the result of which showed 21 votes for the overseas candidate, and 14 and 1 respectively for the South African applicants whose names had been put forward along with that of the gentleman recommended. So far as the city council is concerned the incident now apparently ends, but it is more than likely that the last has not been heard of the matter in medical circles, this being only one of several instances where local authorities have endeavoured to import men for positions which, it is asserted, can be filled just as efficiently by local candidates. If and when the whole matter crops up for discussion again, be it in medical or lay circles, it is sincerely to be hoped that views will be expressed dispassionately, bearing in mind that in the making of any public appointment efficiency should always be the deciding factor, other things being equal.

India.

PUBLIC HEALTH IN CEYLON.

THE estimated population of Ceylon in 1925 was 5,009,502, of whom 10,212 were Europeans. The birth rate was 38.58 per 1,000, and the death rate 23.46. The infantile mortality in the thirty-three principal towns of the island was 216 per 1,000 births, as compared with 235 in the previous year; this improvement is attributed by Dr. J. F. E. Bridger, Principal Civil Medical Officer and Inspector-General of Hospitals in the island, to the activities of child welfare associations, the establishment of crèches in the principal towns and on the estates, and the teaching of mothercraft in the training schools for pupil teachers. In his annual report for 1925 on the health and sanitary condition of Ceylon Dr. Bridger states that 1,063 deaths were caused by malaria, as compared with 1,388 in the previous year. Antimalarial campaigns were in progress in several places, and the number of cases treated in hospitals and dispensaries decreased markedly during 1924 and 1925. A rapid survey of filariasis in the southern province was made at the end of 1925, and the distribution of infection was found to be very patchy, as had been previously reported in 1912 by Manson-Bahr. The campaign against ankylostomiasis is being continued jointly by the Government of Ceylon and the International Health Board of the Rockefeller Foundation. The survey of the island, commenced in 1924, has been completed, and mass treatment given, carbon tetrachloride in magnesium sulphate solution being employed for adults and oil of chenopodium in castor oil for children. In some cases the two remedies were combined, and proved very efficient in dealing with both hookworm and ascarine infections. An intensified scheme of treatment throughout the island is thought to be advisable, and active educational work by lantern lectures, distribution of literature, and meetings is suggested. Slow progress is being made in improving sanitation. The two leper asylums in Ceylon treated about 700 cases during the year. The number of patients with framboesia admitted to hospital fell from 6,149 in 1924 to 4,897 in 1925, as the result of intensive campaigns by eight itinerating medical officers, who treated 13,075 patients. During the early part of 1925 a training class in health and sanitation was held for police, headmen, and others, and the public health section organized in connexion with a horticultural exhibition was very well attended.

MEDICAL RESEARCH IN INDIA.

The fourth annual conference of medical research in India was held at the School of Tropical Medicine in Calcutta during December, 1926, and occupied four days. The president, Major-General T. H. Symons, C.S.I., Director-General of the Indian Medical Service, in opening the conference, reviewed the position of medical research in India, and explained how enlargement of the programme had become possible as a result of the full restoration of the Government grant. It was proposed, he said, to name the new experimental station at Karnal the Ross Experimental Station for malaria. A discussion afterwards took place on the steps to be taken to establish a permanent and efficient organization for the study and control of malaria. The lines laid down by previous conferences have already been adopted to a considerable extent by the Central Government, and the hope was expressed that provincial Governments would co-operate more closely in the future in some general scheme for India. Subcommittees dealt with improvements in the co-ordinated research work in connexion with plague and cholera, and mention was made of the new bili-vaccine method of treatment. It was stated, however, that in some parts of India the benefits of inoculation were becoming so much appreciated that a vaccine given by the mouth would probably be less popular. Reports of the work of the Kala-azar Commission and of the inquiry at the Calcutta School of Tropical Medicine were discussed, and satisfaction was expressed at the extent and value of the various investigations. Other subjects considered by the conference were tuberculosis, which is one of the more important causes of mortality in India; the investigation of sprue at the Haffkine Institute, Bombay; leprosy; the study of beri-beri in Burma and South India; and the almost complete survey of hookworm throughout India.

INDIAN SANITARY REPORT.

The annual report of the Public Health Commissioner with the Government of India for 1924 has recently been published in two volumes. The delay in its appearance is attributed to the late receipt of the Bengal provincial reports, when the Public Health Commissioner was a delegate in Europe at the International Sanitary Conference, Paris. The report has been

increased from eight to nine sections, and is somewhat differently arranged from that for the preceding year (1923). The sections dealing with the army, British and Indian, have been removed from the beginning to the end, and the report now begins with the section on the state of public health in British India. The new section, which is entitled "Medical intelligence and international health, including ports," is placed second.

In 1924 the birth rate fell from 35.06 to 34.45 per 1,000; the death rate rose from 25 to 28.49 per 1,000. Most provinces showed a birth rate higher than the quinquennial mean. Deaths numbered 842,235, more than in the preceding year, but the death rate also was below the quinquennial mean of 29.20. Registration of deaths is stated to be very imperfect. This probably applies more to the causes of deaths than to the actual number. But death registration is likely to remain imperfect until it becomes impossible, or at least difficult, to dispose of an unregistered dead body. The number of deaths really due to malaria is stated to be probably not more than one-third of the number registered under this heading. An interesting malaria map of India, compiled at the Central Malarial Bureau, Kasauli, is given in Section II. Tuberculosis is generally asserted to be on the increase in India, but the report states that there is no definite proof of this. There are eighteen tuberculosis sanatoriums in India, of which seven are in the Bombay Presidency. The provinces of Bihar and Burma have none, but Bihar has special wards for the disease in eight headquarters dispensaries. Cholera showed renewed activity, chiefly in the Gangetic plain, after two years' comparative quiescence; 1923 has shown the lowest mortality for thirty years. Plague mortality also was higher than for five years past, chiefly due to an epidemic in the Punjab, with 251,261 deaths, nearly five times the mortality of 1923. The United Provinces, Madras, Bombay, and Bihar showed a decrease. Rabies caused 2,044 deaths. There are four special institutes for the treatment of rabies—at Kasauli, Coonoor, Shillong, and Rangoon—besides which special arrangements for the treatment of the disease are in force at Calcutta, Bombay, and Lahore. Over 20,000 deaths were caused by wild animals. Snakebite accounts for 19,867 deaths, while all other animals caused only 2,587 deaths, tigers (1,174), wolves (419), and leopards (406) being the chief culprits. The total number of vaccinations rose by nearly a million to over ten millions, almost the whole increase being under revaccinations. Seven special research institutes were at work in 1923—Kasauli (two), Bombay, Madras, Coonoor, Shillong, and Rangoon. An eighth is mentioned in 1924, in Mysore State, but its chief work seems to be water analysis. A list is given (pp. 106-109) of special researches undertaken during the year; and near the end (pp. xxxvi-xlvii) a list of papers published in the *Indian Journal of Medical Research*. The number of medical institutions—that is, civil hospitals and dispensaries—increased from 3,634 to 3,669; the number of patients from 38,059,386 to 39,381,032; and the number of operations from 1,194,664 to 1,278,036. These figures give some idea of the scale on which charitable medical work is done in India. There were twenty-two mental hospitals, as lunatic asylums are now called, with a daily average of 7,605 inmates, including 738 sick. About one-third (2,501) were criminal lunatics. The total number is probably about 1 per cent. of the number of insane persons in India. There are seven medical colleges, one of which, the Lady Hardinge Medical College at Delhi, with 108 students, trains women only. The number of students in the others varies from 1,155 at Calcutta to 269 at Lucknow. There are also twenty-two vernacular medical schools, of which four are in Bengal, seven in Madras, and three in Bombay; four train women students only. The average jail population was 126,664. Both sick rate and death rate of prisoners show a slight decrease. There were no epidemics in jails during the year. British troops show a slight increase in admission rate, daily sick rate, and death rate. The death rate of 4.20 per 1,000, however, was lower than that of any previous year except two—1913 and 1923. For venereal disease the admission rate decreased to 58.9 per 1,000. That for Indian troops was only 22.3. For Indian troops the admission rate (423.1 per 1,000) and the average sick rate (18.05 per 1,000) were both the lowest on record. The death rate (5.73) and invaliding rate (12.8) were below those for 1923, but still in excess of the 1910-14 quinquennial period. One-third of the sickness among Indian troops was due to malaria. The report states that "the financial outlay on the Indian station hospital scheme is being justified from year to year."

Correspondence.

THE THYROID AND MANGANESE TREATMENT IN ACUTE PNEUMONIA.

SIR,—Whatever be the value of this treatment (in pneumonia or other conditions), it is not of importance that strings of mucus, "even mucous casts of the bowel," be afterwards passed. The rectum and colon of many healthy, if costive, people would thus react.

I am not informed on Dr. Nott's treatment of pneumonia by thyroid and manganese (this being the subject of the paper by Dr. Roche in your issue of March 12th), but reflect that many treatments, sometimes any treatment, produce excellent results. Unfortunately, at times, all fail—in pneumonia. And the cases quoted by Dr. Roche in support of Dr. Nott's treatment are not impressive, and, so far as the charts go, do not convey the idea of serious illness, but of a favourable condition running a natural course towards recovery, which would have been achieved by any form of simple treatment. In no case did the temperature reach 104°, nor the respiration rate 40, nor the pulse exceed 130, according to the charts. In fact, I do not understand the charts. I have yet to see an infant of 15 months, with double bronchopneumonia, and weakened by measles, with a respiration rate of only 36 and a pulse of only 130. This was on the first day of treatment, I understand, and after twenty-four hours there was no change in pulse or respiration, and the temperature had not fallen one degree. Case III is even more extraordinary in these respects. Whatever the clinical condition was, the facts as disclosed by the charts, so far as they go, suggest mild cases, running a favourable course.

While indebted to Dr. Roche for his communication, I feel, as no doubt others do, that the greatest care must be exercised in deducing the effect of the treatment in a series of cases so simple (by the charts) as these were. I am sure Dr. Roche will agree, and welcome the criticism I offer.—I am, etc.,

Glasgow, W.2, March 13th. R. O. ADAMSON.

TUBERCULIN IN THE PROPHYLAXIS AND TREATMENT OF TUBERCULOSIS.

SIR,—The article which appeared in the JOURNAL of February 19th (p. 340), headed "Tuberculin in the prophylaxis and treatment of tuberculosis," especially that first part of it which deals with prophylaxis, is, in my opinion, one of the most important and stimulating publications which I have read in recent years.

I will quote two passages which are worthy of the most serious consideration, not only in regard to the stamping out of tuberculosis, but in the removal possibly of all other widespread infectious diseases also.

The first is as follows: "The control of an infectious disease may be attempted in two ways—first, by exterminating the germ which causes the infection; secondly, by immunizing, or raising the resistance of, potential sufferers from the disease." And the second, dealing with the modern procedure in regard to tuberculosis, states: "The object of all these measures is to prevent the dissemination of the tubercle bacillus. They have had some success, but it is very far from being complete; so widespread is the disease that many doubt if it ever can be; and not a few experts in the disease hold that if the measures were successful the result would be a community intensely susceptible to chance introduction of infection. If they are correct it would follow that the only way to check the ravages of tuberculosis must be by some form of immunization."[2]

There is nothing absolutely new in either of these statements, but yet the subject is put in such a clear and concise form that it would be difficult to overestimate the importance of the question raised. Hitherto, I am afraid, a good many of us have been unable to see the wood for the trees, but here we now get a clear bird's-eye view of the whole forest.

The question arises whether we have not been devoting far too much attention to exterminating the tubercle bacillus, to the neglect of the most efficient method of combating the disease—namely, by developing in the community a high degree of immunity. This latter should now be our war-cry, and we should not rest until the immunity developed is so great that the tubercle bacillus, which is now a pathogenic organism of high virulence, has been rendered non-pathogenic and harmless.

Syphilis was a deadly scourge in Europe during the Middle Ages, and is still a serious disease in this country. Along the littoral of the Mediterranean, however, especially on the African coast (where I understand the infection is found in upwards of 80 per cent., if not more, of the population), the disease has become so mild that it is not now taken seriously, and late manifestations are quite rare.

Again, trypanosomiasis, which is so deadly to the domestic cattle in certain parts of Africa, produces no symptoms in the wild cattle inhabiting the same areas, although they are equally infected. This is not due to any weakening or loss of virulence on the part of the virus, as when the same has been transferred to a susceptible subject he develops the disease in all its strength, but is the result of prolonged immunization extending over several generations.

Your valuable space will only allow me two further illustrations, but they will suffice. Malaria, which is severe and often deadly amongst white people, is almost non-pathogenic in the coloured populations of the malarial countries; and small-pox, which was the terror of England in the middle of the eighteenth century, is now, after over one hundred years of vaccination, showing itself as quite a mild disease, as witness the recent outbreaks in the North of England, where even in the unvaccinated it is to a large extent benign.

I am not suggesting that we should abandon our efforts to find a means of arresting the disease in persons already suffering from tuberculosis; far from it. I think we should persist for the sake of those who will suffer until the immunity has been developed; but I am most strongly of the opinion that the time is now ripe for a great campaign of preventive medicine, the ultimate objective of which is the changing of the tubercle bacillus from a highly pathogenic into a non-pathogenic organism. The road is clearly defined for us, and a beginning has already been made by Calmette and others.

As this question is of transcendental importance, it behoves all States which have the interests of their people at heart to begin forthwith and establish institutions for the study of immunity.

Team work and concerted action should be so developed that the subject could be tackled from every possible direction, and all the different institutions in all the different States should work together, arranging between themselves as to the distribution of the work. Generations may be required before the objective is fully achieved, but even a hundred or more years would be well occupied if at the end tuberculosis could be considered a thing of the past, and in the meantime a steady improvement could be looked for.—I am, etc.,

Corbally, Limerick, March 13th. E. G. FENTON.

MALIGNANT DISEASE OF THE THROAT.

SIR,—As one to whom it has fallen to have to deal with a large number of cases of malignant disease of the throat, I write to impress upon general practitioners, to whom these present themselves in the first instance, the great, the vital importance of the recognition of the earliest stages of the disease when removal by one or other method is distinctly hopeful. I am impelled to this by the case of a patient whom I have seen to-day: a man with a growth in his pharynx, suitable for removal by surgical diathermy; but he has a large mass of glands in the neck so extensive that even a large dissection could not eradicate them. This is by no means an isolated case. One hesitates to use strong language, but in view of the seriousness of the question I feel justified in saying that the delay in arriving at, or in obtaining by reference to those who are competent to give, a definite and early diagnosis in patients suffering from symptoms which may be due to malignant disease of the throat is inexcusable nowadays, when for a number of years special instruction in diseases of the throat has been a part of the medical curriculum.—I am, etc.,

Glasgow, Feb. 28th. W. S. SYME.

PHARYNGEAL DIVERTICULA.

SIR,—In the JOURNAL of January 8th (p. 79) Dr. William Hill questioned the grounds on which, during the discussion on his paper on "Pharyngeal diverticula" at the Annual Meeting of the British Medical Association at Nottingham last year (BRITISH MEDICAL JOURNAL, December 18th, 1926, p. 1163 et seq.), I objected to the case published by Sir Rickman Godlee and Mr. Bucknall in 1901 being described as a pharyngeal diverticulum.

I replied to his criticism in the issue of January 15th, and stated the grounds on which, from the clinical and anatomical standpoint, the tumour in this case could only be looked upon as a laryngeal air sac, and that I was prepared to admit the pharyngeal origin of the sac if the microscopic section could be traced, and if definite muco-salivary glands were, as stated, proved to be present. I had not, at the time, considered the question from an embryological point of view.

I now find that the microscopic slide to which I referred has unfortunately been misplaced among the many thousand others at University College Hospital. There is a note, however, by Mr. Lawrence at the museum of his having received the specimen, which is entered as a "pharyngeal or laryngeal sacculus," the latter being deleted; it is therefore evident that the possibility of its being an aerocele was considered at the time.

I was on the point of supplying further proof of the laryngeal origin of this tumour, from an embryological point of view—namely, the relationship of the carotid vessels and superior laryngeal nerve to the canal of the sac—when an unexpected meeting with Sir Arthur Keith, on January 17th, brought to light the following remarkable and somewhat dramatic story, which I think it will be admitted settles the present discussion in my favour. The story runs that on the Sunday following the publication of Godlee and Bucknall's paper in the *Lancet* (1901) he (Sir Arthur Keith) wrote a letter to Godlee, and pointed out that the description and anatomical relationship of the tumour left no doubt whatever that it was a laryngeal air sac; to which Godlee replied, accepting this opinion, and admitting that he was wrong in describing it as pharyngeal. Unfortunately Godlee does not appear to have taken any steps to correct his mistake. If this had been done, and Keith's opinion recorded, the present controversial, but friendly, discussion would not have arisen.

The reconsideration of this case has led me to examine further Dr. William Hill's recent classification of pharyngeal diverticula, and especially the group which he describes as "Congenital lateral pharyngeal diverticular sinuses and aeroceles of abnormal branchial cleft origin," or, again, as "Congenital lateral post-faucial diverticula (synonyms: Aeroceles; branchial diverticula)," usually opening by a mouth in the region of the palato-pharyngeal fold just behind the tonsil.

Dr. Hill, in his paper, says, "it is only very exceptionally, however, that a sinus passing into the neck from an internal pharyngeal orifice expands into an aerocele," and refers to Godlee and Bucknall as having published such a case (the case discussed above), and that they also mentioned a number of recorded cases in which an internally opening sinus had developed into a well marked diverticular aerocele, which presented as an obvious air-filled swelling in the neck. He also draws attention to two of the cases referred to by Godlee and Bucknall as coming under the

same group—namely, one recorded by Watson of Edinburgh in 1875, and another by Wheeler of Dublin in 1886.

The case recorded by Watson as a "remarkable pharyngeal diverticulum" cannot be described and accepted as a cervical acrocele, for there is undoubted evidence that it was a branchial cleft sinus with a dilated saccular or cystic extremity. It originated behind the position of the thyro-hyoid membrane, and such a diverticulum never contains air (Keith). It corresponded in position to the embryonic cervical sinus. Watson himself suggested the possibility that it was a visceral cleft abnormality.

Sir Arthur Keith states that every air-containing sac in the neck which perforates the thyro-hyoid membrane has only one origin, and that is the sacculus laryngis, and that no cervical air sac ever originated in the pharynx; they are all laryngeal and originate from the sacculus laryngis. He further says he has never met with an example, or any evidence, of an air-containing sac in the neck having any other origin, and that there is no such thing as an air-containing pharyngeal diverticulum of developmental origin.

Wheeler described his case as a "pharyngocele with dilatation of the pharynx," and the tumour in the neck as "a sort of aneurysma herniosa" of the pharynx. He expressed his opinion that the primary cause of the tumour was the violent exertion of the voice (the patient was a military man with a stentorian voice, who prided himself on the fact that he could drill an entire brigade by his own word of command), which first led to dilatation of the pharynx, and then some violent effort produced a slight protrusion of the mucous membrane, which became further stretched by food and drink getting into it.

Wheeler mentioned that the internal orifice of the sac, which opened precisely upon the site of the sinus pyriformis, was so large that a complete view of the larynx could be seen through it—that is, the epiglottis, ary-epiglottic folds, vocal cords, etc. He also described the orifice as being entirely bounded by the following muscles: the superior constrictor above, the middle constrictor below, the palato-pharyngeus anteriorly, and the stylo-pharyngeus posteriorly. These boundaries, therefore, place the orifice above the great cornua of the hyoid bone. Dr. Hill in his paper refers to the stalk or canal of the tumour as having been traced upwards between the two carotids. No statement of this kind was made by Wheeler in his original publication, and it is evident that this description belongs to the case which Watson recorded, and which confirms the fact that his case was a branchial cleft diverticulum.

In his classification Dr. Hill places Wheeler's case under the group of congenital lateral post-faucial diverticular acroceles of embryonic branchial cleft origin. In my opinion, and I am supported by Mr. Lawrence, the tumour in this case should be described as a "lateral pharyngeal pressure diverticulum or pulsion pouch."

The case therefore contradicts the general statement, accepted and repeated by Dr. Hill and others, that the mouth of a pharyngeal pouch is *always* in the deep pharynx, and invariably situated posteriorly and mesially at the line of junction of the upper oblique and lower transverse fibres of the inferior constrictor muscle, as is the case in those commonly met with and described.

The late Professor S. G. Shattock[1] stated in 1923 that he did not agree that these pouches always arose in the middle line. He knew of one specimen in which "the situation of a lateral pouch was immediately behind the posterior border of the thyroid ala."

It is obvious, therefore, from the points enumerated and the opinion expressed, that the three cases quoted by Dr. Hill cannot be described as cervical acroceles, and that the term "acrocele" should be deleted from the group of congenital lateral pharyngeal diverticular sinuses of abnormal cleft origin; and further, that all diverticula which pass through the thyro-hyoid membrane contain only air and no food, and are outgrowths of the sacculus laryngis.—I am, etc.,

London, W., March 1st. IRWIN MOORE.

*** The correspondence on this subject in our columns may now be considered at an end.

PATENTED RESEARCH.

SIR,—Your editorial comments (March 12th, p. 479) upon the taking out of a patent by the Dicks are timely, and I should like to elaborate the points, having had some small experience of patents—non-medical, of course.

It is quite possible to patent something which is of no practical value, but which may later prove to be a necessary step in the manufacture of something of great practical utility; in such a case the owner of the earlier patent can "hold up" the whole business until he is bought out or given a share of the royalties. Wireless telephony is the most prominent example in recent times.

I hope shortly to publish further results of treatment with residual vaccines. This type of vaccine would furnish an example of the state of affairs that would arise if I had attempted to patent the process of preparation, and certain other workers had also patented their original work. The oxidation process would be the property of Professor H. R. Dean, the washing would belong to Dr. David Thomson—with the proviso that Michaelis might lodge an objection on the grounds of prior use of acid agglutination and precipitation.

It should not be forgotten, however, that one cannot in this country obtain a patent for the use of a remedy to relieve human suffering; the law would only grant protection to some special method of preparing the remedy, and it is very doubtful if the utilization of the special streptococcus of scarlet fever is patentable at all. It is certain that the preparation of a serum for the cure of scarlet fever is not patentable.

The first of these patented remedies was insulin, I believe, and the Canadian patent was presented with a great flourish of trumpets to the Medical Research Council; it would be interesting to know if the Council applied for an English patent under the International Convention, and if one was granted. If the English patent exists it can only refer to the process of manufacture.

It appears to me that even if this system of protecting one's work becomes common it will not be of much real use to the owners of the patents, because the inability to prevent unauthorized use for human treatment will enable anybody to drive a coach and four through most of the patents.

At the same time, the probable angle at which the Dicks look at the matter can be surmised. They see great commercial concerns selling the remedy to the profession, and the public paying huge sums in fees for its use, whilst they get nothing out of it. The public professes a great admiration for the noble work of our profession, but regards the question of fees from a strictly business standpoint.

The only section of the community that has any moral justification for raising an outcry against the patenting of medical research is our own profession, particularly pathologists and other research workers. The lay public—and Big Business in particular—would have no just grounds for complaint.—I am, etc.,

Manchester, March 12th. C. E. JENKINS.

SYSTEMIC TREATMENT OF CANCER.

SIR,—With reference to the remarkable results stated by Dr. Coley in his letter, published in your issue of January 29th (p. 211), I have been hoping that there would have been letters from surgeons in charge of cancer wards, and others, relating their experience with Coley's method of treatment of cancer by means of the mixed toxins of erysipelas and *Bacillus prodigiosus*. I would especially call attention to the following paragraph in Dr. Coley's letter:

> "In a recent follow-up of ninety-three cases of inoperable sarcoma treated with the toxins alone I find sixteen patients have remained alive and well from eight to thirty-three years, and twelve from ten to thirty-three years."

Since inoperable sarcoma means (except in rare instances) inevitable death, these results are most striking.

It is important that we medical officers of health, who are expected to assist in the launching of cancer campaigns, should know what is being done in this country with regard to this form of treatment, which Dr. Coley mentions has also been used successfully in a number of inoperable cases

of carcinoma. It must be remembered that the majority of cancer deaths are due to internal cancers which cannot be, or are not, diagnosed sufficiently early to permit of successful operation.

I would suggest that Dr. Coley should publish in detail the technique of his methods, so that the information may be available for all practitioners who have cases suitable for his method of treatment, the dangers of which, he points out, are practically *nil*.—I am, etc.,

County Offices, Dorchester, March 1st. J. E. ROBINSON.

*** Dr. Coley's treatment of inoperable sarcoma by the injection of a mixed suspension of *Streptococcus erysipelas* and *B. prodigiosus* aroused considerable interest some time back. He stated his views fully to the Section of Surgery of the Royal Society of Medicine in July, 1909; a very good and full abstract of his paper appeared at that time in our columns (JOURNAL, 1909, vol. ii, p. 144), and the complete text was published in the *Proceedings of the Royal Society of Medicine*, 1910, vol. iii, Part III. Dr. Coley gave details of his technique and its successful employment in fifty-two cases of sarcoma. He stated that the changes in the tumour were the same whether the bacterial toxins were injected directly into it or into remote parts of the body, thus indicating that their action is systemic rather than local. He suggested that this treatment was also likely to be useful as a prophylactic against the recurrence of carcinoma after operation, and added that he had obtained some little evidence of its efficacy in dealing with carcinomatous growths. In his recent letter, to which Dr. Robinson refers, Dr. Coley mentioned that he has a book in preparation which will contain a complete report of his results to date, including a number of cases of carcinoma in which the tumours entirely disappeared as the result of this treatment.

WIRELESS MEDICAL CONSULTATIONS AT SEA.

SIR,—I enclose copy of suggestions I recently sent to the Board of Trade (Mercantile Marine Department) by request.

1. All medicines for internal use to be carried in the form of concentrated stock mixtures (two or three of which to contain opium, etc., within the limits of the Dangerous Drugs Acts), pills, and tablets. This would prevent misuse of sedatives, avoid difficult dispensing, and be more effective. I consider that eight or ten formulae for mixtures, eight or ten for tablets, and six or eight for pills would be ample, and, of course, salts and quinine.

2. Chief stewards should have the first aid certificate, and have two or three lectures on simple nursing and on the medicines carried. It falls to their lot to look after any sick.

3. The first aid course should be more like the navy one than that of the St. John Ambulance Association.

4. A more frequent inspection by a Board of Trade medical officer. I have never heard of one.

Dr. Lillingston's letter in your last issue shows the chaos the subject is in.—I am, etc.,

Brighouse, March 14th. F. F. BOND.

BREATHING EXERCISES WITH MOVING ARMS.

SIR,—A sentence in Surgeon Commander Horace Hill's paper (March 5th, p. 422) calls for comment. "Neither, when the arms are raised, can any pull occur on the ribs to elevate them, any muscles tending to oppose the raising of the arms being elongated and their tone inhibited (Sherrington's proprioceptive reflex and reciprocal action of antagonistic muscles)."

But when one sits in a chair and palpates the tendons of the hamstring muscles, one finds that on extending the leg on the thigh, with the elongation of the hamstrings, the tension of their tendons increases: thus, the tension of the hamstrings must increase, so that they are not inhibited. Again, if with the elbow flexed and the arm so held that the elbow points upwards (to put the effect of gravity on the biceps and of torsion on the joint out of court), the tendon of the biceps of the arm is palpated by grasping it between a finger and thumb in the anticubital fossa, one finds that on extending the forearm on the arm the tension of the biceps tendon increases in spite of the fact that the muscle is elongated. And if one lies on the back and palpates the pectoralis major muscle by grasping it in the anterior fold of the axilla, with the arm in a position of adduction, and then moves the arm into abduction, it is found that with and during the movement, as the *pectoralis major is being* extended (that is, elongated) its tone—its tension—that is, its state of contraction, progressively increases.

How, then, can it be said that raising the arms does not elevate the ribs, causing, or tending to cause, an expansion of the chest, and, if the glottis and diaphragm permit, an inspiration? We know very well that such movements do have such effect, and for this reason are commonly employed for artificial respiration. How do they cause inspiration, if not by the effect of the movement on the tone—on the tension—of the pectorales?

Many other instances of this "action" of muscles "opposing" a movement exist. Thus, on inspiration (with fixed thorax), with the descent of the diaphragm, the belly wall bulges and the recti abdominis become harder (Keith) (that is, more contracted). As the erect individual stoops, the erector spinae become longer and yet are more contracted (Zuckerkandl) (as they obviously must be—for they have to do greater work). As the pelvic floor descends during straining (for example, during defaecation and parturition) the muscle fibres of the levator ani, though they become longer, become more contracted (Halban and Tandler). So also we see that during pregnancy the flank muscles of the belly wall become so elongated and so resist the elongation that not only they but their aponeuroses suffer, producing a muscle weakness and a separation of the recti (regression). If the flank muscles were simply "inhibited" and simply elongated, no separation of the recti would occur.

Can, then, the doctrine of the reciprocal innervation of antagonistic muscles stand? Or are the experiments on which this conception is based (at least those adduced in that most interesting book *The Integrative Action of the Nervous System*) open to another interpretation? Do the phenomena I have mentioned throw light on Thomsen's disease, and on the difficulty of movement experienced by individuals who are "muscle bound"? Is not the muscular state of an individual poisoned by strychnine but an exaggerated picture of the normal? Or is it, as has been suggested, an exception? Perhaps, after all, the "inhibition" (the dying away of the tonic contraction) of a muscle or of a muscle group opposing a movement is the exception—the active participation of opposing muscles in a movement being an absolute necessity for "co-ordinated," that is, precise movement. (Compare tabes dorsalis.)—I am, etc.,

Rugby, March 6th. R. H. PARAMORE, F.R.C.S.Eng.

RESISTANCE TO QUININE IN MALARIA.

SIR,—Sir Humphry Rolleston's reference to the extremely resistant character of malaria to quinine treatment during the war in the Macedonian area (January 15th, p. 89) raises certain questions.

The past malarial season in the Punjab, India, has been a very bad one, and has provided more material for discussion than could be satisfactorily dealt with in full scientific and statistical manner, and I am therefore unable to give figures in support of my statements. Cases diagnosed malaria (almost invariably benign tertian or malignant tertian, or both) as a result of microscopic examination were immediately treated by quinine sulphate, and in the large majority this led to the condition being brought under control. In practically all cases where the pyrexia did not yield to this treatment, urinary examination revealed that no quinine was being excreted by this channel, and presumably, therefore, was not being absorbed. Substitution of quinine hydrochloride, or the bihydrochloride, resulted invariably in a fall of the temperature to normal, and in the appearance of quinine in the urine.

This suggests to me that it was not a question of the malarial parasites being resistant to quinine in the war area in question, but merely lack of absorption of quinine; medical officers in the area were too overworked to study each individual case after being satisfied that the condition

was malarial; and often lacked previous experience of tropical diseases.

The time available for the study of this question was not very great, but I raise the point in the hope that others with similar experience may investigate it.—I am, etc.,

February 11th. I.M.S.

THE AFTER-TREATMENT OF MASTOID OPERATIONS.

SIR,—In your issue of February 26th (p. 375) Mr. A. J. Wright has drawn attention to the advantages of ambrine, or the *British Pharmaceutical Codex* paraffin No. 7, as a dressing for the radical mastoid cavity. Originally suggested by Daure in 1917, the method has received the strong support of Liebault, who published results in the *Revue de Laryngologie*, vol. 45, No. 7, 1924. Probably this is the reference which Mr. Wright desires. Liebault does not commence the ambrine treatment until the sixth or eighth day after operation. He renews the dressing every second day, and states that within a fortnight the cavity is almost dry and lined with epidermis. Although my personal experience of the method is small, the results have been most encouraging.

The "simple" or Schwartze operation has been robbed of its terrors by immediate suture following the use of bipp paste. May we not hope that a similar revolution in regard to the "radical" operation may be achieved when otologists recognize the value of the paraffin treatment?—I am, etc.,

Edinburgh, March 7th. DOUGLAS GUTHRIE.

INFLUENZA AND ALBUMINURIA OF PREGNANCY.

SIR,—There must, I think, be some more than casual relationship between influenza and albuminuria of pregnancy, even if it does not amount to cause and effect, which I feel is not improbable. I have had a number of cases of albuminuria of pregnancy passing through my hands during the last few weeks whilst the epidemic of influenza has been with us, and on looking through the hospital records I see the same was true during the epidemic of 1919. Then I put it down to a different cause, but I think I was wrong in view of my present experience. At that time I assumed it was the result of pregnant women getting back to a more generous diet than had been possible during the war.

I should be interested to know if the experience of others has been similar to my own during this and the previous epidemic, and why it is that the pregnant woman only is affected in this way.—I am, etc.,

Ipswich, March 10th. JOHN GUTCH, M.D.

PUERPERAL SEPSIS.

SIR,—I am obliged to Dr. Oxley for drawing my attention to a seeming misinterpretation of the table given in the East End Lying-in Home for the year 1925. By sepsis I mean puerperal sepsis. My figures were on that basis for both this home and the Glasgow Maternity. To satisfy Dr. Oxley, let me now give the figures for the relative *deaths* from sepsis. In 1925 one patient (ill before admission) died from sepsis; outdoor none. In Glasgow the deaths were: indoor 26, outdoor 8. In forty-one years in London there have been 3 deaths from sepsis indoor, against 866 in Glasgow; and not one death outdoor, against 328 here.

I agree we are all striving to reach the ideal of no sepsis, but Dr. Fairbairn quoted this home as an example of what could be done by the general practitioner, and I ask him how his figures compare with it, and I ask Professor Kerr the same. Is this unfair?—I am, etc.,

Dennistoun, March 12th. JAMES COOK, M.B.

DR. ARCHIBALD CAMERON.

SIR,—As must often happen in the case of the vagabond members of the Association, my weekly copy of the JOURNAL often follows an erratic course before it reaches me—for example, the issue of December 4th, 1926, has only come into my hands to-day; hence this delay in writing.

On page 1056 of that issue, under the heading "Medical Criminals," appears a report of "an address on some well-known medical criminals," given by Dr. L. A. Parry. Now, Sir, I do not accuse Dr. Parry of deliberate malice; but am wishful to enter my protest against the inclusion of Dr. Cameron in the same category with poisoners, with other kinds of murderers, and with mob leaders and burglars.

Archibald Cameron and all of his brothers, the eldest of whom was chief of his clan, were royalists: no doubt the members of the Hanoverian faction professed to regard them as traitors; but had the royal arms been fortunate instead of unfortunate in 1745, the King would have come back to his own again and the Hanoverians would have been traitors before the law. It is notorious that Dr. Cameron freely gave his services to the wounded of both sides and that many Hanoverians gave their cordial testimony to his humanity. After he had escaped to France in 1746 (he was a member of the prince's party, including Lochiel himself and the father of Napoleon's famous marshal, MacDonald, who escaped from the West Highlands by the French brig) he, carrying his life in his hands, returned to Scotland on three occasions on his royal master's business, the father of the latter, James VIII and III, being still alive. On the third of those occasions he was sold by the despicable Puckle the spy (young Glengarry, from whom, however, the present house of Glengarry is not descended); he was taken south and executed in London on June 8th, 1753; he remained loyal to the end; and even the bitter sort of the Hanoverians themselves regarded his execution as a judicial murder. Wherever pristine loyalty is cherished he is known as the last of the Jacobite martyrs. His name is not one to be mentioned with names of poisoners, etc.—I am, etc.,

January 27th. NOMADIC DOCTOR.

*** On the proverbial saying "Treason never prospers" somebody a few centuries ago made the couplet:

> Treason doth never prosper. What's the reason?
> If it prosper none dare call it treason.

This seems to put our nomadic correspondent's argument pithily and wittily. Amid the fierce passions of the eighteenth century the prudent man chose his party with care, but in justice to Dr. Parry we must recall that he was careful to put those accused of high treason in a class by themselves. We have shown this letter to Dr. Parry, who asks us to offer his sincere apologies to the writer. Dr. Parry adds: "Dr. Cameron should not be called a famous criminal; I fully recognize my mistake. The proper title of my lecture should have been 'Some famous medical trials,' and this is the name under which I am shortly publishing a book, an extension of my lecture."

THE DEVELOPMENT OF VAGINAL OPERATIONS FOR GENITAL PROLAPSE.

SIR,—I submit the following brief reply to Dr. R. A. Paramore's letter in your issue of December 25th, 1926 (p. 1241).

1. The primary or main supports of the uterus are the cardinal ligaments. This view is borne out, first, by the late Arthur Nyulasy's successful operation of looping or shortening these ligaments, and thereby overcoming uterine prolapse; secondly, by the fact that the perineum may be lacerated right into the rectum without any uterine prolapse whatever occurring; thirdly, by the fact that, in an ordinary vaginal hysterectomy, the uterus cannot be fully brought down until the cardinal ligaments (in the base of the broad ligaments) have been divided; fourthly, by the emphatic opinion of the eminent anatomist Professor A. F. Dixon on "The supports of the uterus," as expressed in the BRITISH MEDICAL JOURNAL of March 29th, 1919 (p. 378).

2. The secondary support of the uterus is the pelvic diaphragm, which prevents undue stretching (that is, strain) of the cardinal ligaments as the result of intra-abdominal pressure; so that, in this regard, the function of the pelvic diaphragm is merely subsidiary to that of the cardinal ligaments.—I am, etc.,

Melbourne, Feb. 5th. FRANK A. NYULASY, M.D.

PRACTITIONERS OF PATHOLOGY.

SIR,—The British Pathologists Association was formed at a meeting held in London on January 7th last, for the purpose of developing the application of pathology in relation to medicine, and of protecting the interests of those engaged in its study and practice. Membership is open to all registered medical practitioners engaged in the study and practice of pathology.

It is, in the opinion of the council of the association, very necessary that there should be in existence a schedule of minimal fees payable for pathological investigations for persons insured under the National Health Insurance Acts. In the absence of such a schedule there is bound to be competition for this work, with consequent fee-cutting and inefficiency.

The council of the association has in hand the drafting of a schedule of fees for the various classes of laboratory investigations in general use in clinical medicine. The fees in this schedule have been worked out on the basis of the cost per pair of hands per hour employed in a pathological laboratory under the direction of one of the members of the association, the costs of which have been accurately controlled over a period of years. The fees indicated may be regarded as the minima which can be expected to give a reasonable financial return when the procedures are performed in a laboratory subsidized from no outside source.

Copies of this schedule will be sent on request to all members of the association, for comment or suggested amendment.

The British Pathologists Association is working in the very closest touch with the British Medical Association, from which it has received invaluable help. The schedule of fees for pathological investigations is to be submitted to the Insurance Acts Committee of the British Medical Association at an early date, at a meeting at which the whole question of provision of a pathological service for panel patients will come under discussion.

It is proposed to submit this schedule to the Ministry of Health and to urge its adoption for pathological work performed for insured persons under any arrangements made either by the Ministry or by individual National Health Insurance Committees.

In approaching the Ministry of Health the British Pathologists Association wishes to be able to speak as representing the body of practising pathologists in this country. Practising pathologists not already members of the association are therefore urged to become so. The annual subscription is £1 1s., which includes entrance fee. Medical practitioners desiring to join the association should communicate with one of the members of the council, which is constituted as follows:

Dr. C. Powell White (President), Victoria University, Manchester; Dr. J. G. Greenfield, National Hospital, Queen Square, London, W.C.1; Dr. S. C. Dyke, Wolverhampton and Staffordshire Hospital, [illegible], 16, St. John Street, Manchester; [illegible]on and East Cornwall Hospital, [illegible]neral Hospital, Bristol; Dr. A. G. [illegible] Hospital, Eastbourne; Dr. A. F. [illegible]wansea; Dr. W. Grace, Royal Infi[illegible]lly, Royal Devon and Exeter Hospital, Exeter.

—I am, etc.,

S. C. DYKE,
Secretary, British Pathologists Association.

Wolverhampton, March 10th.

OPTICIANS AND OPHTHALMIC BENEFIT.

SIR,—I send the following account in the hope that it may be sufficiently interesting for publication. It also tends to prove that these societies (and I believe that there are many) who direct their members to go to the opticians for ophthalmic benefit are not always in the right.

In December, 1926, a woman factory worker, aged 34, was sent to me by her panel doctor, who recognized that the headaches from which she was constantly suffering were due to refractive errors. Four years ago she had been to a qualified optician (who, by the way, had charged her £2 7s. 6d. for a pair of rimless spectacles), and his prescription was for right and left eyes +0.5 axis cylinder horizontal.

She wore these spectacles for one year, but obtaining no relief she went to him again, and he then altered the lenses to −0.5 cylinder axis horizontal, right and left; for this change of lenses the charge made was £1 1s. Still obtaining no relief, the patient discontinued wearing the spectacles for a considerable time, and the headaches continued. She was then referred to me, and my notes show as follows:

No conjunctival injection. Pupils react to light, and media normal. Right vision 6/24 not improved. Left vision 6/18 not improved. Under homatropine her refraction was

R. +3.5 ⊕ +2. L. +2.5 ⊕ +1.75.

At a post-mydriatic test she preferred

R. $\frac{+0.25 \text{ sp.}}{+1.5 \text{ cyl. hor.}} = \frac{6}{6}$ L. $\frac{+0.25 \text{ sp.}}{+0.75 \text{ cyl. hor.}} = \frac{6}{6}$

These were prescribed for constant wear, and since wearing them she has been quite free from headaches.—I am, etc.,

A. G. C. POCOCK.

Leicester, Feb. 23rd.

THE SPAHLINGER TREATMENT.

THE following letter has been addressed to the President of the British Medical Association by the President and Secretary of the Central Committee of the Fédération des Médecins Suisses:

"MY DEAR COLLEAGUE,

"The Swiss medical faculty has for some time past been receiving a considerable number of inquiries from British doctors as to the extent to which the methods utilized by Mr. Spahlinger of Geneva for combating tuberculosis are known and utilized in Switzerland, and what is the opinion of the Swiss medical fraternity with regard to them.

"The Central Committee of the Swiss Medical Federation (Fédération des Médecins Suisses) has therefore decided to make and communicate to you the following declaration:

"(1) Mr. H. Spahlinger of Geneva, 'licencié en droit,' holds no medical degree, and so is not a member of our Federation.

"(2) The serums and vaccines that he claims to have discovered for the cure of tuberculosis have so far only been applied in exceptional cases by Swiss doctors and for Swiss patients; moreover, the Swiss medical press has never published any communication either from Mr. Spahlinger himself or anyone else giving the composition of these serums and vaccines, the means by which they can be prepared or procured, and the therapeutic results that they have given. Any control in our country of the value of these serums and vaccines, or of the results obtained by their application, has therefore been impossible.

"(3) Consequently, Mr. Spahlinger's methods have so far remained unknown to the large majority of Swiss practitioners.

"(4) The Geneva Medical Society (Société Médicale de Genève) was asked by the Central Committee to give its opinion on the Spahlinger treatment. It replied that it was not at present in a position to give any opinion on Mr. Spahlinger's methods, as no published statement existed giving a sufficiently clear account of these methods to allow of their serious examination. The Geneva Medical Society further noted that Mr. Spahlinger's first statement in explanation of his system had been made to the society on the 2nd March, 1927, in order to enable it to comply with our request. This statement could not, however, be considered as in any way conclusive, since the ground plan of his work and the basis of his statement are purely theoretical, and have not yet been subjected to scientific investigation.

"We should be glad if you would bring this declaration to the notice of the members of your Association.

"We have the honour to remain,

"Yours faithfully,

"Dr. H. MAILLART, *President*,

"Dr. GARRAUX, *Secretary*,
of the Central Committee of the
Fédération des Médecins Suisses."

Geneva, March 8th.

Obituary.

FREDERICK ARMITAGE SOUTHAM, M.A.,

M.B.Oxon., F.R.C.S.Eng.,

Consulting Surgeon, Manchester Royal Infirmary; Emeritus Professor of Surgery, Manchester University.

WE greatly regret to announce the death of Mr. F. A. Southam, which took place on March 9th. Mr. Southam was the son of Dr. George Southam, who was honorary surgeon to the Manchester Royal Infirmary from 1847 to 1876. George Southam was lecturer in surgery at the old Chatham Street School of Medicine, which later joined with the School of Medicine in Pine Street, and subsequently amalgamated with Owens College. He was a prominent man in the medical life of Manchester in the middle of last century, and was President of the Council of the British Medical Association in 1872 and 1873.

Mr. F. A. Southam, who was born in Manchester in 1850, was sent to Rugby and went up to Trinity College, Oxford, in 1869. He graduated B.A. in 1873, taking a first class in natural science. He graduated M.A., and also M.B.Oxon. in 1877, and was admitted a Fellow of the Royal College of Surgeons of England in the same year. His clinical study was carried out in Manchester, where he won many honours. In 1876 he became physician's assistant at the Manchester Royal Infirmary, was house-physician in 1877, and resident surgical officer in 1878 and 1879. He was also for a time resident at the Barnes Convalescent Hospital. He was elected honorary assistant surgeon to the Manchester Royal Infirmary in 1880, and remained on the active staff until 1910, when he retired on reaching his sixtieth year. In 1914, owing to the shortage of surgeons due to the great war, he again took charge of a surgical unit at the infirmary, and helped the hospital during a time of great difficulty. During the war he also held the rank of Lieutenant-Colonel R.A.M.C., and did much valuable work at the Second Western General Hospital. Mr. Southam was the author of *Regional Surgery: a Manual for Students*, a book which was widely read by students of his day. He wrote many articles on surgical topics in the course of his life, one of the best known being that on fractures, in Treves's *Manual of Surgery*. In 1887 he received a certificate of honourable mention for the Jacksonian Prize at the Royal College of Surgeons of England for his dissertation on the subject of "The pathology, diagnosis, and treatment of tumours of the bladder." It is perhaps for his work on the bladder and on vesical calculus that Mr. Southam was best known. In 1904 he published a paper in this JOURNAL on a series of 120 operations for vesical calculi. To the end of his life he showed great interest in this subject, and as recently as two years ago a letter from him was published in the BRITISH MEDICAL JOURNAL on the question of the treatment of bladder stone. He was also one of the pioneers in the early operative treatment of acute appendicitis, and published several important articles on the subject when this disease first became recognized. He was lecturer in operative surgery at the Victoria University, Manchester, for a number of years, and later held the appointment of professor of clinical surgery at the University. He was a past president of the Manchester Medical, Pathological, and Clinical Societies, and was an honorary member of the Manchester Surgical Society. He was for many years a member of the British Medical Association and took an active part in its meetings. He was secretary of the Section of Surgery at the Annual Meeting at Birmingham in 1880, vice-president of the Section of Diseases of Children when the British Medical Association held its annual gathering in London in 1895, and vice-president of the Section of Surgery at the Annual Meetings in Carlisle and Manchester in 1825 and 1902 respectively. He held a number of consultative positions in connexion with the medical institutions of Manchester; among these were consulting surgeon to the Manchester Royal Infirmary, the Northern Hospital for Women and Children, the Manchester Christie Hospital, and the Victoria Memorial Jewish Hospital. He was formerly examiner in surgery to the Universities of Oxford and Manchester.

F. A. SOUTHAM, F.R.C.S.

Mr. Southam was a man of unusual character, combining quiet determination with rare kindliness and goodness of heart, and was pre-eminent as an instructor. His teaching was of the simplest and clearest character, without being confusing or deep, and at the same time perfectly definite. His old pupils speak in the highest terms of his judgement, which was unerring, and his operative skill, which was unequalled in his day. He was a cool and careful operator, and was never at a loss in any surgical emergency. Perhaps one of the secrets of his success in surgery was his rapidity in operating. His ward classes and clinical lectures on surgery were the best given in their time, and rarely surgeons, even at the present day, equal him in directness. Few men have been held in such affection by those who came under his hands, both as a teacher and an operator. He was a great athlete in his earlier days, winning his blue at Oxford for short-distance running, and even to the end he was a well known figure in the Manchester streets, always preferring walking to driving. It is recorded that people living in his neighbourhood set their clocks by the regularity of his daily peregrinations until the last week of his life. He was a keen golfer, even to the extent of having a practice net fitted up in his own home. In 1882 he married Amy Florence Hughes, daughter of the headmaster of Blundell's School, and had a very happy married life. He was left a widower four years ago, and is survived by his two sons, the Rev. Eric Southam, vicar of St. Mark's, Portsmouth, and Mr. A. H. Southam, M.Ch.Oxon., F.R.C.S.Eng., who is carrying on the surgical tradition of the family in Manchester.

The funeral service, which was conducted by his old rector the Bishop of Middleton, took place at the Manchester Crematorium on March 11th, and was largely attended by members of the medical and surgical profession in and around Manchester. The ashes were deposited in the family vault at St. John's, Pendlebury, the following morning.

DR. WILSHAW WILLIAM GROSVENOR, who died on January 8th at Bury Vicarage, Sussex, received his medical education at the University of Cambridge and St. Bartholomew's Hospital. He obtained the diplomas M.R.C.S.Eng. and L.R.C.P.Lond. in 1888, and graduated M.B.Dublin in 1894, proceeding M.D. in the following year. For many years Dr. Grosvenor carried on a successful practice at Gloucester, and was a strong supporter of the British Medical Association. He was honorary secretary of the

Gloucester Branch from 1899 to 1902, and one of the honorary local secretaries of the Annual Meeting at Cheltenham in 1901. He was elected president of the Gloucester Branch in 1911, and served on the Branch Council from 1912 to 1919.

Dr. FREDERIC WILLIAM POLLARD of Blackburn died on February 25th, aged 51 years. He was the son of the late Dr. W. R. Pollard, who for nearly half a century was medical officer to the Blackburn rural district council. His early education was conducted by a private tutor, and he studied medicine at the University of Edinburgh and Trinity College, Dublin. He took the diplomas of Lic.Med., L.Ch., and L.M. in 1901, and graduated M.B., B.Ch., B.A.O.Dub. in 1924. After serving as clinical clerk to the Meath Hospital, Dublin, he joined his father in practice and subsequently started on his own account. For several years he was a district medical officer, and had to resign the appointment owing to pressure of other work. Dr. Pollard was a member of the Blackburn Division of the British Medical Association, and during the war served at the Whalley Military Hospital; he is survived by his widow. *The funeral, which took place on March 1st,* was attended by many members of the medical profession in Blackburn and the surrounding district.

The death occurred rather suddenly, on February 14th, of Dr. JOHN BRANGAN, Kells, co. Meath, at the age of 56. He had an anginal attack a few days previously, but apparently recovered, and visited some patients on the day of his death; a second attack occurred in the evening, and he succumbed. A native of co. Meath, he was educated at St. Malachy's College, Belfast, and the Catholic University of Dublin, obtaining the diplomas of L.R.C.P. and S.Ed. and L.R.F.P.S.Glasg. in 1899. He was appointed medical officer to Kilskeer Dispensary in 1900, coroner for North Meath shortly afterwards, a justice of the peace for the county, and later a peace commissioner. Dr. Brangan had a very extensive practice, and was held in the highest esteem by all classes of the community. His splendid physique, with his cheery and friendly smile, inspired confidence in his patients, who recognized in him a sincere friend and a skilled physician. Apart from his profession, his special hobby was the breeding and racing of horses, and during the past quarter of a century he owned some very good thoroughbreds, who won races on both sides of the Channel; Icila, Tisheen, Hairpin II, Parapluie, and Gardenrath, to mention only a few of his animals, were well known in England. His funeral was one of the largest ever seen in county Meath, and was representative of every class and creed. Dr. Brangan leaves a widow and a family of seven. His eldest daughter and second son are members of the medical profession.

Dr. ISAAC WHITLA CORKEY of Epsom was one of those brilliant young Ulstermen whose services were lost to Ireland when the Irish Free State came into being. He was born at Warrenpoint, county Down, in 1892, and studied medicine at the University of Dublin, where he won a medical scholarship, graduating B.Ch. and B.A.O. in 1915, and later proceeding to the M.A., M.D., and M.Ch. degrees. He had a distinguished career in the war, when he served as medical officer with the Ulster Division and gained the Military Cross, and after demobilization from the R.A.M.C. at the end of the war he took the Fellowships of both the English and the Irish Colleges of Surgeons. In 1919 he was appointed assistant surgeon to Sir Patrick Dun's Hospital, Dublin, and had to all appearances a successful career before him in the Irish capital; but the Irish Free State and the methods of those who strove for its formation were both so distasteful to him that he threw up his appointment, settled at Epsom in partnership with another of his compatriots, and was appointed surgeon to St. Anthony's Hospital. Corkey (writes a former colleague) was in many ways a typical Irishman: impulsive, even hot-headed, generous, humorous, and, above all, eminently human. He had the defects of some of these qualities, in that it was often difficult to make him see both sides of any question, especially political or religious questions. But he never bore malice, was always as ready to laugh at himself as at anyone else, and was, in a word, a man whom anyone might be glad to call his friend. He was nephew to Sir William Whitla of Belfast. He leaves a widow and one very young child, to whom sympathy will be widely extended on the sudden loss of so brilliant and popular a member of the medical profession.

Dr. ANDREW THOMSON, who died in Edinburgh on February 19th at the age of 70, came from a well known Border family, who for several generations had held the farm of Hobton, Ancrum. Dr. Thomson graduated M.B., C.M. at Edinburgh in 1883, and thereafter practised for a time at Wakefield. He had retired from active practice about three years ago, and went to reside in Jedburgh. He was keenly interested in local sports, and in particular was an enthusiastic supporter of the Jedforest Football Club.

Dr. WILLIAM YOUNGSON DAVIDSON, who died on February 27th, after a very short illness, had practised in Smethwick for fifteen years. He received his medical education at Aberdeen, and graduated M.B., Ch.B. in 1908. He took great interest in municipal affairs, and particularly in the housing question, and he was an active member of the Conservative Association. In 1924 he was elected to the Smethwick Town Council as a representative of the Soho ward, and served on the health committee. He was a member of the British Medical Association, and served on the Executive Committee of the Birmingham Central Division in 1925. His funeral on March 2nd was attended by the Mayor of Smethwick and by representatives of the various organizations with which he had been connected.

Dr. ANDREW ROBERTSON of Halifax died on March 4th, aged 64 years. He was educated at the University of Edinburgh, where he graduated M.A. in 1882, and M.B., C.M. in 1888. After serving as assistant house-surgeon to the Halifax Infirmary he started practice in 1888. During the war he was a member of the St. Luke's War Hospital medical staff with the rank of Major R.A.M.C., and his name was amongst those brought to the notice of the Secretary of State for War for valuable services rendered. Dr. Robertson took a keen interest in cricket and football, in both of which games he excelled in his earlier years. He was a member of the Halifax Division of the British Medical Association; his widow and one son survive him.

Dr. JOHN MOORE SWAIN, of Long Clawson, Leicestershire, who was born in January, 1827, died on March 7th. He obtained the diploma L.S.A. in 1849, and the M.R.C.S. in the following year, being one of the first to register under the Medical Act of 1858. For between sixty and seventy years he practised in the Vale of Belvoir, and only retired about five years ago. He was well known for his generous gifts to local institutions. For nearly forty years Dr. Swain was a member of the British Medical Association, and a telegram was sent to him a few weeks ago by the President of the Association congratulating him on the attainment of his hundredth birthday.

The following well known foreign medical men have recently died: Dr. GABRIEL FERRÉ, professor of experimental medicine in the Bordeaux faculty of medicine; Dr. JUAN BARCIA CABELLERO, professor of anatomy and rector of the University of Santiago; Dr. MAX FINGERHUTH, joint editor of the *Schweizerische medizinische Wochenschrift*; Dr. WILLIAM OETTINGER, a Paris physician who was the author of works on diseases of the arteries and digestive system; Dr. CASPER HENDRIK KUHN, formerly professor of morbid anatomy and medical jurisprudence at Amsterdam; Professor KARL ERNST RANKE of Munich, a leading authority on tuberculosis, aged 56; Professor HEINRICH BENEDICT, director of the Jewish Hospital in Budapest, aged 54; and Dr. WILHELM FLEINER, formerly director of the medical policlinic at Heidelberg.

Medico-Legal.

HUME-SPRY *v.* SMITH AND WATSON.

BEFORE Mr. Justice McCardie and a special jury in the King's Bench Division the hearing was continued on Wednesday, March 9th, of the action brought by Mr. F. Hume-Spry against Dr. R. Percy Smith of Queen Anne Street, W., and Dr. A. H. Watson of Salisbury, for damages for alleged negligence in certifying him as a lunatic.

The defendants pleaded the protection of Section 330 of the Lunacy Act, 1890, because they acted in good faith and with reasonable care; and, further, they relied on the Public Authorities Protection Act, 1893. A summarized report of the earlier proceedings appeared at page 495 of our last issue.

Plaintiff's Case Continued.

Dr. J. S. Risien Russell, of Wimpole Street, gave evidence for the plaintiff. He saw Mr. Hume-Spry on December 17th, 1925, and, after reading the certificates of the defendant doctors, he questioned the plaintiff as to the examinations he had been subjected to before certification. He saw the plaintiff again in January, 1926, and after a further complete examination, both physical and mental, he could not find any evidence of insanity—or, from the evidence before him, that he had ever been insane. The "delusion" mentioned in the certificates was a perfectly possible state of things—Mrs. Hume-Spry's misconduct—and was not the same thing as a *man thinking that he was the Deity, or the King of England, or* the Emperor of Germany. The history which he heard was compatible with psychasthenia, in which the patient might behave in the manner popularly known as that of a "raving lunatic," or he might be morose and seek solitude as the plaintiff was said to have done. The condition was particularly common since the war. In the witness's opinion the certificates of insanity ought not to have been given.

Mr. Neilson, K.C. (cross-examining): Assuming that Dr. Smith saw the case-book at Latchmere Hospital, was told the facts by Dr. Oliver, and had an interview with the plaintiff lasting an hour and three-quarters, are you prepared to say that he could not properly and honestly make up his mind that the patient should be put under control?—No; but if he had found at the examination anything which justified that, it must have appeared in the certificate, and there is not one word in this certificate which would justify a man's being certified.

Dr. Russell agreed that copies of the certificates went before the Board of Control, who had full control of institutions such as the Old Manor House, and that if they were not satisfied they could take action and send the patient out of the asylum.

Dr. T. B. Hyslop, of Portland Place, W., said he examined the plaintiff on March 3rd last, and found him of sound mind and understanding. During forty years he had never put down in a certificate any fact communicated by others. It was necessary to make a physical examination of a patient to exclude the possibility of the mental symptoms arising from some bodily illness. In his opinion, Dr. Percy Smith should have considered the physical as well as the mental aspect.

Cross-examined, Dr. Hyslop said Dr. Smith might have thought that he was justified in giving the certificate, but he (witness) would not have accepted hearsay evidence in dealing with a person's liberty without putting the matter to the patient himself. There was no obligation to certify; on the other hand, there was an obligation to the public and to the patient. In a social matter, such as an allegation of immorality against a wife, it was not the medical practice to go further than questioning, and, if necessary, cross-questioning, the patient about the suggestions of immorality.—"I think that many medical men have extreme courage in these matters. A doctor is always on the horns of a dilemma and is inadequately protected by the law."

Sir James Purves-Stewart spoke to examining the plaintiff on December 18th, 1925. It was not until he saw the letters written to Mrs. Hume-Spry by Dr. *Stodart-Walker* that he expressed an opinion. Then he declared that the "delusions" were not delusions, but beliefs founded on reasonable evidence. On physical examination he could find no evidence of mental disease at all, and he therefore came to the conclusion that the plaintiff was sane.

Cross-examined, the witness agreed that Dr. Smith, on March 13th, 1923, might properly have taken a view different from that which he had expressed, especially if he had been inadequately informed.

Mrs. Weller and Mrs. Thwaites, sisters of the plaintiff, also gave evidence.

Case for the Defendants.

Mr. Neilson, in opening for the defence, said Section 330 of the Lunacy Act, 1890, gave protection to *medical men in addition to that* afforded by the common law. That section provided that, if any medical man did anything in pursuance of that Act, he was not to be liable in any civil or criminal proceedings so long as he had acted in good faith and with reasonable care. If Dr. Smith and Dr. Watson gave their certificates honestly, and in the proper exercise of the skill which they possessed, they would not be liable, even though other medical men might think that the plaintiff was suffering from psychasthenia and not from unsoundness of mind. Doctors were entitled to differ, and when doctors had to examine a patient to ascertain the condition of his mind they had a very grave responsibility and had to make up their minds in circumstances of very great difficulty and complexity. They had to pay regard, not only to the interests of the patient, but also to those of the public. There was the added complication in the present case of the allegations between Mr. and Mrs. Hume-Spry. The defendants were not concerned with the truth or falsity of these allegations. The only things that mattered were their state of *knowledge when they gave their certificates, the care that they took* in examining the patient and in forming their opinion, and what the plaintiff's condition was on the material dates of certification.

Dr. Percy Smith, in evidence, said he had practised as a consulting physician on mental cases and nervous diseases since 1898. He had known Dr. Woods professionally since 1912, but not socially. He was asked over the telephone by Dr. Oliver, the medical superintendent under the Ministry of Pensions at Latchmere Hospital, to go and see the plaintiff. The symptoms displayed in the documents, and the story which he heard from Dr. Oliver, were facts which put him on inquiry. He regarded it as serious that the patient should threaten to kill Dr. Woods by shooting him with a revolver. The plaintiff looked very angry and suspicious. The interview lasted three-quarters of an hour. Then he saw Mrs. Hume-Spry, and he felt she was telling the truth. Turning on the gas in his wife's bedroom and putting a knife to his own throat were acts on the part of the plaintiff which he regarded as serious. Having seen the husband and wife and the documents, he then expressed his honest opinion that the plaintiff was insane and not a fit person to be at large. The fact that he knew Dr. Woods in the professional sense did not in any way influence him in the decision he came to, except that he felt that for a man in the position of Dr. Woods it was such a grave charge that he could not believe it.

Answering Mr. Justice McCardie, the witness said he regarded the plaintiff at the time he certified him as unfit to manage his affairs or to look after himself, and as being a danger to others. Continuing, Dr. Percy Smith said that the same evening he heard that the plaintiff had left the hospital and had not returned, and, as he considered it very dangerous for the plaintiff to be at large, he signed the certificate the next morning.

Cross-examined, Dr. Smith said he would not offer any opinion as to the plaintiff's sanity now. He had heard the plaintiff's evidence in that court as to the grounds for his belief that his wife had been unfaithful to him. They were much to the same effect as the statements the plaintiff made to him in March, 1923. He admitted he never examined the plaintiff physically. In reply to the Judge, who asked, "What is the final question before signing a certificate?" the witness replied that an important question was whether the patient was safe to be at large, or whether he was a danger either to himself or to others. A third question was whether the patient was marked by such unsoundness of mind as to require treatment in a mental hospital.

Sir H. Maddocks: Looking at the certificate, can you see anything in the facts observed by yourself which would justify you in certifying the plaintiff?—Yes, because he had, in my opinion, a delusion that his wife had committed misconduct with Dr. Woods and could prove it. I formed the opinion that that was a delusion after I had seen his wife, and because he said that the idea came to him with redoubled force from his environment and not from anything new.

The witness agreed that he did not ask the plaintiff whether he had threatened to kill Dr. Woods. One of the things to consider was the *bona fides* of the people who reported such threats. He agreed that a medical man who took out to dinner the attractive wife of one of his patients was very injudicious, but even if he had known in March, 1923, that Dr. Woods had taken Mrs. Hume-Spry out to dinner and had visited her at her flat, he would still have certified the husband, because there were other things which might have been put down in the certificate. He did not make any attempt to find out the truth of Mr. Hume-Spry's charges against Dr. Woods; he was not a magistrate. In reply to a question whether, if he had known as a fact that she had misconducted herself with Dr. Woods he would have signed the certificate, the witness said he did not suppose that he would. He added that if he had known of the letters from Dr. Stodart-Walker to Mrs. Hume-Spry—which in his view were flippant nonsense—he might possibly have had to take other steps before certifying Mr. Hume-Spry as suffering from delusions about his wife's infidelity.

Dr. Arthur Hubert Watson, in evidence, said he was a general practitioner at Salisbury. On March 17th, 1923, he saw the plaintiff at the Old Manor House, Salisbury, after he had had a conversation with Mrs. Hume-Spry and Dr. Martin. The interview lasted about half an hour, and the witness came to the conclusion that the plaintiff was obviously insane.

Mr. Justice McCardie: You saw him in the witness-box. Did his appearance and the way in which he answered questions resemble what you observed in March, 1923?—I will not say that it did not bear the slightest resemblance, but it was quite different.

He (witness) was scared and nervous of him, and felt relief in knowing that there were attendants outside. When he (the witness) gave his certificate he did not know that it was Dr. Percy Smith who had already certified the patient as being insane.

In cross-examination Dr. Watson said he knew an urgency order had been made against Mr. Hume-Spry before he saw him at the *Old Manor House on March 17th, 1923. He never saw the case-*book or anything in writing relating to the case; he heard the history from Dr. Martin (the proprietor), Mrs. Hume-Spry, and the patient. He agreed that he had put into the certificate he signed the statement that the plaintiff had tried to murder his wife "by turning on the gas and shutting the window last Monday." He knew now that that incident was alleged to have occurred nearly three months earlier. Witness added that when he put to the plaintiff his wife's denials about Dr. Woods, the plaintiff's account was confused. The plaintiff repeated the charges, but he formed the conclusion that the plaintiff was insane. He agreed with counsel that wildness and excitement might be due to the fact that a man was labouring under strong emotion, and the sanest man in a temper

might look like a madman. The plaintiff (whom he saw alone) did not offer him any violence, or utter any threats against anyone whilst he was with him.

Dr. W. J. O'Donovan of Harley Street, in his evidence, said the plaintiff and his wife occupied a flat in the same building as the witness and his wife in 1920. In March, or April, 1920, the witness was called in to see the plaintiff, who spoke of suicide; Mrs. Hume-Spry, in her husband's presence, said he had threatened to commit suicide, and had also threatened her. As a result of a letter the witness wrote to Dr. Woods that plaintiff "required expert psychological treatment or I am sure he will come to an untimely end," the plaintiff went into Palace Green Hospital. In January, 1922, the plaintiff told the witness that there was a liaison between Dr. Woods and Mrs. Hume-Spry, and that he thought that he should have compensation from Dr. Woods. Witness turned him out forthwith, telling him he was a blackguard, and that he was attempting blackmail. Plaintiff's ultimate certification seemed to the witness to be a "very natural development" from the symptoms he had observed in 1920. In cross-examination Dr. O'Donovan agreed that in 1920 his wife and Mrs. Hume-Spry became friendly, and that he (the witness) had known Dr. Woods since he was a medical student.

Mr. Herbert Francis, solicitor, of Bedford Row, in his evidence, said that in the autumn of 1921 he read a diary shown him by the plaintiff, and advised the plaintiff that, in his opinion, he had no case against his wife for divorce. Cross-examined, he agreed that in 1918 the plaintiff consulted him in regard to divorce proceedings, producing what purported to be original letters from a man to Mrs. Hume-Spry. Subject to the advice of counsel, the witness advised a petition for divorce, as the letters disclosed a prima facie case against the wife provided evidence was forthcoming. He heard later that the parties had become reconciled. He could not remember whether, when he had the diary, the last two pages were torn out, and he could only say that he did not remember that any other document accompanied the diary. When in 1926 the plaintiff's present solicitors approached him with regard to a confession, he said he had seen certain documents which were alleged to be the confession, but that he had no clear recollection of their contents. Re-examined, Mr. Francis said that, as a result of the divorce proceedings in 1918, the co-respondent paid £300, including costs, and that the petition was withdrawn.

Mr. Collings, clerk to the previous witness, spoke to the plaintiff bringing to him the diary in 1921, but he did not think that there was any other document. If a confession by Mrs. Hume-Spry of misconduct had accompanied the diary he thought he would have remembered it.

Mrs. Amelia Hume-Spry, in her evidence, denied committing adultery with the co-respondent cited in the divorce proceedings instituted in 1918. The man in question completely lost his head about her, and wrote her five letters because she avoided him. When her husband suggested a petition, the witness told him "it was nothing but an attempt to commit blackmail" and that she would not be a party to it. Her husband then suggested that a confession from her would clinch the matter, and she told him exactly what she thought of him. About that time her husband pretended to shoot himself with his revolver. "I understood that he would shoot me and then do away with himself, so I signed a confession. That was in 1918, and I have never signed one since." Eventually, the co-respondent paid £300 and the petition was withdrawn. Her husband then told her: "If you had gone through with the thing properly there would have been £3,000 instead of £300." What he meant by that was if she had really misconducted herself with the co-respondent. Her husband was never normal and was unmanageable. When he was at Palace Green Hospital she went to see him every day. Though he thought he was perfectly sane, she thought he was 75 per cent. insane.

*** There was an inaccuracy in the report of this case published in our last issue. On page 495, first column, appeared the words: "Mr. Hume-Spry remained at the Old Manor House until December, 1923, when he was certified by other doctors (Sir James Purves-Stewart, Dr. Risien Russell, and Dr. Hughes) as being perfectly sane." We understand that when at a later stage Sir Henry Maddocks, counsel for the plaintiff, repeated this date, Mr. Neilson, counsel for the defendants, immediately corrected the statement and pointed out that Sir J. Purves-Stewart and Dr. Russell did not see the patient until December, 1925, that is, until two and three-quarter years after the patient had been certified. This is clearly brought out in the report of their evidence printed above. Dr. Orr was the medical man who gave the certificate of sanity in January, 1924, when the patient was on leave of absence.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Rolleston Memorial Prize, 1928.

THIS prize, now of the value of about £100, is awarded every two years for original research in animal and vegetable morphology, physiology and pathology, or anthropology. The next award will be made in Trinity Term, 1928.

No candidate will be eligible (1) who has not either passed the examinations for the B.A. or the B.M. degree at Oxford, or for the B.A. or M.B. at Cambridge, or been admitted as an advanced student or as a student for the degree of B.Litt. or B.Sc. at Oxford, or as a research student for the degree of M.Litt. or M.Sc. or Ph.D. at Cambridge; (2) who has exceeded a period of six years from attaining one or other of these qualifications, or from attaining the first of such qualifications, if he has attained more than one; (3) who has exceeded ten years from his matriculation.

Candidates must forward their memoirs to the Registrar of the University of Oxford before March 31st, 1928. The memoirs may be printed, typewritten, or in manuscript. They should be inscribed "Rolleston Memorial Essay," and bear the name and address of the author. Memoirs already published are admitted to the competition. No account will be taken of any research which has not been prosecuted by the candidate subsequent to his matriculation.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on March 11th the degree of M.B., B.Chir. was conferred on G. Simon.

UNIVERSITY OF LONDON.

MR. ERNEST PLAYFAIR and Mr. Hugh Augustine Richards have been recognized as teachers of anaesthetics at King's College Hospital Medical School.

A readership in bacteriology and immunology, tenable at the London School of Hygiene and Tropical Medicine, is to be instituted.

The regulations for the academic Diploma in Psychology have been amended by the substitution of the words "the second Monday prior to the first Monday in July" for the words "the first Monday in July" on page 529 of the Red Book, 1926-27.

The regulations for the second examination for medical degrees, Part II, for internal students are to be amended by the deletion of the words "or general" in lines 1 and 2 of Section (v) on page 237 of the Red Book, 1926-27, and by the addition to the end of the same section of the following:

> Students who have passed the B.Sc. (General) Examination will be similarly exempted provided they have obtained at least second-class marks in the subject of physiology.

The regulations for external stud
(Blue Book, September, 1926, page

Professor T. H. Bryce has been
anatomy for science and medical examinations, in succession to Professor E. Fawcett, resigned.

The Chancellor has appointed Professor Rushton Parker to be his representative on the Court of the University of Liverpool.

The ceremony of Presentation Day will be held in the Royal Albert Hall on Wednesday, May 11th, at 3 p.m. The graduation dinner will take place the same evening at 7 p.m. in Fishmongers' Hall, London Bridge.

Applications for grants from the Dixon Fund, which are allocated annually for the purpose of assisting scientific investigations, must be sent in between April 1st and May 16th, and for the Thomas Smythe Hughes Medical Research Fund for assisting original medical research between May 2nd and June 15th. Further particulars can be obtained from the Academic Registrar.

VICTORIA UNIVERSITY OF MANCHESTER.

PROFESSOR H. S. RAPER, C.B.E., M.B., Ch.B., D.Sc., has been appointed Dean of the Medical School as from July next.

The following appointments have been made:

Assistant Lecturer in Physiological Chemistry: Mr. P. W. Clutterbuck, O.B.E., M.Sc., Ph.D.Leeds. Assistant Lecturer in Comparative Physiology: Mr. E. N. Willmer, B.A.Oxf., M.Sc.Manch. Assistant Lecturer in Anatomy: Miss Eugenia R. A. Cooper, M.Sc., M.D.Manch.

The following award has been made: The Hill Prize in biochemistry has been awarded to Eric Boyland.

UNIVERSITY OF DUBLIN.

AT a meeting of the Senate held on March 12th Graces were passed for conferring at the summer commencements on June 28th the honorary degree of M.D. on Sir Humphry Rolleston, Bt., K.C.B., Regius Professor of Physic at Cambridge, and of M.Ch. on Dr. Harvey Cushing, C.B., Emeritus Professor of Surgery in Harvard University.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on March 10th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

Licences and Diplomas.

Licences in Dental Surgery were granted to 56 candidates. Diplomas in Tropical Medicine and Hygiene were granted jointly with the Royal College of Physicians to 24 candidates.

Appointments.

Mr. C. H. Fagge was appointed the representative of the College on the [illegible] of the Schiff Home of Recovery. Mr. V. [illegible] d a representative of the College on the [illegible] of London. Mr. Victor Bonney was elected a representative of the College on the Central Midwives Board for the period of one year from March 31st next. Sir H. J. Waring was re-elected a representative of the College in the General Council of Medical Education and Registration of the United Kingdom. Dr. George Parker, of Clifton, Bristol, was nominated as Thomas Vicary lecturer for the ensuing year.

Honorary Fellowships.

The following were elected honorary Fellows in connexion with the Lister centenary celebrations to be held in April next, the

elections being subject to the condition of personal attendance at the College to receive the Diploma:

Alessandri, Roberto, Professor of Surgery, Faculty of Medicine and Surgery, Rome.
Archibald, Edward William, Professor of Clinical Surgery and Surgery, McGill University, Montreal.
Krogius, Frans Ali Bruno, Professor of Clinical Surgery, Faculty of Medicine, University of Helsingfors.
Lecène, P., Professor of Surgical Pathology, Faculty of Medicine, University of Paris.
Leriche, René, Professor of Clinical Surgery, Faculty of Medicine, University of Strasbourg.
Matas, Rudolph, Professor of Surgery, Tulane University of Louisiana, New Orleans.
Willems, Charles, Professor of Operative Medicine, Faculty of Medicine, University of Liège.

Representation of Members on Council.

A report was received from a committee which had had under consideration the resolution carried at the annual meeting of Fellows and Members in November regarding the question of admitting Members to direct representation upon the Council of the College. A recommendation from the committee was adopted, and the exact form of question to be put to the Fellows will be settled at a future meeting of the Council.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

HERBERT FREDERICK BLACKLEE, M.B., Ch.B., Barrow-in-Furness, has been admitted after examination as a Fellow of Faculty.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE Parliamentary Medical Committee met at the House of Commons on March 9th, and re-elected Dr. Fremantle its chairman for the present session, and Dr. Graham Little its honorary secretary. The committee received and conferred with a deputation from the British Medical Association about the Dogs' Protection Bill and the steps which might be desirable in order to set forth the medical case for the use of dogs in experimental research. The committee approved the suggestion of the British Medical Association to call a conference of representatives of medical bodies in order to make plain to the public the opinion of those concerned in medical teaching and the progress of scientific medicine on the attacks made on medical research, and to explain why this work is in the interests of the public.

The Mental Deficiency Bill.

Definition of Mental Deficiency.

The text of the Mental Deficiency Bill, which was set down for second reading on March 18th, differed from that introduced last session chiefly in the addition to the definition of mental deficiency of a subsection requiring that the condition must have existed in the patient before the age of 18 years. This subsection ran:

"For the purposes of this section 'mental defectiveness' means a condition of arrested or incomplete development of mind existing before the age of 18 years, whether arising from inherent causes or induced by disease or injury."

Memorandum.

The memorandum prefixed to the bill is as follows:

1. The main object of this Bill is to amend the definitions of defectives which are contained in the Mental Deficiency Act, 1913. Under these definitions only persons who are mentally defective from birth or from an early age come within the Act, and there is thus no power to deal with cases where the defectiveness arises at a later stage. An illustration is afforded by the disease known as encephalitis lethargica, though these particularly need the sort of care and treatment which can be provided in a mental deficiency colony. The effect of the Bill (Clause 1) is to eliminate the words "from birth or from an early age" and to bring within the scope of the Act all cases of mental deficiency which arise before the age of eighteen, whether due to inherent causes or induced by disease or injury.

2. Under the existing Act a defective may be placed under care if he is found to be also "neglected, abandoned or without visible means of support or cruelly treated." Clause 2 (1) extends this provision to a case where the care or training which the defective requires cannot be provided in his own home.

3. Subsections (2) and (3) of Clause 2 are designed to provide that any case may be dealt with by any one of the three methods recognized by the Act, viz., providing supervision, placing under guardianship or sending to an institution, while Clause 3 merely introduces a drafting amendment into the Act of 1913 to make it clear that section four of that Act only applies to the two latter of these methods.

4. Clause 4 will enable an order to be made on a petition without the consent of the parent or guardian, if, owing to his being abroad, the attempt to obtain it would unduly delay the proceedings on the petition.

5. Clause 5 provides that if a patient is away from an institution on leave of absence, he need not be brought back to the institution for examination in connexion with the continuation report required under section eleven of the Act.

6. Clause 6 makes explicit the power and duty of local authorities to provide suitable training for mental defectives whilst under supervision as well as in institutions.

7. Although the Act authorises the combination of local authorities, it does not enable a local authority to provide additional beds which could be lent to other authorities. Clause 7 (1) provides for such a procedure.

8. Clause 7 (2) enables the local mental deficiency authority and the local education authority (who have responsibility for certain classes of defectives of school age) to provide an institution jointly.

Notices of intention to move the rejection of the bill were given from the Labour benches.

The Navy Estimates.

On March 14th Mr. Bridgeman, in his statement on the Navy Estimates, said that recruitment for the Royal Naval Medical Service had been unsatisfactory for some considerable time. A committee had been set up to look into the conditions of the Service, and as a result certain improvements had been effected, which were notified last July in Fleet Orders. Greater facilities had been given to young medical officers to specialize in various branches of their profession which were not naturally easily available in sea service. Improved allowances had been given to holders of specialized posts, and charge pay to medical officers in charge of hospital and sick quarters had been approved. Any candidate who held a house appointment at a recognized hospital was allowed to ante-date his seniority by one year, the object of that being to attract the most efficient of the younger medical students. The establishment of dental officers had been increased from 48 to 64.

Sir B. Falle said that if a man fell ill in the navy he was sent to the fleet surgeon, who, on his own responsibility alone, decided whether the man was to be discharged from the service or not. That was absolutely wrong. The medical service in the navy was a great service, and the men in it were as able as could be found anywhere, but it should not rest with one man to decide a matter of this kind. If a man was going to be thrown out he should have the right to go before a board. He suggested that if this board consisted of a fleet surgeon, a civil practitioner, and a man like the town clerk of Portsmouth, the navy would be satisfied to abide by its decisions. The number of men thrown out of the service this year for tuberculosis alone was 196; only six of them, or about 3 per cent., were given any pension for the illness they had contracted in the service. Men suffering from tuberculosis dare not go sick, because if they did they knew that the fleet surgeon would throw them out on the beach. Appeal to the Admiralty should be made automatic and a matter of right.

Lieut.-Colonel Headlam doubted whether other medical opinion could be got so easily as Sir B. Falle imagined. If Sir B. Falle would let him know of a definite case where men had been hindered from appealing to the Admiralty, the matter should be looked into.

Later in the debate Mr. Bridgeman said he was not entirely satisfied with the arrangements for invalidity pensions regarding the attribution of disease. He would look into the matter and see if anything more could be done.

Flying Accidents.

During the discussion of the Air Estimates, on March 10th, Mr. Baldwin spoke on the causes of accidents in the Air Force. He said the proportion of accidents due to remediable causes was very small. Few could be traced to the failure of the human element on the ground, and very few to faulty design. It was not the fact that older designs of aeroplane were more prone to disaster. The type of man who made the flying pilot was the adventurous, quick-brained, with great reserve of nervous power. He asked the House to remember the elation of a young man of that temperament who had just learnt the mastery of the aeroplane. The great majority of accidents happened from a slight error of judgement on the part of pilots, and most of them within the first year or two of flying. Captain Garro-Jones said he had been in more than one aeroplane accident. He asked what were the regulations on the consumption of alcoholic drink in the flying squadrons. In the fine, swift judgements required of an aeroplane pilot one alcoholic drink would make the difference between disaster and safety. No pilot should be allowed to consume alcoholic liquor before he flew on any day. Science demanded that decision. Sir Philip Sassoon said the Air Ministry was anxious and careful to have as little drinking as possible in the Air Force. There was drinking. Drunkenness was an offence against the Air Force Regulations, and was carefully watched.

On March 14th Sir S. Hoare (Secretary for Air) told Mr. Hore-Belisha that 263 airmen were invalided from the Service in 1926. Of these, 230 were refused pensions on the ground of no attributability. Of thirty-five appeals against the original decision six were allowed, but in three of these cases the degree of disablement was under 20 per cent.

Boys in Mines: Miner's Nystagmus.

Colonel Lane-Fox told Dr. Davies, on March 15th, that boys of 14 years of age were permitted to work in coal mines without a previous medical examination for fitness; and that under the Factories and Workshops Acts no child of 14 years of age was permitted to work without a previous medical examination by the

certifying factory surgeon. The existing system of examination under the Factories and Workshops Acts, however, had been recently condemned by a committee of inquiry, and an improved system of examination was to be submitted to the House in the Factories Bill. If it was approved, the application of similar provisions to mines and quarries would certainly be considered.

On the same day Colonel Lane-Fox told Mr. Short that in 1925 the number of new cases of miner's nystagmus in which compensation was paid was 3,444, and the number continued from previous years was 7,890. The figures for 1926 were not yet available. The Mining Association and the Miners' Federation had been invited to co-operate with the Home Office to give effect to the recommendation of the Nystagmus Committee, and continual efforts were being made to improve lighting in mines. Colonel Lane-Fox further stated that the average time spent below ground each working day by the miners in coalfields where the full eight hours had been enforced by the employers was approximately eight and a half hours, with a shorter period on Saturdays in many districts.

Twenty persons under 18 years of age were killed in coal mines in Great Britain during the months of December, 1926, and January and February, 1927.

Small-pox.—Answering a member who has recently made many requests for statistical details concerning small-pox, Mr. Neville Chamberlain said: "I would point out that these particulars can be obtained from the weekly return of infectious diseases published by the Registrar-General."

Royal Commission on Lunacy.—The Minister of Health states that it is not practicable to prepare in time for introduction in the present session a bill incorporating the recommendations which the Government is able to adopt from the Report of the Royal Commission on Lunacy and Mental Disorder.

Research in Tuberculosis.—During 1926 the Medical Research Council spent £4,846 in research upon specific problems of tuberculosis. This excludes the cost of research into fundamental problems of which the bearing upon tuberculosis could not be calculated, and also the cost of work in this subject by members of the Council's own staff in the National Institute for Medical Research.

Anthrax in Menageries.—Mr. Guinness, replying to Sir W. Davison, on March 15th, said that in view of the recent outbreak of anthrax at the Zoological Gardens in London, he was at present considering the advisability of including within the scope of the Anthrax Order of 1910 all animals susceptible to anthrax which were kept in public or private zoological collections and travelling manageries.

Pensions.—In a reply to Sir W. de Frece, Major Tryon said he was satisfied that the hospital accommodation available was fully adequate to the requirements of the Ministry of Pensions. The average waiting period for admission to hospital did not exceed three to four days. The geographical distribution of the hospitals was as good as could be obtained. Answering Mr. Paling, Major Tryon said he did not know of any general discontent at the time which passed between a medical board and the communication of the result to the applicants. In a few cases expert opinion or additional evidence might have to be obtained, but such cases were diminishing in number. In an answer to Major Hills, Major Tryon said the wooden limb had now been so improved that it was lighter than the metal limb. In many cases it was regarded both by the pensioner and the surgeon as more suitable, especially in amputations below the knee.

Blind and Partially Blind Children.—Lord Eustace Percy states that the provision in certified special schools for totally blind children between the ages of 5 and 16 is, generally speaking, complete. Thirteen authorities had special schools for partially blind children, and fifteen or twenty authorities either admitted partially blind children to their own schools for the blind or sent them to such institutions elsewhere. In 1925 there were 2,000 blind children of school age and 4,692 partially blind children in England and Wales. On March 14th Lord Eustace Percy told Mr. R. Morrison that on March 31st, 1926, there were in certified special schools for the blind 613 children aged between 13 and 14, 361 between 14 and 15, 288 between 15 and 16, and 54 aged 16 and over. There were 496 deaf children aged between 13 and 14, 480 between 14 and 15, 416 between 15 and 16, and 71 aged 16 and over.

Mentally and Physically Defective Children.—Lord Eustace Percy stated on March 14th that in certified special schools for the mentally defective there were on March 31st, 1926, 2,629 children aged between 13 and 14, 2,103 between 14 and 15, 1,465 between 15 and 16, and 241 aged 16 and over. Physically defectives in special schools numbered 2,486 between 13 and 14 years of age, 1,360 between 14 and 15, 770 between 15 and 16, and 100 aged 16 and over. Epileptics numbered 96 between 13 and 14, 96 between 14 and 15, 76 between 15 and 16, and 13 aged 16 and over.

Invaliding from the Army.—Captain King told Mr. Hore-Belisha, on March 15th, that the exact number of men invalided from the army during 1926 was not available, but the total number of disability cases (including those of men already discharged) dealt with by the Chelsea Commissioners during that year was 2,546. In 2,100 cases the disability was found to be not attributable to military service, but 639 of the men concerned were eligible for non-attributable awards of gratuity or temporary pension. It was not possible to distinguish between appeals made by the men themselves and cases referred to the War Office by the Chelsea Commissioners. The approximate number of cases referred under both heads was 137, and the decision was modified in 59. There were, in all probability, other cases which did not necessarily come before the Chelsea Commissioners. Dr. Davies asked if the right hon. gentleman thought it possible that the present methods of assessment could be improved. Captain King replied that the present method of assessment was proving satisfactory. The question of an appeal tribunal had been considered on many occasions, and it was not considered necessary to set one up.

Foot-and-Mouth Disease.—On March 15th, in the House of Commons, Mr. Guinness moved the second reading of the Diseases of Animals Bill, which had already passed the Lords. The measure seeks to improve and modernize methods of defence against contagious diseases in animals. He explained that the decrease in foot-and-mouth disease was due to the embargo put on after the outbreak in a bacon factory at Carluke. The report of the Foot-and-Mouth Disease Committee confirmed the Government's action, because it gave an account of experiments which reproduced the conditions which occurred at Carluke. Healthy pig carcasses were splashed or smeared with the infected blood of other pigs. They were kept at a temperature of 15° C., and four days afterwards rinsings were taken, reproducing the condition of the effluent at Carluke. They were found to be capable of infecting healthy animals with foot-and-mouth disease.

Gas Warfare.—Sir L. Worthington-Evans states that the Government has information that the study of gas warfare is being actively pursued in Soviet Russia. Numerous factories have been set up and are in course of erection. There is not the slightest doubt that much greater preparations are being made in Russia than anywhere else in the world.

Notes in Brief.

On March 14th the Sale of Food and Drugs Bill passed through the report stage and was read the third time in the Commons, and on March 15th was read the first time in the Lords.

Asked why imports of phenacetin, hydroquinone, and other chemical substances had not been exempted for liability to duty, Sir Burton Chadwick said that an Order had been made on March 7th exempting certain of these substances from duty.

The United States has been invited to define its attitude towards the Opium Convention adopted at Geneva in 1925.

In 1926 factory inspectors visited 101,962 factories out of 129,695 in England and Wales.

The number of dairy farms in England and Wales is estimated at over 200,000. Of these, 220 were visited in 1926 by inspectors of the Ministry of Health.

From September 1st, 1925, to December 31st, 1926, 23,369 cows were slaughtered by local authorities under the Tuberculosis Order, 1925.

Medical News.

SIR THOMAS HORDER, Bt., M.D., will preside at the "Wiltshiremen in London" annual dinner at the Connaught Rooms on April 2nd next.

AT a sessional meeting of the Royal Sanitary Institute on Friday, March 25th, in the Town Hall, Leeds, a discussion on cancer will be opened by Sir Berkeley Moynihan, Bt., P.R.C.S., followed by Professor R. D. Passey, M.D., Director of Cancer Research, University of Leeds. The chair will be taken at 5 p.m. by Dr. G. F. Buchan.

DR. R. TRAVERS SMITH will lecture for the Fellowship of Medicine on emergencies in neurological practice on March 24th, at 5 p.m., at the Medical Society, 11, Chandos Street, W. On March 22nd Mr. N. C. Lake will give a clinical demonstration in surgery at Charing Cross Hospital at 2 p.m., and ophthalmological demonstrations will be given at the Central London Ophthalmic Hospital at 4 p.m. on March 23rd by Mr. Levy, on the 24th by Miss Mann, and on the 25th by Mr. Williamson-Noble. The lecture and these demonstrations are free to medical practitioners. An all-day comprehensive course in orthopaedics is in progress at the Royal National Orthopaedic Hospital, and will continue until April 2nd. A two weeks' course in the late afternoons will begin on March 21st at the London Temperance Hospital for the benefit primarily of general practitioners. From March 28th to April 9th the Queen's Hospital will hold a special all-day course in diseases of children. At the Royal Eye Hospital there will be a series of afternoon demonstrations on the diagnosis and treatment of diseases of the eye from March 28th to April 8th. The Fellowship arranges for practical courses in anaesthetics and obstetrics and also for clinical assistantships in gynaecology. Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE new Health Committee of the League of Nations, whose tenure of office began on January 1st last and will run for three years, has held its first meeting. Dr. Madsen of Copenhagen was elected president, and Dr. Cumpston of Melbourne, Dr. Alice Hamilton of Harvard, and Professor Winslow of Yale were appointed expert assessors. After reviewing the work of its various commissions the committee decided to appoint a committee of experts on the relation of health insurance to public health services, and to proceed with the inquiry regarding infant welfare. It approved the

steps taken to collect information regarding the influenza epidemic. It expressed satisfaction at the progress of the Singapore bureau, and welcomed the proposal to establish a subcentre at Melbourne. It accepted a suggestion to undertake research into the subject of plague prevention. The courses on malaria in London, Hamburg, and Paris are to be held again this year, with field work in Italy, Spain, and Jugo-Slavia.

AT the last meeting of the Central Midwives Board for England and Wales, with Sir Francis Champneys in the chair, an intimation was received from the Midwives Institute that Dr. Fairbairn, Miss A. A. I. Pollard, and Miss M. E. Pearson had been reappointed as its representatives on the Board. It was resolved to reply to the county medical officer of health for Durham that in the opinion of the Board a midwife, when she had been in contact with an infectious case, should notify the local supervising authority, undergo disinfection in the manner prescribed by the local supervising authority, and await the permission of the local supervising authority before attending other maternity patients.

HEALTH Week will be observed from October 2nd to 8th on the same lines as in previous years. During 1926 meetings and exhibitions were arranged in connexion with Health Week by over eighty local authorities, several county councils organizing celebrations in numerous centres. Health Week was also observed in India, South Africa, Australia, New Zealand, Ceylon, and the West Indies.

AN appeal for volunteers to join the blood transfusion service, organized by the British Red Cross Society, the British Hospitals Association, and the Rover Scouts, has been issued. The total number of volunteers at present on the list is about 350, but during 1926 the number of calls made and answered was 737, and as the number of appeals is increasing (there have been 122 already this year) the committee fears that it will soon be unable to meet the demands. The appeal, which is signed by Sir Arthur Stanley for the British Red Cross Society, by Lord Knutsford for the British Hospitals Association, and by C. Lisle Watson for the Rover Scouts, asks employers to permit volunteers in their service to act in emergency cases during business hours. At present only fifty volunteers are available during the daytime, and most of them have already acted once this year. The committee will send a speaker to institutions interested, and individual inquirers may obtain particulars from the Honorary Secretary, 210, Peckham Rye, S.E.22. (Telephone, night and day, New Cross 1606.)

THERE has been a further substantial decline in the number of deaths recorded from influenza throughout the country. The total number of deaths from this cause in the great towns of England and Wales during the week ended March 12th was 572 compared with 898 in the previous week and 1,023 in the week before that. In London 49 deaths were notified as compared with 69 and 81 in the two previous weeks; and in the outer ring of the metropolis 24 as against 44 and 67. Reports received by the Scottish Board of Health indicate that in most parts of Scotland the influenza epidemic was last week definitely on the wane. The decline was very noticeable in Dundee and Aberdeen. In Ayr and in Orkney, however, the disease is still spreading, and in Fife there is little sign of diminution as yet.

VACANCIES exist at present for medical officers in the Malayan Medical Service. Candidates should be British subjects of European parentage and not over 35 years of age. Further particulars are given in our advertisement pages.

WE are informed that the British College of Nurses, endowed by an anonymous donor with £100,000, has secured 39, Portland Place, London, W.1, as headquarters. The college and its governing body the council are composed entirely of registered nurses.

THE late Dr. Samuel Clarke Noble of Kendal, who died in December last, aged 89, has left estate of the gross value of £38,807, with net personalty £33,066. His bequests on the death of his wife included £3,000 to Balliol College, Oxford, for the foundation of an Eric Raymond Noble scholarship; £300 to the Medical Mission of the Church Missionary Society; £1,150 to Dr. Barnardo's Homes; £1,000 to the Kendal Grammar School for a scholarship at Oxford; £1,500 to the Westmorland County Hospital for the endowment of three beds in the children's ward. The ultimate residue of the property is to be divided in three equal parts between the Middlesex Hospital Medical School for the endowment of a Hugh Percy Noble research scholarship, preferably on cancer or diabetes, in remembrance of his son; to Balliol College for the foundation of an open classical scholarship; and to Dr. Barnardo's Homes for general purposes.

THE late Sir Isambard Owen has left estate valued at £9,234.

THE International Labour Office has published six more pamphlets (Nos. 58 to 63) dealing with miner's nystagmus; the treatment of industrial waste water; the postal, telegraphic, and telephonic services; trinitrotoluene, trinitroxylene, and trioxybenzene; tuberculosis and silicosis; and aluminium and amber. They may be obtained from the London correspondent of the International Labour Office, 12, Victoria Street, S.W.1.

A MINISTRY of Health has been established recently in Denmark.

THE eighth International Congress of Actuaries will be held in the Guildhall, London, from June 27th to 30th, under the honorary presidency of the Prince of Wales. Many delegates are expected from the Dominions, the United States, Europe, and other parts of the world, in view of the public and professional interest taken in the application of actuarial science to life insurance, and to old age and invalidity pensions.

THE fourth Spanish Congress of Pediatrics, which will be held at Valencia in May under the presidency of Dr. Juan Moret, dean of the medical faculty of Valencia, will consist of four sections devoted respectively to the hygiene and protection of infancy, medical diseases of children, surgery and orthopaedics, and pedagogy.

THE proceedings of the Twelfth Congress of Northern Countries, held at Stockholm from August 27th to 29th, have been recently published in a special supplement of *Acta Medica Scandinavica*, the communications appearing in English, French, or German.

DR. AUVRAY has been elected a member of the Académie de Médecine in place of the late Professor Le Dentu in the section of surgery and obstetrics. Professors Lejars and Sebileau of Paris have been elected corresponding foreign members of the Belgian Royal Academy of Medicine.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

"ARCHIVES OF DISEASE IN CHILDHOOD."

DR. A. H. LOWTHER (St. Aubyn's, Burnham-on-Sea) is anxious to read the issues of the *Archives of Disease in Childhood* for August and October. These numbers are out of print, and Dr. Lowther would like to borrow or buy copies of them.

NERVOUS VOMITING.

DR. W. NUNAN (Bombay) writes in reply to "H. W. B." (JOURNAL, October 9th, 1926, p. 670) to recommend resort to suggestion.

MORBID SHYNESS IN A CHILD.

DR. R. MACD. LADELL (Birmingham) writes: "The letter of 'K. H. G.' in the JOURNAL of February 26th (p. 410), asking for suggestions as to the treatment of excessive shyness in a child of 8, is evidence of the lack of appreciation still shown by the majority of medical practitioners as to the possibilities of psychotherapy. Such a case should, as a matter of course, be taken for advice to a medical psychologist. Obviously to treat the cause of the shyness one must be aware of what is passing in the child's mind, and this can only be done by a process of psychological analysis." Dr. Ladell looks forward to the time when psychological clinics will be established in every large town.

CHRONIC URTICARIA.

"J. B. S." writes: "Pruritus" should again examine the urine of his patient for sugar, with a specimen of high specific gravity. Not a large amount of sugar, but a small amount—say, 3 per 1,000—for which the "Char test" is the best. Treat the patient as a potential diabetic, perhaps by heredity. Cut off starch and sugar and give liquor ammonii acetatis to act on the skin. Consider also occupation.

RURAL WATER SUPPLIES.

In reply to Dr. D. M. Macdonald (Arnside, Westmorland), it may be stated that the Public Health (Water) Act, 1878, which is still current, places upon a rural sanitary authority the duty of seeing that every inhabited house in its area has a convenient and adequate supply of wholesome water, and empowers the rural sanitary authority to call upon an owner to provide such supply where requisite. If the owner fails to comply after statutory notices given the rural sanitary authority may itself provide the supply and recover expenses. These provisions, however, do not relieve the rural sanitary authority of its general duty under Section 51 of the Public Health Act, 1875, to provide its district or part of it with a wholesome water supply where necessary on health grounds. A rural sanitary authority is a rural district council—that is to say, the council of a union or portion of a union which is not in an urban district. The medical officer and the sanitary inspector of the rural sanitary local Government shed from a rural district council, has certain water duties. It may utilize a well, spring, or stream, and provide facilities for obtaining water therefrom, but its borrowing powers are limited under statute and are subject to the consent of the parish meeting.

INCOME TAX.

Motor Car Transactions.

"P. G. S. C." bought a car in 1924, but found it unsuitable for his neighbourhood and sold it in the same year at a loss of £95, purchasing a heavier car for £310. The assessor allowed the £95 as an expense of the year 1924, but refuses the 20 per cent. depreciation allowance for 1926–27 unless the former allowance is cancelled.

*** If we have gathered correctly the practice of the authorities on this point, the action of the assessor in question would not be supported by headquarters, seeing that there was no depreciation allowance in force until 1925–26. We suggest that our correspondent might point out that fact to the assessor, and if he still declines to make both allowances—which are obviously equitable—then that the full facts should be placed by letter before the Secretary, Inland Revenue, Somerset House, London.

Obsolescence Allowance for Car.

"A. B. C."—A touring car four-seater was bought in 1921 for £440 and sold in 1927 for £25. Depreciation (£41) was allowed for 1925–26 and £40 for 1926–27. A new car was bought from the same makers in 1927 for £265. What amount can be deducted for obsolescence?

*** The amount is the cost of a touring four-seater of the same make in 1927 less (£25+£41+£40=) £106. That amount should be regarded as a professional expense of the year 1927.

LETTERS, NOTES, ETC.

ETIOLOGY OF CANCER.

DR. A. T. BRAND (Driffield), referring to the letter by Dr. W. H. Fearis on Spengler's bacteriological theory of cancer (JOURNAL, February 12th, p. 305), protests against the term "theory" being used in connexion with the etiology of cancer, and asserts that the bacterial origin of this condition is a fact which was established by logical deduction long before it was proved by experiment and demonstration. He argues that the distribution of cancer through the entire vertebrate kingdom postulates a microbic origin, since a microbe can be the only possible universal agent, and he considers that the investigations of Dr. T. J. Glover (see *Epitome*, January 29th, para. 127) have defined this pleomorphic organism conclusively. He adds that Dr. Glover's work has been confirmed by Drs. Julian London and J. M. McCormack of Toronto and Dr. M. J. Scott of Montana, while Dr. J. Young of Edinburgh has independently isolated a pleomorphic organism from cancerous growths, and Dr. Gye of London has discovered a filter-passing organism from the same. Dr. Brand concludes that attempts to produce malignant disease by mechanical irritation are now obsolete and impossible, and that attention should be paid rather to the cancerous tissues themselves and to the cause of the natural or acquired immunity from this disease possessed by many people.

LABOUR AND THE PUERPERIUM COMPLICATED BY PNEUMONIA.

DR. L. MATHER (Lancaster) writes to record a case of severe complications during pregnancy and the puerperium with a satisfactory outcome. A woman, aged 32, the mother of three children, developed pleurisy and pneumonia in the later weeks of pregnancy. Labour started spontaneously and terminated naturally with the birth of a healthy male child, weighing 5 lb. 12 oz. For several days the woman was very ill, with extensive consolidation of the bases of both lungs, and, at the height of her illness, acute cholangitis supervened, with deep jaundice. The temperature fell to subnormal twenty-four hours later, resolution quickly followed in the consolidated lungs, and the jaundice gradually disappeared. The patient's convalescence was rapid and uninterrupted, and one month after her confinement she was apparently little the worse for her ordeal. The child also progressed favourably.

VOLUNTARY PULSE CONTROL.

DR. THOMAS LINDSAY (London, S.W.) refers to the statement that voluntary and conscious control of the radial pulse, though rare, is not unknown (*Epitome*, February 26th, 1927, para. 216), and calls attention to his description of aortic systolic murmurs (JOURNAL, May 13th, 1922, p. 759), when he wrote: "Many persons, by contracting their muscles, can obliterate the radial pulse." He adds that he can do this easily himself, and that his wife, while nursing during the war, frequently detected this ability in military patients.

LIFE ASSURANCE AND TUBERCULOSIS.

DR. ROBERT CARSWELL (Wandsworth, S.W.18) has sent us a letter suggesting that holders of a negative tuberculin test certificate should be accorded specially favourable terms for sickness and life assurance. "A negative test certificate, by which," Dr. Carswell continues, "I mean negative in the original sense of Koch, would at least indicate freedom from the risks of endogenous tuberculosis. Not only would this be an economically sound proposition from the insurance point of view, but the pressure of the insurance world in this direction would react favourably on the elimination of tuberculosis by promoting on the part of individuals a desire to belong to the 'tuberculosis-free herd.'"

*** We referred this suggestion to Mr. Ferris-Scott, F.C.A., who is Secretary of the Medical Insurance Agency, as well as Financial Secretary and Business Manager of the British Medical Association. He writes:

"I have no knowledge as to the practical value of the suggestion Dr. Carswell makes, but there has been a movement for some considerable time towards the establishment of a practice by which every person holding a life assurance policy should submit to a medical examination every year. Attempts of this nature have been made with varying success in America and at least one; tentatively, in England. The advantage to the assured person should be fairly obvious; the advantage to the assurance company is the possibility that illness discovered by this thorough examination whilst in its early stages might be arrested and the claims experience of the company concerned thereby benefited. In practice, however, it has not been proved that the cost of paying adequately for these medical examinations would be recouped, nor is it certain that the average person would be willing to submit to a periodical medical examination at the behest of the assurance company. I should not care to say whether Dr. Carswell's suggestion would be an economical proposition, and I think that he is optimistic in so regarding it until he has made some suggestion as to the extent of the specially favourable terms to be granted. It might be economically sound if the specially favourable terms are 1 or 5 per cent. and the fee for the certificate only a few shillings, but such a fee would not be remunerative to the medical examiner. The proposition would not be economically sound if the specially favourable terms were 25 or 50 per cent. and the fee £3 3s.

"There is a class of life assurance which starts at an early age. I believe it is arguable, but I think an assurance company would accept the proposition, that a child of 12 or 15 might receive a negative certificate and develop tuberculosis at some time between 25 and 35. If I am correct in supposing that a person might receive a negative certificate at one period of his life, either before or after an attack, then it seems obvious that the assurance policy would have to be determinable or could be altered at the option of the assurance company, and the security of the assured's position would be severely damaged and confidence in life assurance shaken."

CORRECTION.

THE price of Daukes's *Barrier Charts for Health Officers*, which was reviewed in the JOURNAL of March 5th (p. 432), is 3s. 6d.—not 2s. 6d., as stated in the footnote to the review.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 95.

THE SURGICAL TREATMENT OF PARALYSIS OF THE VOCAL CORD AND OF PARALYSIS OF THE DIAPHRAGM.*

BY

LIONEL COLLEDGE, M.B., B.CH.CAMB., F.R.C.S.,
SURGEON, EAR AND THROAT DEPARTMENT, ST. GEORGE'S HOSPITAL;
AND
SIR CHARLES BALLANCE, K.C.M.G., M.S., F.R.C.S.,
CONSULTING SURGEON, ST. THOMAS'S HOSPITAL.

(With Special Plate.)

I.—THE VOCAL CORDS.

EXPERIMENTS performed on the monkey and the dog show that end-to-end, or end-to-side, anastomosis of the recurrent laryngeal nerve to the phrenic nerve is successful in restoring, after a certain lapse of time, movements of abduction and adduction of the vocal cord comparable to those of the opposite or normally moving cord. After section of the recurrent laryngeal nerve the vocal cord assumes a typical cadaveric position and the inner border is concave and flaccid. After six or eight weeks from the date of the operation the inner border of the immobile cord becomes straight and tense. There is, in fact, a tension about the previously paralysed cord which had not been present before. Four months after the first experiment of recurrent laryngeal-phrenic end-to-end anastomosis was carried out both vocal cords were moving equally in tranquil respiration. Six months after the experiment was done the previously paralysed cord moved more strongly than the other, and seven months after the experiment there was excessive, almost violent, movement as compared with the vocal cord on the normal side. This result was hardly a surprise, because the nerve current required to cause contraction of one half of the muscle of the diaphragm must be considerably stronger than that required to energize the small intrinsic muscles of the larynx.

The best method of anastomosis of the recurrent laryngeal nerve to the phrenic nerve so as to obtain recovery of movement of the paralysed vocal cord in rhythm with the movement of the normal cord remains to be determined.

In certain experiments in the monkey the root of the phrenic nerve from the third cervical nerve, or the root of the phrenic nerve from the fourth cervical nerve, was united side-to-end to the recurrent laryngeal nerve; and in others the root was divided and united end-to-end to the divided recurrent laryngeal nerve. In other experiments the divided recurrent laryngeal nerve was united end-to-end to the proximal segment of the divided main trunk of the phrenic nerve; and in yet others the end of the divided recurrent laryngeal nerve was anastomosed end-to-side to a small lateral incision made in the side of the main trunk of the phrenic nerve.

In some cases the end-to-side anastomosis of the recurrent laryngeal nerve to a root of the phrenic nerve or to the main trunk of the phrenic nerve was effected by making a small longitudinal median incision into the part of the phrenic nerve selected for the site of anastomosis and attaching the cut end of the recurrent laryngeal nerve to it. The end-to-side operation is the operation of choice—that is, if there is sufficient length of the recurrent laryngeal nerve to bring across the carotid sheath to the side of the phrenic nerve without tension on the anastomosis. If, however, the available length of the recurrent laryngeal nerve is insufficient to reach the phrenic nerve, then the phrenic nerve must be divided and the proximal end brought across to meet the divided distal end of the recurrent laryngeal nerve. The actual method of anastomosis, whether by lateral incision or longitudinal median incision, did not seem to affect the final result. We believe, however, that the plan of lateral incision is the plan to adopt when end-to-side anastomosis is performed, as there is a definite and immediate approximation of divided nerve fibres. In such cases a partial or complete paralysis of one half of the diaphragm follows, but in a few weeks the paralysis passes away.

In man, therefore, the operation of choice is recurrent laryngeal-phrenic anastomosis, end-to-side, the lateral incision of the main trunk of the phrenic being carried out in order to obtain a raw surface of cut nerve fibres to which the distal end of the cut recurrent laryngeal nerve is attached.

This decision is based not only on the recurrent laryngeal-phrenic nerve anastomosis experiments, but on the results of a large number of experiments in which the two ends of a divided nerve were implanted at varying distances apart into the side of, or into median incisions in, a neighbouring nerve. These experiments have been reported,[1] and they seem to prove that the lateral incision method leads to more rapid and satisfactory recovery of the muscles supplied by the divided nerve than when its two ends are implanted into median longitudinal incisions made in the neighbouring nerve.

There is also no advantage in attaching the recurrent laryngeal nerve to one of the roots of the phrenic. When the root is divided and its proximal end sutured end-to-end to the recurrent laryngeal nerve the distal end of the root has sometimes been left without being joined to another nerve, and sometimes it has been joined end-to-end to the divided proximal end of the descendens noni nerve. In either case, even when the vocal cord muscles function again, there seems to be some delay in the recovery of normal contractions of the whole muscle of the diaphragm. It is curious to note that the quickest return of function of the vocal cord follows end-to-end anastomosis of the recurrent laryngeal to the proximal cut end of the main trunk of the phrenic nerve, and the most rapid recovery of the whole diaphragmatic muscle has followed end-to-end anastomosis of the distal cut end of the phrenic nerve to the proximal cut end of the descendens noni nerve. This latter result is in itself surprising, as we have not been able to obtain return of movement in the vocal cords during tranquil respiration by means of descendens noni-recurrent laryngeal end-to-end anastomosis. We do not suggest any explanation of this experimental finding.

There is another point about end-to-side recurrent laryngeal-phrenic anastomosis. In some cases there seems to be delay or arrest in the complete recovery of the movements of the vocal cord, or there may be delay in the complete recovery of the diaphragm, or there may be delay in the complete recovery of both vocal cord and diaphragm. The cause of these variations would seem to be that the nervous energy travelling through the phrenic nerve is overtaxed. While before the operation the nerve current of the phrenic nerve had to cause only contraction of one half of the diaphragm, after the operation it has now also to excite contraction in the intrinsic muscles of the larynx. In all departments of life the pursuit of two objectives may delay or hamper complete success in either or both of them. Napoleon wrote to his vacillating Admiral Villeneuve, "It seems to me your purpose is *not exclusive enough* for a great operation. You must correct this fault, for that is the art of great successes and of great operations." This famous maxim is true not only of the great operations of war but also of those of surgery.

Nevertheless the success which has followed the end-to-side anastomosis experiments makes it clear that this is the best operation to perform. (Fig. 19.) The experiments in which more than one anastomosis was carried out are less likely (except in special circumstances, as when there is only a short piece of the recurrent laryngeal nerve available) to find a permanent place in surgical practice. The best recommendation of recurrent laryngeal-phrenic end-to-side anastomosis is that it is a simple procedure and is frequently followed by the best functional results.

The number of experimental anastomoses of the recurrent laryngeal nerve to other nerves done is 33: 6 anastomoses to the vagus nerve end-to-side, 7 anastomoses to the descendens noni nerve end-to-end, and 20 anastomoses to a root or the main trunk of the phrenic nerve. The end-to-end anastomosis with the main trunk of the phrenic nerve

* The experiments mentioned in this paper were carried out at the National Research Institute, Hampstead. The Medical Research Council paid the expenses and gave me every assistance. I am greatly indebted to Dr. Dale.—C.B.

The microscopical sections have been cut and stained by Mr. Steward at the Royal College of Surgeons by the kind permission of Sir Arthur Keith.

produced an unnaturally wide abduction movement of the cord, while the end-to-side anastomosis to the phrenic nerve was followed by an abduction movement comparable to that of the opposite or normal cord in tranquil respiration.

The attachment of the divided end of the recurrent laryngeal nerve to a root of the phrenic nerve instead of to the main trunk does not appear to present any advantage. When one root of the phrenic nerve was divided a portion of the corresponding half of the diaphragm was paralysed, but in one experiment there was complete recovery from this after some months, following the attachment of the proximal end of the divided descendens noni nerve to the distal end of the root of the phrenic nerve. It will be seen in the second part of this paper that paralysis of one half of the diaphragm is under the control of the surgeon and that this paralysis need no longer be of serious concern to the operator.

In the hussar monkey the microscope shows that the root of the phrenic from the third cervical nerve is composed of many fine presumably motor fibres and some large fibres, while the root from the fourth nerve contains many large as well as small fibres. A large number of microscopic sections of the nerves of the neck of man and the monkey have been examined, and large and small nerve fibres in varying proportion have been seen in all the nerves. (Figs. 1 to 4.) In the microscopic sections of the superior laryngeal nerve and of its internal and external branches there appears to be a marked difference in size between the nerve fibres (sensory) of the internal branch and the nerve fibres (motor) of the external branch. It has not been possible, however, to follow this distinction with any certainty in the case of the other nerves. All so-called motor nerves contain large nerve fibres, but whether these are motor or sensory it is not possible to tell.

DESCRIPTION OF SPECIAL PLATE.

(FIGS. 1 TO 4.)

FIG. 1.—Transverse section of the phrenic nerve of the hussar monkey. (× 50.) The large nerve bundle comes from the fourth cervical nerve. The next largest bundle comes from the third cervical nerve. The smallest nerve is presumably the root from the fifth cervical nerve, but this root was not seen during the dissection. The nerve bundle arising from the fourth cervical nerve contains much larger fibres than the nerve bundle from the third cervical nerve. This difference in the size of the nerve fibres may indicate some difference in function.

In man the roots of the third and fourth cervical nerves can be seen to join a little below the point where the root from the fourth cervical nerve is given off. They are enclosed in one sheath beneath the fascia of the scalenus anticus muscle, but can be seen to continue as separate nerves on the way down the neck. So clearly separate are the two roots of the phrenic that a lateralized tenotomy knife can be passed between them and either nerve can be divided without injury to the other. This anatomical fact was taken advantage of in the experiment on a hussar monkey in which the separation of the two roots was observed. In this monkey the root from the fourth cervical nerve was divided with a tenotomy knife as described and united end-to-end with the divided recurrent laryngeal nerve. The difference in size of the nerve fibres of the different roots as observed in the hussar monkey is not seen in the phrenic of man.

FIG. 2.—Transverse section of the superior laryngeal nerve in a man aged 40. (× 30.) The main trunk is divided into one large bundle of fibres and four smaller ones. The fibres of the large bundle are much larger than those of the small bundles.

FIG. 3.—Transverse section of the internal branch of the superior laryngeal nerve. (× 30.) The drawing shows three bundles of fibres. The fibres in the large bundle are all of comparatively large size. It would appear that in the superior laryngeal nerve the large fibres are sensory and the smaller ones motor in function.

FIG. 4.—Transverse section of the external branch of the superior laryngeal nerve. (× 50.) The drawing shows four bundles of fibres. The fibres are small except a few large ones scattered among the masses of small fibres.

The operation of recurrent laryngeal-phrenic anastomosis end-to-side (by lateral incision of the main trunk of the phrenic nerve) has been performed by one of us in the case of a woman, aged 54, who eight months before the anastomosis operations suffered from paralysis of both vocal cords following an operation for removal of a thyroid tumour. Five months after the anastomosis operation on the right side and four months after the anastomosis operation on the left side were carried out both cords of the patient were showing slight abduction excursions in tranquil respiration, and the paralysis of both halves of the diaphragm had completely disappeared.

Experiments had been performed before the recurrent laryngeal-phrenic anastomosis was attempted. In these the vagus nerve and the descendens noni nerve were united to the divided recurrent laryngeal nerve. In the end-to-side recurrent laryngeal-vagus anastomoses and the end-to-end recurrent laryngeal-descendens noni experiments, the vocal cord in each case recovered its tension, and its inner border became straight, but no movement of abduction was observed in tranquil respiration some eighteen months after the operation. This movement, however, was obtained by partially asphyxiating the animal while it was under ether by pressure on the trachea. The inspiratory effort on releasing the pressure on the trachea became so powerful that the muscles of the immobile vocal cord recovered sufficient nervous energy to contract. In one case, four and a half months after descendens noni-recurrent laryngeal anastomosis, the monkey was placed under ether and pressure was made on the trachea. This induced strong adduction of both vocal cords. As soon as the pressure which had induced partial asphyxia was relaxed, wide outward excursions of both vocal cords, equal on the two sides, were observed and continued for two or three minutes. The excursions of the previously immobile cord gradually diminished in extent as the asphyxia passed off, and then ceased.

This experiment (originally suggested by Professor Starling) possibly gives the key to the problem of re-education in man of the paralysed vocal cord after anastomosing the recurrent laryngeal nerve to the phrenic nerve. "Holding the breath" is necessarily followed in man by a strong inspiratory effort, which would probably cause in man, as in the monkey experiment, abduction of the previously immobile vocal cord, so that a patient's immobile or slightly moving cord might at last be re-educated to act in an harmonious subconscious normal respiratory movement with the vocal cord of the opposite or healthy side.

This method of re-education—"holding the breath"—is being employed in the case of the woman mentioned above, and in addition a galvanic current has been passed across the larynx for ten minutes once or twice a day since the operation, in the hope that it would influence the recovery of the intrinsic muscles of the larynx and perhaps prevent the scar tissue of the operations from causing undue pressure on the nerves and the anastomoses.

That a nervous impulse could pass through the anastomoses made between the recurrent laryngeal nerve and the vagus and descendens noni nerves was clear from the following experiments.

1. Fifty days after a descendens noni-recurrent laryngeal anastomosis was done in a monkey the wound was opened and the anastomosis exposed. On stimulating (1) the hypoglossal nerve proximal to the origin of the descendens noni nerve, (2) the descendens noni, (3) the site of the anastomosis, the vocal cord was seen to abduct.

2. Seven months after a recurrent laryngeal-vagus anastomosis was done in a monkey the wound was opened. The vagus was stimulated (1) proximal to the anastomosis, and (2) at the site of anastomosis. The vocal cord was seen to abduct.

These stimulations caused abduction of the previously immobile cord; the excursions of the cord were not so wide as on the opposite or healthy side. Later (when perhaps the abductor was tired) strong adduction was observed.

The recognition of the certainty of recovery of the movements of the vocal cord which follows recurrent laryngeal-phrenic anastomosis made us abandon the operation of uniting the recurrent laryngeal nerve with either the descendens noni nerve or the vagus nerves. The object in view is not merely to obtain a return of tone in the cord, however desirable this may be, but to win by means of operation a recovery of the movements of adduction and abduction equal and synchronous with the movements of the opposite or normal cord.

From the experience gained from the monkey experiments it is not possible to state at what period after the experimental operations movement of the recovering cord first occurs. The animals have to be kept for nerve anastomosis experiments to mature for long periods of time. They are valuable and scarce, and an anaesthetic is dangerous.

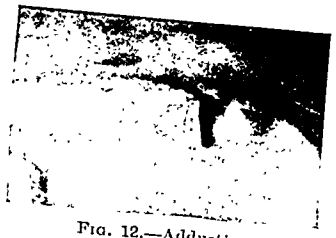

FIG. 12.—Adduction.

FIG. 13.—Abduction.

In man, however, when these operations become performed generally it will be possible to note week by week, by the aid of the laryngoscope, the slow but certain stages of recovery of movement of the vocal cord. It appears from the experiments, however, that the movement of adduction reappears earlier than that of abduction, and this corresponds with the familiar clinical experience that the abductors of the cords are more vulnerable than the adductors. The adductors, too, correspond to the flexor muscles of the limbs, and it is a common experience that after a nerve lesion of a limb the flexor muscles recover before the extensors. Negus points out that in evolution "adduction is an older function than abduction; therefore the power of the former survives that of the latter."

In disease, and possibly in injury, one intrinsic muscle of the larynx may atrophy though its nervous supply is intact, while the other intrinsics are acting normally. Hughlings Jackson and Morell Mackenzie published a case in 1865.[2] The abductor muscles were found greatly atrophied after death, while the nerve structures were intact. It would appear also that bilateral paralysis of the abductor muscles may arise from disease of the nerve fibres distributed to these muscles without paralysis of the other intrinsic muscles of the larynx.[3] In our experiments when perfect functional recovery is not present these facts should be remembered. It may be that some intrinsic muscle or some nerve filaments have not regenerated so well as others. This demonstrates the necessity, at a later stage of the experiments, for the careful study of microscopical sections of each intrinsic muscle and of its motor nerve fibres.

In the experiments the recurrent laryngeal nerve has always been completely divided, and as a result the vocal cord occupies the cadaveric position; but in cases of abductor paralysis in man the paralysed cord lies nearer to the mid-line than the cadaveric position because of tonic contraction of the adductor muscles.

Another question also requires an answer: When the vocal cord is moving normally through nervous impulses conveyed to it through the phrenic nerve, will the patient be able to phonate? This is the question asked by the late Sir Frederick Mott. The answer can hardly be decided by experiments on the monkey; operation on man will give the reply This is the decisive experiment. Sir Frederick Mott pointed out that the lemur monkey of the forests of Sumatra possessed a highly developed larynx, and that these animals were said to sing in chorus in their native wilds. He suggested that one of these monkeys should be obtained, as it would be very important to know whether, after a recurrent laryngeal-phrenic anastomosis had been performed, the singing voice would return or be modified; but it has not been possible to obtain a lemur monkey.

The recovery of the movement of the vocal cords after recurrent laryngeal-phrenic anastomosis has been filmed, and the appearances are described in another part of the paper.

It is not possible to say how long after paralysis of the vocal cord has taken place it would be justifiable to attempt to restore the movement of the cord by surgical operation. The surgical treatment of paralysis of the face may be attempted as long as contraction of the muscles of the face, however feeble—if necessary under an anaesthetic—can be obtained by stimulation through the skin with the galvanic current. It does not appear whether this method has been employed in the case of the intrinsic muscles of the larynx, but an electrode might be introduced into the larynx through the laryngoscope and a galvanic current used in order to find out whether any movement of the paralysed vocal cord can be induced. Frazier and Chevalier Jackson have advised that mobility of the crico-arytenoid joint should be tested with a long probe, lest the cartilages have become fixed either from arthritis or from secondary changes in the joint following prolonged paralysis and interference with its nerve supply.

There is another point of contrast also: in paralysis of the face some treatment, perhaps intermittent, such as massage and galvanism, has almost always been adopted to maintain the nutrition of the muscular fibres; so that, years after a complete palsy of the face has occurred, nerve anastomosis may be followed by a wonderful recovery of the facial muscles. The fact that, in the case of the patient previously quoted, eight months elapsed between the injury to the recurrent laryngeal nerves and the anastomosing nerve operations, and that already there is promise of a successful result, is a hopeful augury for the performance of the operation when the paralysis has continued for a much longer period than eight months.

Two experiments have been performed in which the recurrent laryngeal nerve was divided three months and six months before it was united to the phrenic nerve, but the specimens from these cases are not yet ready for publication. (Figs. 5 and 6.)

Altogether twenty experiments have been performed in which the recurrent laryngeal nerve has been anastomosed in various ways to a root of the phrenic nerve or to the main trunk of the phrenic nerve, and the results leave no question in the mind as to the success of the operation. When both recurrent laryngeal nerves have been anastomosed to the corresponding phrenic nerves the result is not always at first satisfactory. In a large rhesus monkey in which the operations on the two sides of the neck were separated by a long interval of time no stridor and no difficulty of breathing occurred; but in two baboons and two dogs it was noticed that while in tranquil respiration there was no stridor, yet when these animals became excited noisy respiration occurred. In these baboons and dogs it must be noted that the central nervous connexion of both recurrent laryngeal nerves and both phrenic nerves had been disturbed—the recurrent laryngeal nerves being united to the proximal part of the divided phrenic nerves and the distal part of the phrenic nerves to the divided proximal parts of the descendens noni nerves. Further, the depressor muscles of the larynx in the baboons were paralysed for a time, the distal segment of the descendens noni nerve on each side of the neck being united end-to-side to the lower border of the hypoglossal nerve, and in some other cases to the side of the phrenic nerve proximal to the recurrent

DESCRIPTION OF SPECIAL PLATE.

(FIGS. 5 TO 13.)

FIG. 5.—Microscopic appearance of phrenic nerve of a baboon distal to a descendens noni-phrenic anastomosis eighteen months after the performance of the anastomosis. (× 150.) Cajal stain.

FIG. 6.—Microscopical appearance of recurrent laryngeal nerve of a baboon distal to a recurrent laryngeal-phrenic anastomosis eighteen months after the performance of the anastomosis. (× 150.) Cajal stain. The recurrent laryngeal nerve had been divided in the lower part of the neck six months before the anastomosis operation was done.

FIG. 7.—Dog. Photographs by Mr. Melville of the position of the diaphragm at the end of expiration and at the end of inspiration (Experiment I). A, End of expiration. B, End of inspiration. Twenty seconds elapsed between the two exposures. Each exposure lasted an eighth of a second. Both halves of the diaphragm are contracting through nerve currents passing through the descendens noni-phrenic anastomosis.

FIGS. 8 AND 9.—Dog under ether anaesthesia (Experiment I). Rapid respiration described by Richet by the name "polypnoea." Stated by Semon and Horsley as occurring when the lower third of the cortex of the precrucial gyrus is stimulated. The rapid respiration is frequently observed during ether anaesthesia in this animal and is relieved by the administration of a little chloroform. Note the wider space between the arytenoid cartilages in abduction. *The film was taken fifteen months* after a recurrent laryngeal-phrenic end-to-end anastomosis was performed on the right side, and ten months after the recurrent laryngeal-phrenic end-to-end anastomosis was done on the left side. In this case the main trunk of the phrenic was used for the end-to-end anastomosis on the left side, while on the right side the end-to-end anastomosis was made to the proximal segment of the root of the phrenic arising from the sixth cervical nerve. (See also Figs. 14 and 15.)

FIGS. 10 AND 11.—Large rhesus monkey; tranquil respiration (Experiment II). Note the wide angle formed by the two sides of the arytenoids in abduction and the lesser angle in adduction. These photographs do not give the same effect as seen in the film. For example, in the film much more adduction is visible; the channel between the vocal cord approximates to a slit-like opening. The film was taken two years and six months after the operation of recurrent laryngeal-phrenic end-to-side anastomosis was performed on the right side, and thirteen months after the operation of recurrent laryngeal-phrenic anastomosis end-to-end was done on the *left side*. Note the wider abduction movement of the vocal cord on the left side. (See also Figs. 16 and 17.)

FIG. 12.—Same monkey. Strong adduction during partial asphyxiation. The cords have nearly passed off the field.

FIG. 13.—Same monkey. Wide abduction following immediately after pressure on trachea was relaxed.

laryngeal-phrenic end-to-end anastomosis. It is true that operations on the two sides of the neck were separated by a considerable length of time, but now, when both cords were moving, when both halves of the diaphragm had recovered from paralysis, and when the muscles on both sides of the neck were again working normally, why is it that noisy respiration on excitement occurs? It must be remembered that the muscles innervated by the recurrent laryngeal, phrenic, and descendens noni nerves are intimately associated in the respiratory movements. The noisy respiration caused by the inco-ordination of muscular movement does not appear surprising, since complicated nerve arrangements must be made in the central nervous system before the nerve-cells of the central connexions of the phrenic and descendens noni nerves are brought into nervous union with those nerve cells which control under normal circumstances the rhythmical respiratory movements of the vocal cords and each half of the diaphragm. Time alone offers the probability or possibility of complete recovery.

The end-to-side and end-to-end anastomoses of the distal end of the divided recurrent laryngeal nerve to the main trunk of the phrenic nerve on one side of the neck have been invariably successful, in that they are followed by apparently normal movements of the corresponding vocal cord; but when such an operation has been carried out on both sides of the neck, the movements of the vocal cords, thus energized through union with the corresponding phrenic nerves, have shown in a few instances an inco-ordination or false timing of the movements of the vocal cords, indicating that though the respiratory centre is working yet it has not regained normal control. This paradoxical result affects the vocal cord on the side which was first operated on, though previous to the second operation this vocal cord was moving equally and synchronously with the opposite or normally moving vocal cord.

There are other points to consider. The end-to-end suture of the extremely fine nerves in the monkey is not in all cases carried out so perfectly as is desirable; and again, the presence of scar tissue at the site of anastomosis may possibly delay or weaken the passage of a nervous impulse. These, no doubt, are theoretical considerations, but the fact remains that when both recurrent laryngeal nerves have been anastomosed end-to-end to the corresponding phrenic nerves a paradoxical movement of the vocal cords has been seen, adduction occurring in inspiration and abduction in expiration.

Inco-ordination is also seen in emotional movement, such as laughing, after a nerve anastomosis has been performed for facial palsy. The distortion of the face may be so great that, superficially observed, it appears that no recovery has taken place; but if and when by re-education both sides of the face work together the distortion on emotional movement does not occur. It may be that in the practical application of the operation for double abductor paralysis the difficulty of inco-ordination may be avoided or minimized by performing the operation on one side only, leaving the opposite cord without movement, since it is a commonplace observation that unilateral paralysis frequently causes neither dyspnœa nor lasting alteration in the voice.

In Blalock and Crowe's paper[4] admirable figures are given of regeneration of the recurrent laryngeal nerve distal to anastomosis with the descendens noni nerve and the vagus nerve. This regeneration we have found whatever cervical nerve has been anastomosed to the recurrent laryngeal nerve. In our experiments in no instance could the recovery of the movements of the vocal cord be compared to that obtained by anastomosis of the recurrent laryngeal nerve to the phrenic nerve. In our experiments, too, monkeys were chiefly used, and in Blalock and Crowe's dogs only. We think the experiments with the monkey give results which are of more service for comparison when the time arrives for their application to the surgery of man. Blalock and Crowe recommend the selection of the descendens noni nerve or the upper root of the phrenic. They say that the best results are obtained by making the anastomosis close to the larynx, as the axis cylinders have a shorter distance to traverse before reaching the end-organs in the intrinsic laryngeal muscles; but this is a theoretical statement, and represents a theory of nerve regeneration which is not universally accepted (see *Healing of Nerves*, Ballance and Stewart).

Blalock and Crowe state that the entire severance of the phrenic or vagus involves a needless risk. No one has suggested the entire severance of the vagus, and in man we only recommend the division of the trunk of the phrenic when there is not a sufficient length of recurrent laryngeal nerve to bring across the carotid sheath in order to carry out an end-to-side anastomosis. We do not believe in risk associated with division of the phrenic on one side (it is often destroyed at the present time in the treatment of some forms of phthisis and bronchiectasis), and we know that the anastomosis of the proximal end of the divided descendens noni nerve to the distal cut end of the phrenic will eventually result in complete recovery from paralysis of the diaphragm. We have employed end-to-end and end-to-side anastomosis of the recurrent laryngeal nerve to the upper and middle phrenic roots, but we are convinced that end-to-side anastomosis of the recurrent laryngeal to the trunk of the phrenic is the operation of choice. Further, our experiments teach us that operation on one of the phrenic roots does cause a partial paralysis of the diaphragm. We agree, however, with these authors that light ether anæsthesia is of great importance in observing the movements of the vocal cords; deep anæsthesia or morphine may abolish the movements and lead to wrong conclusions. This point was insisted on also by Semon and Horsley.

DESCRIPTIONS OF EXPERIMENTS.

In each experiment before the sutures were passed to bring the cut ends of the several nerves together the recurrent laryngeal and phrenic nerves were stimulated with the faradic current. The contraction of one half of the diaphragm was easily observed, and so was the movement of the corresponding vocal cord, by means of the laryngoscope. It was noted, too, that the contraction of the muscle of one half of the diaphragm was sometimes associated with contraction of the lower intercostal muscles. These latter muscles being associated in normal respiratory action with the muscle of the diaphragm seem to have received a reflex hint to carry on as normal.

It has been already said that twenty experiments in which the recurrent laryngeal nerve was united to the phrenic nerve have been performed. When both recurrent laryngeal nerves were anastomosed to the corresponding phrenic nerves the two operations were counted in the above list as two experiments. In the following description of certain of these experiments when two operations have been done on the same animal it has been found more convenient to reckon such a procedure not as two experiments but as one.

EXPERIMENT I.—*Dog.*

This animal was constantly barking, which was a fact of value in relation to the nature of the experiment proposed to be performed. The dog was deeply anæsthetized with ether, but unfortunately just before the film was about to be taken the respiration became very rapid, shallow, and panting. The film therefore shows much smaller excursions of the cords than have been observed to take place when the respiration is quiet and natural. The right cord, however, will be seen to have a wider abduction movement than the left, and this is probably due to the fact that the operation on the right side of the neck was performed *five months* before that on the left side. The film was taken fifteen months after the operation was done on the *right side of* the neck and ten months after the operation was done on the left side of the neck. (See Figs. 8 and 9.)

First Operation (*Right Side*).—Recurrent laryngeal nerve to the proximal segment of the root of the phrenic derived from the sixth cervical nerve—anastomosis end-to-end. Descendens noni nerve to the distal segment of the root of the phrenic derived from the sixth cervical nerve—anastomosis end-to-end. (*Fig.* 14.)

In this case it will be seen that the root of the phrenic from the sixth cervical nerve was used for the anastomoses and not the main trunk of the nerve.

The animal began barking again vigorously three months after the operation, and five months after the operation the right cord was moving synchronously and equally with the *normal* cord on the left side.

It was decided to do a similar operation on the left side.

Second Operation (*Left Side*).—Recurrent laryngeal-phrenic (main trunk) anastomosis, end-to-end. Descendens noni-phrenic (main trunk) anastomosis, end-to-end. (*Fig.* 15.)

Thus on the left side of the neck a different operation was done from that carried out on the right side of the neck. The recurrent laryngeal nerve and the main trunk of the phrenic nerve were divided and the proximal end of the divided phrenic was united end-to-end with the distal cut end of the divided recurrent laryngeal nerve. The descendens noni nerve was divided in the *operation on the right and left sides* of the neck, below the

origin of the branches to the omo-hyoid, sterno-hyoid, and sterno-thyroid muscles, and its proximal end united to the distal end of the divided root or main trunk of the phrenic nerve.

Six months after the operation on the left side of the neck the dog was barking again loudly, but perhaps the bark was not exactly the same as before the operations; the movements of both cords were equal and synchronous.

Examination of the State of the Diaphragm (at University College).—A film of the contractions of the diaphragm cannot at present be taken, but Mr. Melville hopes that before long this may be possible. Professor Elliot Smith's report is as follows:

The first examination was made with the radiographic screen ten months after the operation was done on the right side of the neck and five months after the operation was done on the left side of the neck.

Report on the Right Side.—The major part of the right half of the diaphragm is contracting normally, especially the posterior portion; but an area of the muscle is still paralysed.

Report on the Left Side.—Active contraction of all parts of the muscle.

Five months later another examination was made. The report stated that both halves of the diaphragm were actively contracting, and there was no sign of paralysis on the right side. (Fig. 7.)

Ten months after the second operation was done the vocal cords were moving equally and synchronously as seen through the laryngoscope. At this time the movements of the vocal cords were filmed. The film shows that the excursions of the right vocal cord were slightly more pronounced than those of the left vocal cord.

Some little time after the filming of the vocal cords it was noted that the dog was suffering from stridor and that the bark was very hoarse. The animal was not under constant observation as it was kept at the farm laboratories. It seemed that the stridor and hoarseness might be accounted for either by the prolonged anaesthesia necessary for the filming upsetting the respiratory rhythm, especially as multiple anastomoses had been done, or possibly that the extension of the neck during the filming had stretched or in some way damaged the anastomoses. The larynx of the dog was examined again, when, though the vocal cords were actively moving, adduction was seen to take place in inspiration and abduction in expiration. All observers note that the movements of the vocal cords are very sensitive to deep anaesthesia.

Three months after the filming of the vocal cords the dog was anaesthetized again, and killed with ether at the close of the examination.

There was still the paradoxical movement of the vocal cords as described above, but adduction was accompanied by movement of the larynx as a whole, caused by the subhyoid muscles, so that possibly the adduction may have been due to extrinsic influence and not caused simply by contraction of the intrinsic muscles.

The following experiments seem, however, to point to a different conclusion.

1. Stimulation of the undivided recurrent laryngeal nerve on the left side was followed by adduction of both vocal cords.

2. Stimulation of the distal end of the divided recurrent laryngeal nerve was followed by adduction of both vocal cords.

3. Stimulation of the proximal end of the divided nerve was followed by adduction of the opposite vocal cord.

The two last observations are paradoxical and contrary to what occurs in normal circumstances, so that the truth seems to be that the prolonged anaesthesia required for the filming of the vocal cords had interfered with their normal rhythm of movement.

The appropriate area of the cortex cerebri was stimulated, but no movement of the vocal cords was seen; when the cortical stimulation was done the animal had been under deep anaesthesia for some time.

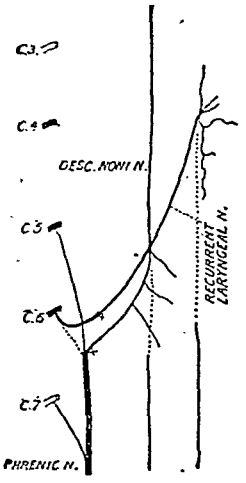

FIG. 14.—Dog (Experiment I). Recurrent laryngeal-phrenic (root from sixth cervical nerve) end-to-end anastomosis. Descendens noni-phrenic (distal end of divided root from sixth cervical nerve) end-to-end anastomosis.

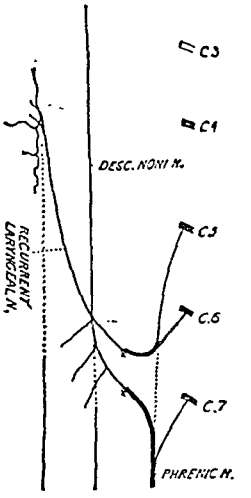

FIG. 15.—Dog (Experiment I). Recurrent laryngeal-phrenic (main trunk) end-to-end anastomosis. Descendens noni-phrenic end-to-end anastomosis.

EXPERIMENT II.—*Large Rhesus Monkey.*

First Operation (Right Side).—Recurrent laryngeal-phrenic anastomosis, end-to-side. The recurrent laryngeal nerve was divided and the distal cut end united, end-to-side, to a small median incision made in the main trunk of the phrenic nerve. (Fig. 16.)

Six months later the right cord was moving synchronously with the left.

Second Operation (Left Side).—Seventeen months after the operation on the right side the following operation was performed on the left side: Recurrent laryngeal-phrenic (main trunk) anastomosis, end-to-end. No anastomosis of distal end of phrenic to any other nerve. (Fig. 17.)

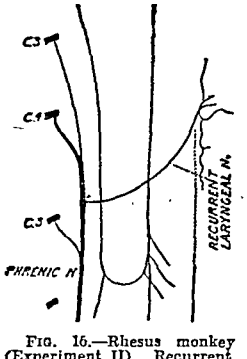

FIG. 16.—Rhesus monkey (Experiment II). Recurrent laryngeal-phrenic anastomosis, end-to-side. (Small median incision made in middle of phrenic trunk.)

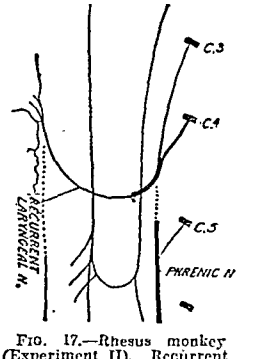

FIG. 17.—Rhesus monkey (Experiment II). Recurrent laryngeal-phrenic end-to-end anastomosis. No anastomosis of distal part of phrenic to any other nerve.

Six months later both cords were moving well, but the left cord (the recurrent laryngeal had been attached to the whole phrenic) showed a wider abduction excursion than the left.

The Diaphragm.—Examination at University College with the radiographic screen by Professo. Elliot Smith, Dr. Beattie, and Mr. Melville, two years and five months after the operation on the right side and twelve months after the operation on the left side. The report on the right side stated that all parts of the diaphragm were contracting equally and well. That on the left side was as follows: "No contraction of any part of left half of diaphragm; cupola moves passively upwards and downwards with respiration."

This monkey is still alive and well. It is three years since the recurrent laryngeal-phrenic anastomosis was done on the right side and one and a half years since the recurrent laryngeal-phrenic anastomosis was performed on the left side. This animal has never had any stridor. Both vocal cords are apparently moving naturally. It is to be noted that, though the left half of the diaphragm is paralysed, the right half is contracting through nervous influences passing in the normal manner through the right phrenic nerve—a recurrent laryngeal-phrenic end-to-side anastomosis having been done. (Figs. 10 to 13.)

EXPERIMENT III.—*Baboon.*

Operation (Right Side).—Recurrent laryngeal-phrenic end-to-end anastomosis. Descendens noni (proximal end)-phrenic (distal end) end-to-end anastomosis. Descendens noni (distal end)-hypoglossal end-to-side anastomosis. (Fig. 18.)

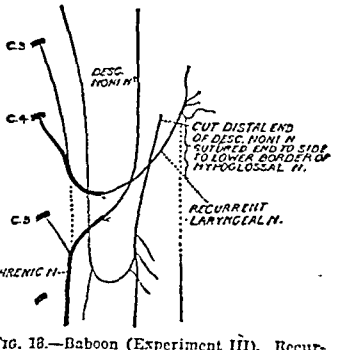

FIG. 18.—Baboon (Experiment III). Recurrent laryngeal-phrenic end-to-end anastomosis. Descendens noni-phrenic end-to-end anastomosis. Descendens noni-hypoglossal end-to-side anastomosis

A. *The Vocal Cords.*—Four months afterwards: Right vocal cord moves equally with left in tranquil respiration. Six months after operation: Right vocal cord moves more strongly than left. Seven months after operation: Right vocal cord moves excessively as compared with the movements of the left vocal cord; the movements of the cords are, however, synchronous. (Observed by Sir David Ferrier and the late Sir Frederick Mott.)

B. *The Diaphragm.*—Examination by Dr. Eidinow with the radiographic screen at the Hampstead Institute seven months after

the operation. The report stated that both halves of the diaphragm contracted equally and normally. (Professor Leonard Hill agreed with this report.)

C. *The Depressor Muscles of the Hyoid Bone and Larynx.*—Seven months after operation: The muscles on the right side of the neck react to the faradic current in a normal way and like those on the left side of the neck.

The baboon became ill two weeks later and was destroyed by ether inhalation.

EXPERIMENT IV.—*Dog.*

First Operation (*Right Side*).—Recurrent laryngeal-phrenic (main trunk) end-to-end anastomosis. Descendens noni-phrenic (main trunk) end-to-end anastomosis.

Three months later the animal was running about in good health; there was no sign of difficulty in breathing.

Six months after the operation: Both cords move equally and synchronously. Perhaps there is not quite so much abduction of the right cord as there is of the left cord. The adduction movement of both cords is strong.

The wound was opened and the hypoglossal nerve proximal to the origin of the descendens noni nerve and the descendens noni nerve proximal to its anastomosis with the phrenic nerve were exposed and stimulated with the faradic current. Contraction of the right half of the diaphragm occurred and continued rather violently for a short time after the faradic stimulation ceased. Previous to this experiment no difference could be detected on inspection and palpation between the movements of the upper half of the right abdominal wall and ribs and the movement of the corresponding parts on the left side.

Second Operation (*Left Side*)—six months after operation on the right side.—Recurrent laryngeal (main trunk) -phrenic end-to-end anastomosis. Descendens noni-phrenic (main trunk) end-to-end anastomosis.

Nine months after the second operation: Some stridor had been noted for two or three months when the animal was excited.

Vocal Cords.—Both cords abduct, but the right moves more actively than the left. Adduction, which is a strong movement on both sides, takes place in inspiration and abduction in expiration.

Diaphragm.—Examination by Professor Elliot Smith at University College. The right side showed normal diaphragmatic contraction; all the muscle was acting. On the left side the movement appeared to be less in amplitude than that on the right. It seemed that some of the muscle fibres on the ventral surface were not yet active.

Two months after the examination at University College the animal was killed by the inhalation of chloroform. Before death took place both recurrent laryngeal nerves were exposed near the larynx and stimulated with the faradic current. Stimulation of the right recurrent laryngeal nerve with a moderate faradic current caused strong adduction of *both* cords. When the stimulation ceased the cords moved outwards, leaving a wide air space. Stimulation of the left recurrent laryngeal nerve gave the same result, but the movement on the right side was stronger than that on the left.

The paradoxical movement of the vocal cords is discussed in another part of the paper. In normal circumstances the stimulation of the intact recurrent laryngeal nerve is followed by an equal movement of both vocal cords. It is interesting that the same result obtained in this case, though each recurrent laryngeal nerve had been anastomosed to the corresponding phrenic nerve. Both halves of the diaphragm were contracting through nerve currents passing through the descendens noni-phrenic anastomoses, but the left muscle of the diaphragm had not completely recovered.

EXPERIMENT V.—*Dog.*

First Operation (*Right Side*).—Recurrent laryngeal-phrenic (main trunk) end-to-end anastomosis. Descendens noni-phrenic (main trunk) end-to-end anastomosis. Only one root (that from the sixth cervical nerve) was observed at the operation.

Seven months later the right vocal cord moved synchronously with the left vocal cord, but the abduction excursion on the right side was slightly more marked than the same movement on the left side. The abdominal wall and ribs moved on the right side in the same manner as those on the left side, showing there was no paralysis of the diaphragm.

Second Operation (*Left Side*)—eight months after first operation.—Recurrent laryngeal-phrenic (main trunk) end-to-end anastomosis. Descendens noni-phrenic (main trunk) end-to-end anastomosis.

Three months later there was no stridor or other evidence of difficulty of breathing.

Four months after the second operation the animal died of acute lobar pneumonia.

The microscopic sections of the nerves and intrinsic muscle of the larynx have not yet been studied. They will form the basis of another paper.

EXPERIMENT VI.—*Dog.*

Operation (*Right Side*).—Recurrent laryngeal-phrenic end-to-side anastomosis. The end of the recurrent laryngeal nerve was sutured to a small transverse incision made in the side of the trunk of the phrenic nerve formed by the union of the roots from the fifth and sixth cervical nerves.

Two months after operation the animal was barking again.

Three months after operation the right vocal cord was straight, tension good. Slight abduction was observed during tranquil respiration. The barking of this dog had become a nuisance.

Seven months after operation the right vocal cord moved actively, equally, and synchronously with the left vocal cord.

Diaphragm.—Examination at University College with the radiographic screen by Professor Elliot Smith and Mr. Melville, who reported: "Both halves of the diaphragm contracting equally and normally." A few weeks previously, at another examination, the report was as follows: "Both halves of diaphragm contracting well. Right half is contracting well and as a whole, but a small area near the vena cava seems to be lagging behind the rest."

EXPERIMENT VII.—*Hussar Monkey.*

Operation (*Left Side*).—Recurrent laryngeal-phrenic end-to-side anastomosis. The anastomosis was made by the method of lateral incision. (Fig. 19.) The phrenic nerve was seen to be formed of two bundles of nerves. A fine tenotomy knife was passed between them and made to divide one of the bundles. Into the gap thus made the cut end of the recurrent laryngeal was fixed by one suture of the finest catgut. The two nerve bundles of the phrenic nerve came respectively from the third and fourth cervical nerve. That from the fourth cervical nerve was the larger, and it was this bundle which was divided; so the anastomosis was between the fourth cervical root of the phrenic and the recurrent laryngeal nerve. Whether the healing process spread the anastomosis to the root from the third cervical nerve or whether the anastomosis remained a pure recurrent laryngeal-phrenic (fourth root) junction is not known.

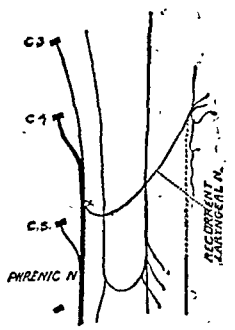

FIG. 19.—Hussar monkey (Experiment VII). Recurrent laryngeal-phrenic end-to-side anastomosis. The anastomosis was done by the method of lateral incision of the phrenic nerve.

Three months after the operation Dr. Eidinow examined the diaphragm with the radiographic screen. *Report:* Left half of diaphragm contracting normally. (Professor Leonard Hill concurred in the report.)

Six months after the operation the vocal cords were examined. *Report:* Deep anaesthesia: shallow breathing. The glottis in this animal is normally widely open. It never moves in its large cage, and therefore the respiratory centre has the minimum amount of work to do. The left vocal cord is tense and straight, but immobile. There is scarcely any movement of the right vocal cord.

Nine months after the operation the normal position of *both* vocal cords seemed to be wide abduction. There was slight abduction of the left vocal cord. Strong adduction of both cords was caused by partial asphyxiation, which was followed by strong abduction, which was not so marked on the left side as on the right. Deep anaesthesia abolished the movement of both cords. Two weeks after this examination the animal died.

EXPERIMENT VIII.—*Large Barking Baboon.*

First Operation (*Right Side*).—Recurrent laryngeal-phrenic end-to-end anastomosis. Descendens noni-phrenic end-to-end anastomosis.

The recurrent laryngeal nerve had been divided three months before this operation. The distal end of the descendens noni nerve was not united end-to-side to the hypoglossal. During the operation the root from the third cervical nerve was not seen; the root from the fourth cervical nerve was comparatively large. It is not certain whether the trunk of the phrenic nerve formed by the junction of the third and fourth nerve roots was divided and employed in the anastomosis or whether only the root of the phrenic from the fourth cervical nerve was used. The laryngoscope showed the right vocal cord without tone, with a concave border and immobile. Before doing the anastomosis the recurrent laryngeal nerve was stimulated, when a slight adduction movement of the right cord was seen. Dr. Charles Mayo, Dr. Franklin Martin, Dr. Cabot, and Dr. Willis of America, and Dr. Tapia of Madrid, were present at the operation.

Four months after the operation the baboon was barking loudly again, and on using the laryngoscope the right vocal cord was seen to have regained its tone its inner border was straight, but it was still immobile. During this examination the anaesthesia was deep and the respiration very shallow.

Second Operation (*Left Side*), performed nine months after the first.—Recurrent laryngeal-phrenic end-to-side anastomosis.

The right vocal cord now shows a slight abduction excursion in tranquil respiration. For three months this monkey has been barking so loudly that the neighbours have complained of the barking of the "dog." After the operation which paralysed the left vocal cord the movements of adduction and abduction of the right vocal cord became quite obvious.

Six months after the second operation an examination of the movements of the diaphragm was made by Professor Elliot Smith, Dr. Beattie, and Mr. Melville, who reported as follows:

The right half of the diaphragm is contracting in the normal manner and the muscular portion appears to be completely functioning.

In the left half of the diaphragm the movement is not normal; amplitude less than that on the right side. Query: the muscular fibres are not all yet acting.

Two months before Professor Elliot Smith made this examination it was noted that this baboon suffered from stridor when excited or angry, and that the barking was less noisy, less frequent, and changed in character.

After the examination of the movements of the diaphragm an attempt was made to examine the vocal cords, but the examination was unsatisfactory and the animal died from an overdose of anaesthetic shortly afterwards. It was suspected that the stridor was due to a paradoxical movement of the vocal cords.

It may be added that the microscopical examination shows regeneration of axis cylinders in both recurrent laryngeal nerves and in both phrenic nerves below the anastomoses. All the intrinsic muscles of the larynx appear to the naked eye to be in a healthy state, though the *microscopical examination* of each intrinsic muscle is not yet complete. It is to be noted that the distal part of the descendens noni nerve was not united to the lower border of the hypoglossal; this was a mistake in the operation; the animal had a long neck, but it was believed, however, that the descendens noni was divided below the origin of the nerves to the sterno-hyoid and sterno-thyroid muscles. The nerve to the omo-hyoid muscle was divided.

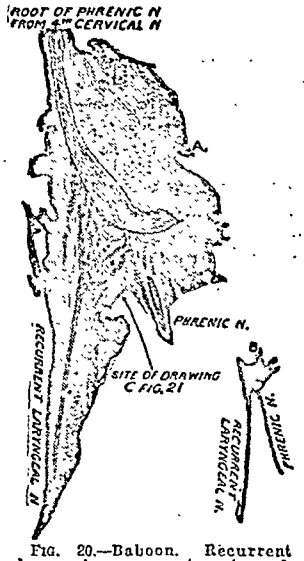

FIG. 20.—Baboon. Recurrent laryngeal nerve anastomosis, end-to-side, to the root of the phrenic nerve coming from the fourth cervical nerve (Experiment X). Death three months and twenty days after operation. B, The nerves removed after death. A, Microscopical sections. (× 10.)

The following three experiments illustrate the difficulty, even when every care is taken, of keeping monkeys alive for the long periods of time required for final results to be obtained in nerve anastomosis experiments.

EXPERIMENT IX.—*Baboon.*

Operation (Left Side).—Recurrent laryngeal-phrenic end-to-side anastomosis.

Three months later the left vocal cord showed no movement during tranquil respiration, but its border was straight and it had recovered its tone. A week after this laryngoscopic examination the monkey became ill and was destroyed by ether inhalation. Before death ensued the right recurrent laryngeal nerve was exposed and stimulated with the faradic current. The results were as follows:

Undivided recurrent laryngeal nerve:—(*a*) Weak current: both cords move equally. (*b*) Somewhat stronger current: strong adduction of opposite cord.

Divided recurrent laryngeal nerve:—(*a*) Proximal end: strong adduction of opposite cord. (*b*) Distal end—weak current: adduction of both cords. Somewhat stronger current: powerful adduction of opposite cord.

It is difficult to explain these movements of the vocal cords, but the same results were obtained in a similar case in which the recurrent laryngeal nerve on the side opposite to the one stimulated had been anastomosed to the phrenic nerve. It is worthy of note that though the left vocal cord was devoid of movement in tranquil respiration, yet when the opposite recurrent laryngeal nerve was stimulated by the faradic current its excursions were much more marked than those of the vocal cord on the normal side. It is therefore clear that a nerve current was already capable of passing through the recurrent laryngeal-phrenic anastomosis.

EXPERIMENT X.—*Baboon.*

Operation (Right Side).—Recurrent laryngeal-phrenic end-to-side anastomosis. The end-to-side anastomosis was to the root of the phrenic nerve from the fourth cervical nerve by the method of median incision. (Figs. 20 and 21.)

Three and a half months later the right cord had regained its tone—border straight. Dr. Eidinow examined the movements of the diaphragm by means of the radiographic screen; and reported that the right half of the diaphragm was contracting normally.

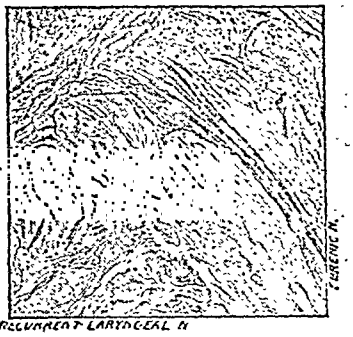

FIG. 21.—Microscopical section. (× 150.) This figure is marked C, and the site of the section is marked in Fig. 20.

The animal was taken suddenly ill and died a few days later.

EXPERIMENT XI.—*Baboon.*

Operation.—Recurrent laryngeal-phrenic end-to-end anastomosis. The end-to-end anastomosis was to the proximal part of the divided root of the phrenic nerve from the fourth cervical nerve.

One month later the animal died of tuberculosis.

[A full description of the method of taking the cinematograph pictures will be contained in the second part of the paper to be published next week.]

TRAUMA AS A CAUSE OF AURICULAR FIBRILLATION:

ITS MEDICO-LEGAL SIGNIFICANCE.

BY

JOHN HAY, D.L., M.D., F.R.C.P.,

PROFESSOR OF MEDICINE, LIVERPOOL UNIVERSITY; SENIOR PHYSICIAN, LIVERPOOL ROYAL INFIRMARY; PHYSICIAN IN CHARGE OF THE HEART DEPARTMENT, LIVERPOOL ROYAL INFIRMARY;

AND

H. WALLACE JONES, M.Sc., M.D., M.R.C.P.,

SENIOR ASSISTANT PHYSICIAN, LIVERPOOL ROYAL INFIRMARY.

(From the Heart Department of the Liverpool Royal Infirmary.)

Is trauma or physical strain to be accepted as an exciting factor in the production of auricular fibrillation?

This is a matter of considerable practical importance because of its medico-legal bearing, apart altogether from the obvious clinical interest. In the valuable and helpful book by Dr. E. M. Brockbank on *Incapacity and Disablement in its Medical Aspects* the author states quite definitely that he has "never met with a case in which auricular fibrillation could be attributed to sudden strain," and expresses the view that he would be "very unwilling to believe that strain could cause it." Since there is nothing to suggest that he has in mind the effect of strain on a healthy heart we can only conclude that he holds the view that strain will not induce fibrillation, even in a heart damaged by disease.

Our experience is contrary to that of Dr. Brockbank, and we feel that it is desirable to put on record a few cases in which the advent of fibrillation might reasonably be ascribed to trauma or physical strain.

The view is generally held that fibrillation, as met in clinical practice, is always superimposed upon a pre-existing pathological change in the heart. This probably holds good in the large majority of cases. It is open to doubt, however, whether there are not exceptions to this rule. Even granting that some myocardial change must precede fibrillation, the medico-legal question is simply whether physical effort does not prove in some instances the determining factor in its onset. And it must be remembered that once fibrillation has begun it tends to persist.

Auricular fibrillation is an added disability and is sudden in onset, though the ensuing cardiac failure resulting from the fibrillation may take time to develop and manifest itself.

That auricular fibrillation is a disability *per se* is beyond question. This is clearly shown in those patients in whom the fibrillation is paroxysmal, who know when an attack begins, and who are conscious both of the onset and the offset of the fibrillation. Such patients are clearly aware of an increased liability to shortness of breath on effort. They have no delusions in regard to the matter; previous to the onset of the disorderly rhythm they can undertake physical effort without distress, but while fibrillation is present such physical effort cannot be undertaken with comfort. When an attack is over (after a short period of subsequent exhaustion) the reserve is again unimpaired. Whatever the pathological changes in such a heart they are in existence before an attack, during an attack, and after an attack. The factor responsible for the disability is the onset and the presence of fibrillation. When that disappears the heart is back again to its old standard.

It is the ventricles which do the work of the heart. They are the pump. Their health or disease has nothing to do with the inception of fibrillation of the auricles. Their

soundness has, however, a great deal to do with their power of dealing with the abnormal conditions set up by auricular fibrillation. We refer, of course, to the increased ventricular rate and the irregular force of the systoles. The auricles pipe, and the ventricles perforce must dance. The rhythm of their dance is both rapid and irregular, and if the ventricular muscle is unsound it is a dance that sometimes leads to death.

Eyster and Swarthout have shown that fibrillation diminishes the cardiac output by 40 per cent. in dogs whose myocardium was presumably sound and vigorous, and from the clinical evidence it is clear that the inception of fibrillation means an inadequate circulation and a sudden definite increase in the load which the heart has to bear.

In fibrillation the output of blood per minute is less, but the work of the heart is increased—100 to 160 ventricular contractions instead of 60 to 70 per minute, with a corresponding diminution in the resting of the heart. In other words, there is a diminution of the pumping power in spite of a greater expenditure of energy. As the direct result of the diminished output the essential organs are poorly

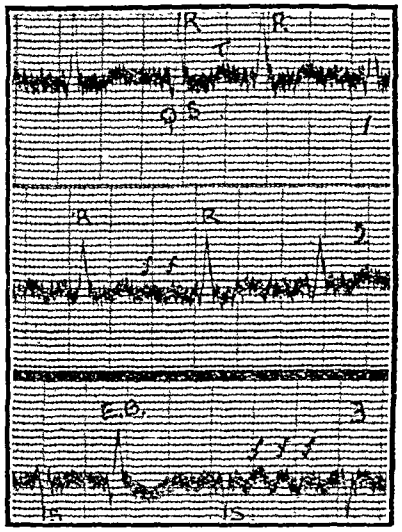

FIG. 1.—Electro-cardiogram showing fibrillation, with an ectopic beat (E.B.) in Lead 3, and relative preponderance of the left ventricle. QRS=Initial deflection of ventricular complex. f=Deflections due to fibrillation.

supplied with blood, and the individual, as an individual, becomes less efficient. Now, if it is proved that this added disability (A.F.) was brought on by the nature of a man's employment, then the employers of that man are liable. It is, therefore, important to know whether physical strain can reasonably be regarded as one exciting factor in the inception of this abnormal and disabling rhythm.

The experience of most of those who have carefully examined and cross-examined patients suffering from auricular fibrillation might be summarized as follows:

1. There is the group in which the *date of onset cannot be determined*—those patients in whom fibrillation causes little, if any, distress, and such distress not being associated in the patient's mind with any change in the heart, the myocardium being capable of tolerating the added load with equanimity. The disorderly rhythm is discovered by the doctor in the course of his physical examination. In this group one must place also those who present themselves with symptoms of cardiac failure, who believe that the heart is at fault, but who were unaware of the onset of the irregularity which is present.

2. There is the group in which the moment of the *onset of fibrillation can be clearly defined*, either because the patient recognized the sudden change in cardiac rhythm, or because the medical attendant (as the result of his own observations) is able to determine the date of the change in rhythm to within a day, or even within a few hours, of its onset—the predisposing influences in such a group being toxic influences, such as influenza, pneumonia, hyperthyroidism, or digitalis. Sudden emotional disturbance may have been the responsible factor. In this group one might also include those in whom there was no apparent exciting cause. The moment of onset was recognized, the predisposing condition being that of old-standing heart disease.

3. There is the third and smallest group in which fibrillation followed immediately upon some definite effort or physical strain. The onset, in point of time, was clearly defined and was closely associated with the effort or strain or shock—so much so that it would be unreasonable not to admit the relationship.

It is this third group which interests us.

Dr. J. G. Emanuel, in the Ingleby Lectures, 1925, gives the conditions associated with the onset of auricular fibrillation in 52 patients in whom the onset of the fibrillation was accurately noted. Among the conditions noted were:

Running for a tram	2 cases
Walking uphill	4 „
Climbing steps or stairs	3 „
Coughing violently	5 „
Laughing heartily	2 „
Unscrewing steam pipe	1 case
Considered due to an electric shock	1 „

Dr. Emanuel does not go so far as to say that the physical effort in the above patients was the exciting cause,

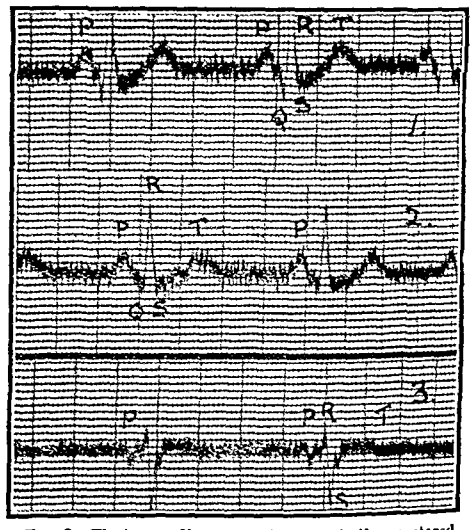

FIG. 2.—Electro-cardiogram. Normal rhythm restored. P=Deflection caused by systole of the auricles. P is absent in fibrillation.

and he accepts the view that "for fibrillation to occur the heart must be affected by rheumatism, syphilis, arteriosclerosis, Graves's disease, or some toxaemia." It is certainly true that myocardial damage or some toxaemia is generally present as a predisposing factor, but we do not believe that either is essential. In any case, the *point* at issue is rather whether physical strain or shock can precipitate the onset of fibrillation, either in a damaged heart or even in a heart which is apparently normal.

It is well known that auricular fibrillation, essentially a functional condition, is easily induced in the healthy heart of an animal, and it has been demonstrated that in animals both interrupted galvanic current and faradic shocks cause fibrillation.[1]

It is significant that in such experiments the fibrillation so produced does not cease when the stimulus which produced it is no longer active, but continues for an appreciable time, "*after fibrillation.*"[2]

In 1913 Gossage and Hicks published one or two cases in which fibrillation occurred spontaneously in young patients with apparently healthy hearts.[3]

The cases which we propose to relate appear to justify the view (1) that the functional disability of fibrillation may be induced by sudden strenuous physical effort, or by a severe electric shock; (2) that fibrillation can occur in a heart which is sound as judged by ordinary clinical methods. And we hold it is a reasonable assumption that physical strain and effort does *still more* readily induce fibrillation in hearts already predisposed to its onset by myocardial damage or some toxaemia.

CASE I.—*Auricular Fibrillation following Exposure to Electric Current.*

Our first case is that of a healthy man exposed to a powerful electric current, with the result that auricular fibrillation replaced the normal rhythm of the heart. His age was 35. He had always been in excellent health, and there was no history of any rheumatic or syphilitic infection. On April 13th, 1926, he was sitting on an electric crane and accidentally placed his forehead against the "live terminals" of the crane, receiving 250 volts of "direct current." He experienced an intense burning sensation over the right eye and through the whole of the right side of the body, and was unable to release himself from the terminals for about two minutes—until, in fact, it was possible to switch off the current.

He was assisted to the ground in a very prostrate and collapsed condition and the burns of the face and hands were dressed. The nurse who attended to him states that at that time the pulse was markedly irregular and rapid. He slept that night at the St. Helens Cottage Hospital and returned home by tram-car the next day. Later in the day he went for a walk but returned in fifteen minutes "quite exhausted," and he himself noticed that his pulse was irregular.

Five weeks later he came to the heart clinic of the Royal Infirmary for examination and was admitted for treatment. He was a strong, plump, healthy looking man. Clinical examination failed to reveal signs of disease in any organ. The heart was slightly enlarged (apex beat 4¾ in. from mid-sternal line) and the cardiac action was completely irregular. The Wassermann reaction was negative. (Fig. 1.)

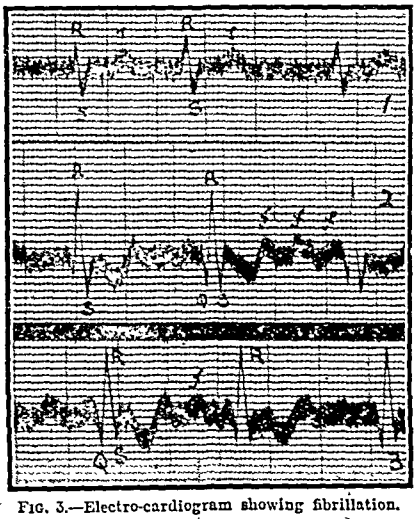

FIG. 3.—Electro-cardiogram showing fibrillation.

Tincture of digitalis was prescribed in 3p doses daily. At the end of eight days there was no change in the heart rate, and on June 4th treatment by quinidine sulphate in doses of 0.2 gram was begun. He received one dose every seventy-five minutes, and normal rhythm was restored after eighteen doses—3.6 grams in all. The heart rate became 70 per minute and regular. (Fig. 2.)

Fibrillation, once induced, tends to recur, and we were not surprised when on June 10th he reverted to fibrillation. Normal rhythm returned after 1.6 grams of quinidine, but in twenty-four hours (on June 12th) the auricles again fibrillated. After another 2 grams of quinidine the rhythm became normal and has remained normal up to the present (March, 1927).

He continued to take quinidine in capsules of 0.2 gram four times daily. This amount of quinidine has been reduced gradually, and he now takes one capsule every third day. He has had no return of the fibrillation, feels quite well, and has resumed his occupation of electrical mechanic, entailing moderately heavy work.

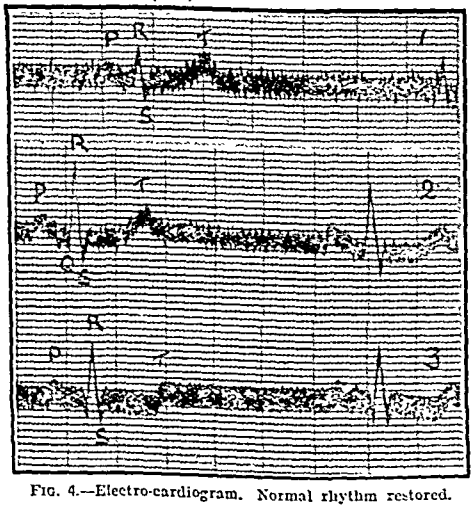

FIG. 4.—Electro-cardiogram. Normal rhythm restored.

We are much indebted to Dr. John Roberts of the Glass Works, St. Helens, for the details of the accident and for the opportunity of treating this patient.

The next case is an example of auricular fibrillation induced by a combination of sudden physical effort and excitement.

CASE II.—*Auricular Fibrillation following Sudden Physical Effort and Alarm.*

The patient was a man, aged 32, in good health. One evening in July, 1912, he was walking home after a good supper of pastry and buttermilk when he was attacked by a dog. He was extremely frightened and with great difficulty struggled over a high wall. He was at once conscious of a peculiar sensation over the heart, and from that time suffered from shortness of breath and pain about the left shoulder-blade on any exertion.

On examination the heart was slightly enlarged, extending 4½ in. to the left of the mid-sternal line. There were no bruits. The heart rate was 100 and disorderly. Blood pressure 130 mm. Hg systolic for the larger beats.

Two months later, after treatment by rest and digitalis, the action of the heart, though still disorderly, was about 80, and the cardiac dullness 3¾ in. from the mid-line of the sternum, indicating that when first examined the dilatation of the heart was probably secondary to the fibrillation.

In April, 1926, fourteen years later, fibrillation was still present. The heart dullness extended 4½ in. from the mid-sternal line and a soft systolic murmur was occasionally heard over the mitral area. Digitalis is still required to steady the heart, but he is able to carry on his business so long as he is reasonably careful.

CASE III.—*Auricular Fibrillation during a Struggle.*

This patient was a man in whom fibrillation came on while he struggled with a horse. It bolted and he seized it by the bridle and had to run with it for over 100 yards, dragging at its head. He was a healthy man with a sound heart previous to this adventure. There was no history of any rheumatic infection. The fibrillation has persisted.

In neither Case II nor Case III was quinidine sulphate administered, as both developed their fibrillation more than ten years ago, before this was a recognized mode of treatment.

CASE IV.—*Auricular Fibrillation Precipitated by Sudden Effort.*

A man, aged 50, in 1922 ran hard to catch a train, and noticed at once that the action of his heart had become peculiar. He complained of a constant sensation of tightness around the chest and palpitation on the slightest exertion. On examination the ventricular rate was 120 and disorderly in rhythm. There was no evidence of valvular defect, but the heart was a little enlarged, and the deep cardiac dullness extended 4½ in. from the mid-sternal line. (Fig. 3.) The day before the onset of the fibrillation he had been examined for life insurance and the heart had been passed as normal in every respect. The fibrillation yielded to 0.4 gram of quinidine sulphate. (Fig. 4.)

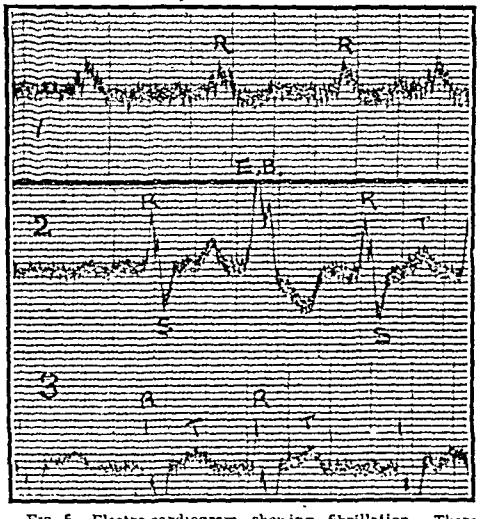

FIG. 5.—Electro-cardiogram showing fibrillation. There is, in addition, evidence of some degree of block in the right branch of the A-V bundle, and of an ectopic beat (E.B.).

In the summer of 1924 he had another attack, which was again terminated by quinidine sulphate.

His last attack, in November, 1926, was again caused by running smartly for a train. Within ten hours of the onset quinidine was given by Dr. E. Noble Chamberlain, and after a total dosage of 0.8 gram normal action of the heart was restored.

This patient is somewhat predisposed to fibrillation, for he gave an account of an illness in 1918 for which he was in hospital a

fortnight, and which, from his description, was similar to that in 1922. The significant fact, however, is that the attacks in 1922 and 1926 were undoubtedly due to severe physical effort.

CASE V.—*Auricular Fibrillation Started by Lifting a Heavy Weight.*

A man, aged 57, was apparently efficient until the onset of his present disability; he experienced no discomfort on exercise and was not conscious in any degree of the action of his heart. Twenty years ago he was in hospital suffering from rheumatic fever.

On January 30th, 1925, he was *lifting a heavy "hip" on to a roof when he felt something give* in his chest. His heart seemed to stop beating and then to race, there was acute pain all over the chest and he became very short of breath. He sat down for half an hour, during which time his heart continued to race. He was conscious of respiratory distress. The following day the pain was still present and the dyspnoea marked. He was seen by his doctor and later was admitted to one of the Liverpool infirmaries. While there a diagnosis was made of "strained heart."

He was a fairly well nourished man; he presented no cyanosis nor oedema. The conjunctivae were rather watery. There was marked dyspnoea on any exertion, even on walking slowly. This was accompanied by pain in the mid-line behind the sternum; the pain did not radiate in any direction. Pulse 160, very irregular; blood pressure for the larger beats 150 systolic, 60 diastolic. Cardiac thrust in the fifth and sixth spaces. Deep cardiac dullness 5½ in. to the left. There was a loud blowing systolic murmur over the apex beat—murmur conducted outwards and to some extent inwards; a short rough systolic over the aortic area, and a faint diastolic extending down to the left of the sternum audible during the long pauses.

The liver was enlarged and hard, 2 in. below the costal margin (he admitted taking four pints of beer daily). The urine contained a fair amount of albumin. The electro-cardiogram showed a rapid heart with a right bundle lesion (Fig. 5) and occasional ectopic beats originating in the right ventricle.

He responded well to digitalis, and his cardiac reserve increased, but he has never been able to work since the onset of the trouble.

It is reasonable to infer that fibrillation was the result of the sudden strain.

In Case v there was pre-existing disease both of the valves and of the myocardium, and the patient was more likely to suffer from physical strain than a normal healthy man. He broke down in consequence of the strain of his employment, and his employers were consequently liable. This has been recognized by them, and he is drawing full compensation for total disability. In reference to one case the law lords laid down that:

"If a man, in lifting a weight or trying to move something not easily moved, were to strain a muscle, or rick his back, or rupture himself, the mishap, in ordinary parlance, would be described as an accident."

"Were to strain a muscle." This man strained the most important muscle in his body—his heart—and its auricles fibrillated.

Summary.

Five cases are recorded in which fibrillation resulted from trauma; in one case the exciting factor was a powerful electric shock; in the remaining four the exciting factor was sudden physical exertion putting an unexpected and undue strain on the heart. In four of these men there was no evidence that the heart was diseased or abnormal, and up to the onset of fibrillation they were living active normal lives.

We hold that the evidence justifies the view that sudden strain may, and frequently does, initiate auricular fibrillation and induce cardiac failure in men and women with diseased hearts. We would go further and say that fibrillation may result from physical strain in hearts that are apparently normal, so far as can be determined by *ordinary clinical methods.*

The medico-legal significance of this is of considerable practical importance, and it was for this reason that we have put these cases on record.

ULTRA-VIOLET RAYS: THEIR PLACE IN MEDICINE.*

BY

F. HERNAMAN-JOHNSON, M.D.ABERD., D.M.R.E.CAMB.,

RADIOLOGIST TO THE FRENCH HOSPITAL, LONDON; PHYSICIAN IN CHARGE, X-RAY AND ACTINO-THERAPEUTIC DEPARTMENT, CROYDON GENERAL HOSPITAL.

IN certain quarters a prejudice against light treatment exists because of the multiplicity of disorders for which it is recommended. As definite effects upon the skin can be demonstrated, claims for the value of ultra-violet rays in dermatological cases do not, as a rule, meet with much opposition; but when the same agent is said to be useful in all forms of tuberculosis, in rickets, in various diseases of the blood and lymph glands, rheumatism, neuritis, herpes, organic diseases of the nervous system, syphilis, and even cancer, the orthodox may be pardoned for an inclination to class such a remedy with those advertised in the pages of popular magazines. Yet all the maladies enumerated have really been cured or improved by ultra-violet rays, used either alone or in combination with other forms of radiant energy. Apart from mechanical interference with the function of organs, the greater part of organic disease is directly due to the action of circulating poisons, and of these poisons the majority are of microbial origin.

In disturbances of health caused by microbial invasion the symptoms are not due to the microbes as such (embolism apart), but to the toxins they generate. Nevertheless, provision is made in the body, by phagocytic attack, to deal with the actual germs, as well as with their poisonous products.

Medical treatment must aid and stimulate natural processes. For the most part direct aid is impossible at present; diphtheria antitoxin is about the only example. Vaccines, and even so-called specific drugs, such as neo-salvarsan and quinine, are valuable only so long as the host-tissues retain a power of response. The modes of reaction of the body to external stimuli are comparatively few, although the stimuli themselves may be almost infinitely varied. A similar result may be brought about by diverse causes, or apparently diverse results by a single cause. If we can discern an agent capable of activating, at least in some degree, all the defence mechanisms of the body, then the list of diseases in which it is of value will be large.

An approach to such an agent we possess in ultra-violet rays. All radiation is due to the vibration of electrons, and travels in the form of waves through the ether. The sole difference between one form of radiation and another lies in their respective frequencies. In the case of visible light the eye and brain interpret the frequency in terms of colour; in the case of invisible light —ultra-violet rays and x rays—the skin shows itself capable of distinguishing between different frequencies or wave-lengths by its reaction. For example, an erythema follows an ultra-violet exposure in eight to ten hours, but after x-ray exposure requires as many days to develop. And, in the former case, hair is stimulated, whereas in the latter epilation occurs, and regeneration is not well established for two or three months.

There are three well known types of lamp for the production of ultra-violet rays—the carbon arc, the tungsten arc, and the mercury vapour arc. The former is the most suitable for general treatment; the two latter are capable of producing erythema in a few minutes, and are best suited for local treatment. The production of erythema would appear to be for the most part essential to the successful local treatment of skin disease. Acne, dry eczema, alopecia, impetigo, pruritus, boils, scleroderma, and extensive varicose ulcers are some of the conditions which yield to local applications. A series of erythema doses over the painful area in cases of neuritis, sciatica, and lumbago will often effect a cure; and, applied over the lower abdomen, may relieve the pain of cystitis. These results may be "explained" by saying that the erythema induces a local phagocytosis, and that, in the case of deep-lying trouble, cure is brought about by counter-irritation.

* Abstract of an address to the Croydon Division of the British Medical Association.

The effects of general radiation are clinically no less definite, but many medical men refuse to credit this. Steenbock and Black, of the University of Wisconsin, have shown that ultra-violet rays can reactivate cod-liver oil the antirachitic power of which has been destroyed by heat; and can also confer this power upon other fats, including that present in the human skin. This "explains" their action in rickets in terms of cod-liver oil. Again, Leonard Hill and his co-workers have proved that an erythema dose over about one-quarter of the body surface raises the bactericidal power of the blood. Here is a possible explanation, in bacteriological terms—which, by virtue of thirty years' use, have become familiar and respectable—of the action of ultra-violet rays in tuberculosis. But when it is stated, for example, that great benefit may result from their use in disseminated sclerosis, in pernicious anaemia, and in Hodgkin's disease, there is no obvious link with familiar facts.* Yet it is generally believed that these disorders are the result of toxins, and that these toxins are probably of microbial origin. The bodily resistance to known toxins is raised by ultra-violet rays, and this stimulation is effective against such widely different organisms as the tubercle bacillus and the cocci of suppuration. Surely, then, it is not very difficult to admit that it may be effective against other, and at present unknown, organisms.

It is often said that light treatment is useless, and even dangerous, in phthisis, but by cautious dosage—erythema should be avoided—and a careful selection of cases, much good may be done. The patients must not be very ill, nor must they be of the well known type which offers little resistance to the spread of the disease. The kind of patient who would in any case struggle on for some years, doing a certain amount of work, is the one who will derive definite benefit. His working life will be prolonged, and his outlook on life altered for the better.

If we bear in mind steadily that for the most part light acts as a stimulus to natural power of defence, we shall understand its limitations. The moribund patient cannot respond, and the patient with high temperature is in no state to answer further calls. Ill health of any kind due to a concealed septic focus cannot be permanently benefited. "Rheumatic" or "neuritic" pains caused by an abscess at the apex of a tooth are examples in point. When, however, we suspect a toxin, but cannot locate it, the use of light is justified in so far as it places the patient in the best possible condition to resist the hypothetical poison.

Finally, it should be noted that ultra-violet rays form but a small part of the total of wave-lengths in nature; and while their value is great, even if used alone, it is vastly enhanced by a combination with other radiations, notably x rays. Their addition is an essential factor in the cure of some skin troubles; and, on the other hand, x rays may be employed more freely in deep-seated cancer if ultra-violet rays are used to prevent injurious effects on the blood.

The actual carrying out of light treatment may well be delegated to competent lay operators, acting upon definite prescriptions. But the indiscriminate use—or, rather, abuse—by unqualified persons of ultra-violet rays as a cure-all is likely to bring discredit upon the treatment.

* Since the delivery of this address good results have been obtained in the treatment of the inco-ordination and depression which follow "sleepy sickness."

SPORADIC BACILLARY DYSENTERY IN ENGLAND.

BY

G. W. N. JOSEPH, M.D., D.P.H.,
MEDICAL OFFICER OF HEALTH FOR WARRINGTON;
AND
J. S. MANSON, M.D., D.P.H.,
MEDICAL OFFICER OF HEALTH FOR THE RURAL DISTRICT OF RUNCORN.

THE following brief account of two recent outbreaks of dysentery or pseudo-dysentery, chiefly affecting children, would seem worthy of record, especially in view of the pathological and bacteriological findings. The sudden and limited outbreak, confined in each case to one household, seemed to point to some kind of food poisoning, and it was with the view of ascertaining the character of the toxic agent that a complete pathological and bacteriological examination was made in the first outbreak described.

The first outbreak involved four children from one household in Warrington. The first child attacked, S. D., aged 1 year and 9 months, became ill on February 27th, 1926, with sickness and drowsiness; then severe diarrhoea set in. Three days afterwards (on March 2nd) A. D., aged 6 years, and G. D., aged 4 years, were taken ill with sickness and diarrhoea. All three were noted to be drowsy at the commencement of the illness. Dr. David Meikle, their medical attendant, stated: "All had symptoms of acute gastro-enteritis, vomiting, diarrhoea, green stools loaded with mucus, no blood or rise of temperature, rapid but regular pulse. The two elder children were semi-conscious, but the youngest was quite conscious. The eldest had had an epileptiform seizure in the night." R. B., aged 2 years and 9 months, was taken ill on March 4th with vomiting and diarrhoea. Drowsiness was not noted in this case.

All the children were removed to Whitecross Hospital, Warrington, on March 4th. S. D. died on March 8th, and R. B. on March 9th, and *post-mortem* examinations were ordered by the coroner. A. D. and G. D. survived.

Post-mortem Examinations.

S. D.—The body was that of a well nourished male child. *Post-mortem* lividity was well marked over the back and buttocks. Rigor mortis was present. The heart and lungs were normal; the left ventricle contained a large amount of dark fluid blood, and there was a large dark clot in the right auricle. The liver, spleen, kidneys, and pancreas were normal. The stomach, which was practically empty, was removed between ligatures for further examination. About the middle of the small intestine signs of congestion appeared, and continued to its junction with the large intestine, which was very congested, showing haemorrhagic patches of inflammation studding the large intestine almost throughout its whole length.

R. B.—The body was that of a well nourished male child. The body was warm, and rigor mortis had not yet set in. *Post-mortem* lividity was present in slight degree. The heart and lungs were normal. There was a small amount of dark fluid blood in the left ventricle, and a slight amount of *post-mortem* clot in the right ventricle and auricle. The stomach was removed between ligatures unopened for further investigation. The large intestine was also removed between ligatures. The lymph glands in the mesentery of the large intestine presented a remarkable appearance. There was a continuous row of enlarged lymph glands close to the intestine throughout the whole of its length. The other glands in the mesentery were also enlarged. The small intestines contained dark coloured faecal matter, and the ileum was much congested, and contained dark fluid blood. The liver, spleen, and kidneys seemed normal. The brain vessels were congested to a moderate degree with dark fluid blood, but were otherwise normal.

As food poisoning was suspected, the stomachs, intestines, and pieces of the kidneys, liver, and spleen were sent to the pathological laboratory of the Ministry of Health, packed in 30 per cent. glycerin. The pathologist's report, dated March 17th, 1926, was received from Dr. A. W. MacFadden. It was as follows:

"None of the specific food poisoning organisms or dysentery bacilli could be found in the tissues from the two cases. The circumstances point, I think, to an acute infection of the gastro-intestinal tract, and I should suspect an infection of *B. aertrycke*. It would be useful to test the serums of the surviving children against this organism and against the Morgan's bacillus, which I obtained from small intestine and liver of S. D."

Samples of blood from the surviving children were requested in order to test the serums for agglutinating properties. A blood sample from A. D. was sent, and the report was as follows:

"The blood serum from A. D. shows no trace of agglutinin for the *aertrycke* group of bacteria—that is, there is no evidence that the outbreak was one of 'food poisoning.' But the blood serum agglutinates the *B. dysenteriae* 'Y,' which indicates that the condition was almost certainly bacillary dysentery."

A good sample of blood could not be obtained from the other surviving child, G. D., but blister fluid resulting from emplastrum cantharidis was sent. This blister fluid gave no agglutination with *B. dysenteriae*. It may be that the absorption of cantharidin in the blister fluid affected any agglutinating properties that it possessed.

A careful investigation of the food eaten by the affected children was made by Chief Inspector Flood. Their meals consisted of toast and tea for breakfast, chip potatoes and cakes at midday, and eggs boiled and made into sandwiches for tea. The mother stated that the boy A. D. told her that the children were playing in the ash-bins on the morning of February 27th, and that S. D. was seen eating

orange peel picked from the bins. No tinned salmon, meat, or milk, or prepared foods of any kind had recently been used in the house. No other persons in the household or other children in the neighbourhood had been ill in a similar manner.

The other outbreak occurred at Antrobus, Cheshire, and was reported to one of us (J. S. M.) by Dr. Love of Great Budworth.

A boy, aged 4 years, was taken ill on December 1st, 1925, with vomiting and diarrhoea, temperature 102°. There was a little blood in one of the motions. Two days later the temperature became normal, and the child seemed better. On Monday, December 6th, diarrhoea recurred, and the temperature rose to 100°, with pain in the left side of the abdomen. At 2 a.m. on December 7th he had acute pain in the left side of the abdomen, with great distension. He was sent to a Manchester nursing home for operation, but died before any operation was performed. A sister, aged 2½ years, was taken ill on December 4th with diarrhoea and vomiting; blood and mucus were present in the stools. Diarrhoea continued until December 9th. The child recovered. A maid and visitor in the house also had diarrhoea for a couple of days. Mrs. C., aged 35, was taken ill on December 13th with frequent diarrhoea—blood, mucus, and shreds in the stools. A specimen of this was sent to the Runcorn Research Laboratory in a sterile bottle, and Dr. H. A. Mitchell reported as follows:

"Cultivations made from this specimen have yielded cultures of (1) *B. coli communis*, (2) a Gram-negative non-motile bacillus producing a turbidity in broth. It causes acid production in glucose, mannite, and maltose, but has no effect on saccharose, lactose, dulcite, and raffinose, nor on litmus milk or gelatin. It failed to form indol, and gave only slight agglutination with specific Flexner 'Y' serum. Classification, *Bacillus paradysenteriae* closely resembling the Flexner 'Y' type as described by Park and Williams."

A culture of this organism was sent to the Ministry of Health laboratory, and the report was as follows:

"The culture gives the fermentation reactions of the Flexner group of the *B. dysenteriae*, but fails to form indol, and gives only insignificant traces of agglutination or none with the specific serums of all the types of the Flexner group. It is not one of the standard dysentery bacilli, but may possibly be pathogenic."

A sample of blood was taken from Mrs. C. to test its agglutinating properties. This sample proved insufficient, and the patient refused to allow another sample to be taken.

The cases in this household were at first thought to be due to food poisoning, but nothing could be discovered likely to produce the condition. Milk and water were examined, and the well, formerly of good repute, which supplied the household was found to contain *Bacillus coli* in 1 c.cm. Other users of this water were not affected. All were warned to boil the water after the contamination was revealed. These cases, together with an account of an outbreak published by one of us (J. S. M.) in 1921 (*Lancet*, April 16th, p. 802), show that small localized and virulent outbreaks of colitis occur in this country, especially affecting children, and evidently have some etiological relationship to a bacillus of the dysenteric group of the Flexner "Y" type.

MEDICAL, SURGICAL, OBSTETRICAL.

THE OPERATION OF TONSILLECTOMY.

I was interested to read in your issue of January 8th (p. 56) an account by Dr. Lodge of an ambidextrous method of performing tonsillectomy, though a little befogged by the various anatomical movements described. Many years ago it occurred to me that ambidexterity in tonsillectomy would be a great advantage in securing without change of position the second tonsil, which so quickly becomes obscured by blood, and consequently I set about practising it. The steps of the operation are as follows.

Doyen's gag is introduced slightly to the left of the middle line and ethyl chloride administered. The operator stands on the patient's right, the nurse on the left, and the anaesthetist in the usual position at the head of the table. The nurse holds two adenoid curettes (Sir StClair Thomson's for preference), one in each hand, with the blades uppermost. I invariably use artificial light as it makes one independent of dull days and inadequately lighted rooms.

If the operation is performed in an institution the head of the table is slightly raised, the sliding electric lamp pulled down by the anaesthetist, and the light reflected into the mouth from the ordinary forehead mirror worn by the operator. I have got into the habit of removing the left tonsil first, therefore I take the guillotine (Jenkins's guillotine for choice, the blade of which can be blunted on sandstone) in the left hand, depress the tongue with the index finger of the disengaged hand, and completely expose the tonsil to be enucleated. The ring of the guillotine is then passed over the lower pole, the handle of the instrument brought right across to the opposite side and depressed, while the point is raised and pushed well behind the tonsil, which with the soft palate in front of it is pushed well forwards. The index finger is then released from the tongue and used to push the tonsil (which can be distinctly felt under the soft palate) through the ring of the instrument until the circumference of the latter can be felt all round; the blade is then driven home and with a slightly wriggling movement the tonsil is brought out entire.

The guillotine is next taken in the other hand and the procedure repeated on the other tonsil. The nurse then relieves the operator of the guillotine and places a curette in his hand (one usually suffices); it is passed into the mouth blade downwards until it reaches the pharynx; it is then rotated through 180 degrees and passed up behind the soft palate until it impinges on the posterior end of the septum; it is then pushed backwards and upwards, and finally levered downwards in one sweep, using the incisor teeth as a fulcrum, and the adenoid growth brought out in the cage.

In this way I have enucleated many thousands of tonsils, and during the past three years have been most ably assisted by my colleague, Dr. Macleod, senior medical officer, Hull Dispensary, who has anaesthetized some 3,000 patients for me without a hitch.

I wish it to be understood that I am not claiming anything new or original—the method of enucleating the tonsils described above will be recognized as that introduced by Whillis and Pybus some years ago, and is, I believe, in general use—I am simply giving my experience as to how, with a combination of artificial light, team work, and ambidexterity, the operation which has taken so long to describe can be performed in a few seconds.

ALFRED J. S. ROE,
Aural Surgeon, Hull Dispensary.

PULMONARY EMBOLISM FOLLOWING CHILDBIRTH.

THE following case, which occurred in 1925, may be of interest in connexion with the two cases reported in the BRITISH MEDICAL JOURNAL of November 6th, 1926 (p. 835).

A healthy woman, aged 27, gave birth to her third child after a perfectly normal labour and without any intervention. I was not present at the birth, but was sent for two hours later by the nurse. I found the patient complaining of faintness, with a livid face and anxious expression, laboured breathing of 40, and a pulse rate of 160. The placenta had been delivered normally soon after birth and there had been no abnormal loss of blood. The uterus was fully contracted. Examination of the heart revealed no bruits, but the sounds were greatly accentuated, the second in the pulmonary area being exceptionally loud and sharp. During the examination the heart rate increased rapidly to 200.

Various stimulants were given, such as intramuscular injections of camphor, ether, strychnine, and digitaline, but without effect.

The patient vomited once and then lapsed into unconsciousness, and died in less than fifteen minutes after my arrival.

No *post-mortem* examination was performed, but the only possible diagnosis seemed to be that of pulmonary embolism.

G. W. V. PARRY, M.R.C.S., L.R.C.P.
St. David's, S. Wales.

OCULAR SYMPTOMS DURING CATAMENIA.

IN the issue of the BRITISH MEDICAL JOURNAL dated May 8th and 15th, 1926 (*Epitome*, para. 503), a case of retinal haemorrhage synchronous with onset of menstrual period is described. The patient subsequently developed scleritis and she proved to be tuberculous. In view of this it may be of interest to record the following case.

A married woman, aged 29, reported that her left eye regularly became sore two days before menstruation and cleared up two days after menstruation ceased. She was found to have mild episcleritis. A month's local treatment with 1 per cent. yellow mercuric oxide ointment and massage was not successful in preventing a recurrence of the phenomenon. On obtaining a history of acute rheumatism, regular doses of sodium salicylate (15 grains thrice daily) were administered by the mouth, with the result that the patient has not had a relapse for six months, although treatment was only continued for two months.

A. WOLSELEY D'OMBRAIN, M.B., CH.M.SYD.,
Honorary Ophthalmic Surgeon to the West Maitland, Kurri Kurri, and Cessnock District Hospitals, New South Wales.

Reports of Societies.

USES AND LIMITATIONS OF ULTRA-VIOLET RADIATION THERAPY.

AT a joint meeting of the Sections of Medicine, Dermatology, and Children's Diseases of the Royal Society of Medicine on March 22nd, a discussion was held on the uses and limitations of ultra-violet radiation therapy, Dr. HUGH THURSFIELD in the chair.

Dr. S. ERNEST DORE said that the history of light therapy in its local application in cutaneous diseases went back to 1893-94, to the introduction of red-light treatment of smallpox and concentrated sun and arc-light treatment of lupus vulgaris by Finsen. Phototherapy by means of concentrated actinic rays was introduced into this country about 1900, when Finsen's lamp was employed at the London Hospital. That lamp was still in use, but in other quarters it had been largely superseded by the smaller Finsen-Reyn lamp. Light treatment might be said to have reached its level in this country twenty years ago, when it was generally recognized as a valuable therapeutic measure, chiefly in diseases of the skin, but for some reason, possibly the superior claims of *x* rays, it did not come into use for general purposes until much later. In 1916 the Simpson lamp was introduced, for which exaggerated results were claimed at the time. It was even stated that with this lamp asthma and other conditions were benefited, not only by exposure to the light, but by inhalation of the fumes from the burning of the wolfram electrode. In 1918-19 the combined use of local and general light treatment in lupus began, mercury vapour and tungsten lamps being largely employed. Light treatment in its general application in constitutional diseases might be said to have started in 1902-3 when Bernhard and Rollier employed heliotherapy in surgical tuberculosis, followed by Gauvain in 1908, using natural and artificial light. In 1919 Huldschinsky demonstrated the value of ultra-violet radiations in human rickets —work which was confirmed by English and American observers. No discussion of light treatment would be complete without reference to its possible harmful effects. The bogy of carcinoma as a sequel to ultra-violet treatment had been laid by Dr. Reyn and Dr. Sequeira, both of whom stated that they had never seen such a case. Certain mechanical dangers might be mentioned, such as the breaking of quartz burners, fire from spluttering electrodes, and electric shock. Too frequent or lengthy sessions might produce debility and depression, and there was always the possibility of aggravating a latent tuberculosis. Ultra-violet radiation treatment had recently received a great impetus. It was being used in many new directions. He knew of one medical practitioner who regularly employed it as a preventive measure for persons who were quite well. Its increasing use in municipal clinics might be excellent, but he thought that something ought to be done to check exaggerated statements which gave rise to false expectations.

Dr. H. M. ODDY spoke of the applications of light in children's diseases. Children usually reacted much more quickly than adults, therefore the dose had to be reduced appropriately. It had been suggested that for children half the normal adult dose should be given, and for infants half the child dose. It was much more difficult to produce an erythema in a young child than in an adult, and this meant that the *minimum* erythema dose could not be used in the treatment of children. The symptoms of over-dosage were increased irritability and restlessness, with possibly disturbed sleep, persistent loss of weight or failure to gain weight under treatment, and perhaps digestive disturbance and loss of appetite. He thought that better results were obtained on the whole with mercury vapour than with the carbon arc, except perhaps in surgical tuberculosis. The length of treatment must vary with the disease, but from twelve to twenty treatments at the rate of two or three a week should be followed by a month or two of rest. In small infants pigmentation did not occur as a rule, but in spite of its absence the clinical results were excellent. Metabolism was much improved by light baths, and although Dr. Leonard Hill had shown that this was mainly due to the effect of cold air on the skin rather than to ultra-violet radiation, since exposure of the skin was necessary for the treatment the two could hardly be dissociated. The radiation was a valuable adjunct in the treatment of rickets. It was indicated also in surgical tuberculosis unless there was active disease in the lungs. If the disease in the lungs was quiescent, treatment might be given with great care, but it must be avoided in all cases where there was pyrexia. Bone and joint cases did better under light treatment than peritonitis or gland cases. Light was useful for the nursing mother whose milk showed signs of failing, and for the infant suffering from malnutrition. Among older children, the pale, thin child, *with hypotonic muscles, though with no evidence of disease*, often showed good results under light, but there were more failures than one would expect. For debility following severe illness or operation there was no tonic so good as the light bath. In some cases of asthma light baths did a certain amount of good. Of the treatment in blood conditions he had had little experience, but in theory he thought it contraindicated in leukaemia.

Dr. ALBERT EIDINOW said that experiment had shown that there was no direct bactericidal action of light in the living tissue; experiments as to whether light, acting on the skin or tissue, produced some bactericidal substance which became absorbed and carried through the circulation were not yet complete, but it could be said that an erythema dose of light produced a leucocytosis beneath the skin, and this fact gave some clue to the biological action. There was permeation of the plasma through the capillary wall, and wandering leucocytes were found in the oedematous tissue. It had been shown that the skin rapidly became immune to the action of ultra-violet radiation. The surface of the skin exposed had an important bearing on the clinical result; experiment had shown that there was a definite optimum area of skin to expose—namely, one-sixth of the surface area of the animal or patient under investigation. Bearing this in mind, a patient could be kept in a state sensitive to light for a long time with short exposures. It was quite possible that many of the bad and indifferent results with light were due to the fact that the skin had become immune through repeated doses. The question of dosage, to his mind, depended much more on the area of skin exposed than on the actual quantity of light employed.

Sir HENRY GAUVAIN remarked that very little work had been done on pure or unmixed ultra-violet radiation, and a point to bear in mind in considering all the results was the possible effect of other rays which were ordinarily mixed with those in the ultra-violet. In natural sun treatment, which was still the best form of radiant treatment, at all events in surgical tuberculosis, the proportions of infra-red rays, visible rays, and ultra-violet rays were said to be respectively 80, 19, and 1 per cent. A larger proportion of ultra-violet radiation was obtained with the carbon arc, but the carbon arc light baths were not so good as the natural sun baths, and in the case of mercury vapour, in which the proportion of ultra-violet was greater still, the value was even less. In other words, in the treatment of surgical tuberculosis the sun came first, the carbon arc second, and the mercury vapour lamp a long way behind. Thus there must be a great deal of value in the radiations other than ultra-violet, or if these other radiations had no positive action themselves they might, by some dilution and modification, intensify the value of the ultra-violet. The value of light largely depended on the power of response of the individual treated, and one reaction which personally he considered of very great importance was pigmentation of the skin. Pigmenters, in the majority of cases, did very much better than non-pigmenters. In surgical tuberculosis the healing lesions were healed more rapidly under light treatment, but in the case of progressive lesions there was no such effect.

Dr. J. H. SEQUEIRA agreed with Sir Henry Gauvain's remarks about the utility of the mixed rays. In all his clinical work at present he was using mixed rays, and he entirely agreed also with the order of importance of the various sources which Sir Henry Gauvain had given: the sun first, the carbon arc, perhaps reinforced by tungsten, second,

and the mercury vapour, with a more limited field, third. General treatment, without any local measures whatever, had been declared effective in the healing of lupus vulgaris, both of the skin and the mucous membrane, and this had been confirmed in his own clinic, but in no case was it wise, even in the treatment of a disease like lupus, which reacted both locally and generally to light, to rely entirely upon the general irradiation of the body. Some work had been done on the action of light on basal metabolism. Dr. Argyll Campbell, working in Dr. Sequeira's clinic, had found that no change in the basal metabolism was produced solely by the general light bath. The speaker's experience was that light treatment did not prevent the onset of acute specific fevers, and in his own clinic the patients had suffered from varicella, measles, whooping-cough, and there had even been cases of cerebro-spinal meningitis. In post-febrile debility the treatment had great value. An experiment was about to be undertaken in one of the Metropolitan Asylums Board's hospitals of illuminating every alternate patient admitted for whooping-cough; some interesting information as to the value of light given during the course of an infection should be available in that way. With regard to pigmentation, he had seen good results in extensive lupus in patients who had not pigmented at all. The question of the area of the body which was to be exposed to light required further investigation. Dr. Sequeira also mentioned the extraordinary value of general light baths in the treatment of some of the more chronic affections of the eyes, especially in children.

Dr. KATHERINE GAMGEE said that children under 5 reacted very differently from older children, with whom the reaction was very much the same as in the case of the adult. With regard to rickets, she had had experience of some severe cases, which had made apparently no headway under cod-liver oil treatment, and took a sudden leap forward when put on light. The nervous child reacted in an extraordinary way, and, in particular, cases of nocturnal enuresis showed a marked response. An analysis of about twenty or thirty cases showed that the percentage of cures was slightly higher with this form of therapy than with other forms, though she knew that it was difficult to formulate any conclusion from so small a series. The convalescent child and the child about to be submitted for operation for tonsils and adenoids offered very suitable cases for treatment. Light treatment shortened convalescence. The results in anterior poliomyelitis she had found very disappointing unless the child was submitted to the treatment very early. To her mind the remarkable thing about light treatment was that the body cells became unresponsive with extreme ease; this was quite apart from any phenomenon of pigmentation, and occurred in children who did not pigment.

Dr. A. C. ROXBURGH thought it almost impossible to make a fair comparison between the values of natural and artificial light, for the reason that sunlight treatment must necessarily be given in the open air, whereas the carbon arc, or any other form of arc, had to be given in a comparatively stuffy room, because any draught upset the work. Thus the comparison between the two sources was vitiated. Many speakers had referred to light treatment as non-specific. This was borne out by an analysis of the statistics of cases treated at St. Bartholomew's Hospital during twenty-one months. There were 272 cases, and the curious thing was that whether one took tuberculous infections, non-tuberculous infections, or non-infected cases, the proportion of cases cured or greatly improved in each of the three groups was round about 20 per cent. In the cases which were somewhat improved the proportions were rather different—namely, 36 per cent. of tuberculous infections, 57 per cent. of non-tuberculous infections, and 48 per cent. of non-infected cases. Of all the cases treated, 21 per cent. showed cure or great improvement, 46 per cent. some improvement, and 33 per cent. were not improved or were made worse.

Mr. L. V. CARGILL endorsed Dr. Sequeira's remark about the value of general light baths in the treatment of chronic affections of the eyes. He had found general carbon arc baths give good results in conjunctivitis and keratitis and tuberculous diseases of the eye. Such conditions as detached retina could not be benefited, which, of course, had had to be denied.

CHEMOTHERAPY.

AT a meeting of the Section of Comparative Medicine of the Royal Society of Medicine, held at the society's house, 1, Wimpole Street, on March 16th, at 5.30 p.m., the President, Sir D'ARCY POWER, in the chair, Professor MOELLGAARD of Copenhagen read a paper on "Some of the principal questions in chemotherapy, with special reference to the heavy metals."

Professor Moellgaard began by saying that, according to the usual modern conception, specific therapy was identical with immunotherapy; in other words, that the therapeutic agent was the metabolism of the animal organism itself, and that it attacked the invading parasite only, leaving the sound host-tissue untouched. In this respect the immunological power of the host undoubtedly represented the ideal form of therapy. In many cases, however, this power failed to cure the disease, even when general or vaccine or serum treatment was given also, because either the host could not produce this curative power in sufficient quantity or because its action on the parasite was prevented from becoming effective. In these cases an attempt must be made to alter the dominating pathological conditions of the host, either by removing the cause of the failure of the development of these powers, or by attempting to destroy the parasite itself. Both of these possibilities had been considered by scientific chemotherapy from its origin in the work of Ehrlich. The purpose of chemotherapy was to discover substances which caused, directly or indirectly, the maximum amount of harm to the parasite with the minimum amount of injury to the host. So far, no substance had been discovered which, having a considerable effect on the parasites, was at the same time harmless to the host, and present knowledge of the relationship between chemical composition and the pharmacological action of drugs was too slight and fragmentary to enable such substances to be prepared. Accordingly, chemotherapy was at present, and would remain for many years, a series of approximations to the ideal type of therapy which was created by the natural powers of the animal body itself. This was evident by the fact that the real worth of any drug in present use might seriously be doubted, because its influence was never limited to a certain parasitic organism, but often extended to many different species. Accordingly, the action, even of the best of these substances, seemed to be due to general chemical affinities. Ehrlich's original conception was "*corpora non agunt, nisi fixata*," or that the action of chemical substances on the living cell was subject to the existence in such substances of chemical groups or radicles susceptible of reaction with other chemical groups in the cell. This rule, the basic principle of our whole idea of metabolism, was generally accepted. On the other hand, the conclusions Ehrlich drew—namely, that a parasite could only be killed in the host by chemical compounds having a special chemical affinity for its protoplasm (in other words, a pronounced *parasitotropy*), could not be accepted as a correct interpretation of the known facts. In the first place, they failed to account for the fact that the drug did not react on the parasite merely in a watery solution, but was injected into a very complicated heterogenic system, the animal body, where it underwent chemical changes which might al its therapeutical action. Secondly, experience seemed indicate that chemical compounds might kill the parasit not by reacting on them, but by stimulating the natu reactions of the host. This might be of very great imp tance to the future development of chemotherapy, beca it meant that not only were they dealing with the chemi substance and the parasite, but also with the react tissue of the host. Browning had expressed this epigra matically when he said that chemotherapeutical substan reacted in co-operation with the tissue.

Professor Moellgaard then proceeded to consider the m important modern researches in chemotherapy and the li which they threw on this co-operation. The drugs he de with fell into two groups: the salvarsan and sanocry series and the trypaflavine series. Sanocrysin, when gi subcutaneously, was relatively effective, whereas lo applications were ineffective. The reverse was true trypaflavine, whose local action was much more effecti

in destroying the parasite. He also drew attention to the effect of sanocrysin in tuberculosis. When laboratory animals were treated with this salt four to five days after infection, about 95 per cent. recovered; if the injection was during the second week, the cases which recovered amounted to about 75 per cent.; while if the drug was given at the same time as the bacillus, even though it was repeated later, none recovered. This seemed to suggest that it was necessary that the disease should commence before treatment was applied. He then considered in detail the theory of Ehrlich, and the modern theory of the catalytic action of these substances, and related his own recent experiences with chemotherapeutical agents.

ULTRA-VIOLET RAY THERAPY.

AT a meeting of the Forfarshire Medical Association at University College, Dundee, on February 16th, the President, Dr. R. C. BUIST, in the chair, Dr. G. H. S. MILLN opened a discussion on heliotherapy.

Dr. Millin first surveyed briefly the history of heliotherapy, and then gave a short account of the general properties and physiological effects of the ultra-violet rays. Describing the commoner modes of production of the rays, he said that those from the tungsten arc were probably the best for light treatment. The dosage depended on the patient, on the lamp, and on the distance of the light from the skin. The susceptibility of patients could be tested by exposing small areas of skin to various doses, and determining the dose required to produce erythema. He believed that it was best to begin with just under an erythema dose, and then to increase it gradually until eventually a good brown pigmentation was acquired. The effects were those of an ideal tonic. Remarkable results were obtained in those patients who, while never well, yet showed no definite sign of disease. Ultra-violet radiation was also one of the most potent weapons that the dermatologist possessed. Combined with x rays he had found it of great value in sycosis. In carbuncles and in furunculosis the results of ultra-violet radiation were almost uncanny, but psoriasis did better with x-ray treatment. In the case of tuberculosis of the skin x rays had now been practically discarded for ultra-violet rays, but caution was necessary since vascular dilatation round foci in the lungs might lead to sudden haemorrhage. In rickets, ultra-violet treatment, together with proper feeding, exerted a great influence. In bronchitis and asthma the results were striking. Tuberculous glands without softening were much benefited, and definite improvement followed when sinuses were present. In fibrositis and allied conditions great success was obtained by a more drastic application, a fairly sharp reaction being aimed at. Claims were being made for ultra-violet rays in almost all diseases, but it would be well to see that this most beneficial form of treatment did not fall into disrepute through exaggerated statements.

Dr. J. HUNTER discussed the use of ultra-violet rays in the treatment of tuberculosis, and described the methods employed and the results obtained in three institutions in Dundee. He emphasized the point that this potent agent must be used with caution in the treatment of tuberculosis, or a latent lung focus might be roused with disastrous results. He favoured the open carbon arc. The best results were produced by general radiation; erythema and pigmentation should not be produced. Good results were obtained in the case of the pre-tuberculous child. Abdominal tuberculosis generally did well, but in tubercle of bones, joints, and spine the effects were not good. He had used the rays carefully and under rigid rules in lung cases in a moderate state of activity. No bad results had been found so far, but he could not say that good results had been obtained. There might be general improvement, but he had found no improvement in the local lesion.

Dr. J. B. MACDONALD read notes on six months of sunlight lamp work in Dundee Eastern Hospital. With the mercury vapour lamp he had obtained marked improvement in marasmus and rickets. Varicose ulcers as a rule did well. Among the cases which appeared to have benefited, and of which notes were read, were rheumatoid arthritis, chorea, epilepsy, and mental depression.

Dr. JOHN KINNEAR remarked on the similarities in causation and treatment between tubercle and rickets. He suggested that ultra-violet radiation of cod-liver oil might be tried in tubercle as well as in rickets. He reported a case of summer eruption due to sunlight; it was cured by small doses of ultra-violet rays.

Dr. ROGERS agreed that great improvement followed the use of the rays in rickets. Herpes zoster was benefited, and excellent results were obtained in erysipelas. He had found the treatment useful in marasmus and as a tonic after pneumonia.

Dr. A. R. MOODIE discussed the applications of heliotherapy in ophthalmology. Many conditions, such as chronic blepharitis, trachoma, and marginal ulcers, did well under this treatment, but interstitial keratitis did not respond. Local phototherapy to the eye was not without danger and should be used only by an ophthalmologist with a thorough knowledge of ultra-violet rays.

The PRESIDENT said that the discussion showed that while the method was very attractive from an empirical point of view, it was from the scientific standpoint a mere infant and was open to the serious risk of improper exploitation.

HEART DISEASE AND PREGNANCY.

AT a meeting of the Midland Obstetrical and Gynaecological Society on February 8th, the President, Mr. FURNEAUX JORDAN, in the chair, a joint discussion on heart disease and pregnancy was opened by Dr. J. G. EMANUEL (Birmingham).

Dr. Emanuel mentioned the great diversity of opinion as to the seriousness of heart disease in pregnancy, the mortality rate being variously stated from 3 per cent. to over 60 per cent. The only form of heart disease likely to affect cardiac efficiency during the child-bearing age was rheumatic heart disease, and mitral stenosis, with or without aortic disease, was the commonest form. The incidence of rheumatic heart disease in pregnant women was roughly 1 per cent. The cardiac output in cubic centimetres per minute during pregnancy had been found by experiments in animals to be increased by one-third to one-half the output before pregnancy; while the reserve power of the normal heart was able to meet this extra load, the damaged heart was liable to fail. There was no evidence of hypertrophy of the heart or of increased blood pressure during normal pregnancy. Even were it possible to estimate mathematically the reserve power of the heart by exercise tolerance tests, this alone would not indicate the effect of pregnancy on a damaged heart. Such an estimate would only give a measure of the mechanical strain the heart was able to stand, whereas cardiac failure might also be brought about by unpredictable factors such as an intercurrent infection, including the common cold, influenza, and endocarditis, the onset of auricular fibrillation, the occurrence of embolism, difficult labour, puerperal infection, and the toxaemias of pregnancy. Rhythm and the size of the heart were the most important guides in prognosis. Sinus arrhythmia and extra-systoles were of no importance, but auricular fibrillation was a bar to pregnancy. If the heart was not enlarged the risk of mitral disease was small, but the risk increased with the degree of enlargement of the heart, and these facts were well supported by the statistics of the late Dr. G. H. Hunt in the *Guy's Hospital Reports* for April, 1926. While it was difficult to say in what cases of heart disease pregnancy was comparatively safe, it must be clearly recognized that pregnancy and repeated pregnancies were possible without ill effects in women with rheumatic hearts. A woman with cardiac disease, but no symptoms of diminished reserve power, might be allowed to become pregnant, but when a woman with heart disease had shown objective evidence of cardiac failure, pregnancy must be avoided. If signs of cardiac failure supervened during pregnancy the patient must be treated as a case of heart failure, and by the same methods as though non-pregnant. Cardiac failure might occur after delivery, showing that emptying of the uterus was to treatment for a failing heart. Only when the cardiac failure had been successfully combated should interference with the pregnancy be considered, and this question would

be greatly influenced by the date of pregnancy, the financial position of the patient, and her ability to obey instructions. If the cardiac failure occurred early in pregnancy induction of abortion was required, but if it occurred in the later months, and provided that strict supervision and suitable treatment were possible, the delivery of a living child by Caesarean section followed by sterilization should be aimed at.

Dr. F. EDGE recalled the death of a woman with mitral stenosis during the second stage of labour which he reported in 1890. In those days Caesarean section and induction of premature labour were comparatively risky procedures, and the method then employed in heart disease was to evacuate the uterus in the early months or to help labour by forceps or version under an anaesthetic in the later months of pregnancy. That the heart was adversely affected by pregnancy was especially shown by the congestion at the bases of the lungs, the oedema of the limbs, and the varicosity of the veins. In a case of heart disease with an evident defect in compensation the patient should be advised against marriage; if she was married contraceptive measures might be legitimately ordered and taught. When pregnancy occurred with a defective cardiac condition the simplest means of combining evacuation and sterilization was a subtotal hysterectomy with preservation of the ovaries. This method assured the patient against pregnancy, and enabled happy married life to be continued. At this stage it was an easy and uncomplicated operation. During the later months, as soon as the child was viable, Caesarean section under a general or spinal anaesthetic should be performed. Induction of premature labour was not advisable in these cardiac conditions except in the most favourable cases. A competent cardiologist should have charge of these patients, and on his direction the obstetrician should act according to the duration of the pregnancy.

Mr. CHRISTOPHER MARTIN raised the question whether a woman with organic heart disease and good compensation should be allowed to run the risk of pregnancy. He thought that the danger of failure of compensation was so serious that in most cases it should not be permitted. The patient should be told the danger, and if she decided to run the risk the responsibility was hers. If it was ever justifiable to advise methods of contraception it could be approved in such cases as these. Though many cardiac patients passed safely through pregnancy and labour, certainty of this was not possible. In dealing with patients with definite organic heart disease in the first half of pregnancy, while there might be no present signs of compensation breaking down, yet they could not answer for the latter half of pregnancy. Some patients passed through the whole course of pregnancy and the strain of labour without any difficulty, but the majority of cases he had seen did not do so. Commencing failure called for intervention, but in the absence of such signs it was permissible to treat the case medically and wait for danger signals, though it must be remembered that these might come on without warning and active measures be taken too late. The more advanced the pregnancy the more risky was intervention, especially after failure of compensation. Treatment of patients with organic heart disease in the latter half of pregnancy depended on the general condition. If compensation was failing there should be no long wait before intervening; if it was good then it was justifiable to wait till near full term in order to give the child a fair chance of life. In the first half of pregnancy abortion was best induced by inserting one or two solid rubber bougies about the diameter of a lead pencil into the uterus. They were better and safer than the gum-elastic catheter often advised, since they could be boiled. No anaesthetic was required. The vagina was cleansed, disinfected with tincture of iodine, the cervix drawn down with volsella, and the perineum pulled back with a speculum. It was now easy to insert the bougie without letting it touch any part of the vaginal wall. Mr. Martin usually inserted one bougie four or five inches into the uterus, and tried to pass it between the ovum and the uterine wall without rupturing the membranes. In from twenty-four to forty-eight hours as a rule the uterus emptied itself. In some cases ovum forceps and the flushing curette might be required. In the latter half of pregnancy labour might be induced by inserting similar but larger solid rubber bougies, about half an inch in diameter. These were sterilized by boiling, and inserted by the same method as the smaller ones. It was sometimes necessary to dilate the cervix first with metal dilators (modified Hegar's dilators) in order to insert the rubber bougie. After the eighth month, and with a good prospect of the child surviving, the best line of treatment was Caesarean section, performed for choice under spinal anaesthesia. A woman with compensated organic heart disease who had safely gone through a labour at or near the full time should be advised to avoid a second pregnancy. If in such a case a Caesarean section was performed the Fallopian tubes should be tied in order to prevent further conception.

Dr. K. D. WILKINSON (Birmingham) said that they were dealing with women between the ages of 20 and 45 whose heart disease was the result of rheumatism. The commonest valvular lesion was mitral stenosis, which resulted from prolonged rheumatic infection and was often associated with damage of the heart muscle and kidneys. No woman who had once had heart failure should risk pregnancy. No woman with auricular fibrillation or heart-block, or history of rheumatism, or considerable cardiac enlargement, with or without valvular disease, should be allowed to become pregnant. On the other hand, valvular disease of the heart did not invariably forbid pregnancy, and pregnancy was permissible when the damaged valve was in a stationary condition and of long standing, if the response of the heart was good, if there was little or no enlargement, if the excitability of the heart was not raised, and if the rhythm was normal. It might also be allowed in aortic regurgitation where the arterial pressures were approximately normal, and in mitral stenosis if the presystolic murmur was short, the pulse volume good, and there was no enlargement of the liver or oedema of the lungs. When a woman with heart disease became pregnant her social condition was very important in determining what steps should be taken, since it was obvious that a woman in good circumstances could rest and adopt the treatment advised, when her poorer neighbour was unable to do so. The first child was often the most difficult, both during pregnancy and at labour, yet, on the other hand, the first child was the most desired. The risk to the child was greatly increased by heart failure in the mother, and the risk to the mother was not only increased by pregnancy, but also by the necessary care of the child, which was the mother's duty, at least among the poorer classes, for a year or more after birth. These cases should be seen as soon as possible, diagnosis should be made early, and a settled opinion reached as to the treatment. When the heart had failed, the failure must be treated first and then the pregnancy. Dr. Wilkinson preferred delivery by Caesarean section because a short anaesthesia added little to the danger, the fatigue of labour was avoided, plethora could be minimized, sterilization was possible, and the time of operation could be accurately selected, thus avoiding the tedious last month of pregnancy. During pregnancy there was extra blood to be distributed throughout the body and there were various disturbances which were normal in pregnancy. Sooner or later a woman without any heart disease showed some dyspnoea and a lessened physical capacity for exercise. Often the presence of varicose veins or oedema suggested pelvic pressure, and these signs were much more common and much more serious when there was defective cardiac reserve. Pregnancy was cumulative in its effects, and not only did the cardiac work increase but the metabolism of the whole body was increased as the gestation advanced. Because of the raised diaphragm, respiration became less efficient, and to these must be added the effects of labour. His experience had convinced him that pregnancy had a harmful effect upon a damaged heart. In many cases it accelerated the final failure of the heart, while in all cases the heart afterwards was not quite so good as it was before. Mitral stenosis appeared to him the most serious lesion, for he had now seen eight deaths from acute pulmonary oedema in women with mitral stenosis, all of which occurred during or immediately after labour.

Professor LAURENCE BALL said that when a woman with heart disease became pregnant they had to attempt to estimate the reserve power of the heart, and to consider whether it was adequate to meet the unusual stress which would shortly be imposed upon it. The medical question could not be considered apart from the obstetrical; the probability or otherwise of an easy labour had obviously an important bearing, but unfortunately both factors could only be estimated roughly. A single examination of the circulation in these cases was entirely unsatisfactory; the heart required careful supervision throughout the duration of pregnancy. They were to some extent handicapped by inadequate knowledge of the physiological changes which occurred in the circulatory organs during pregnancy and in labour. During pregnancy for various reasons the heart was called upon to do extra work; there was thus normally a dyspnoea on effort in the later months. When estimating the reserve power of the heart early in pregnancy it must be remembered that the field of response to effort would be diminished later, and that only a part of the reserve found at an early stage would be available to meet the stress of labour. He had never seen pregnancy associated with heart disease of purely vascular origin, arterio-sclerotic or syphilitic. In cases of renal disease with cardiac enlargement the renal element was more important than the cardiac from the obstetric point of view. Irregularity of the heart due to extra-systole occurring apart from signs of organic disease would not interfere with a normal pregnancy and labour. He had seen a case of Graves's disease in which all the symptoms, including tachycardia, became aggravated during pregnancy, and it was considered advisable to terminate the pregnancy at an early stage. In one case of paroxysmal tachycardia of undetermined nature the paroxysms were severe and prolonged, and associated with crepitations at the bases of the lungs, and again it was considered advisable to terminate the pregnancy. Recently, however, he had seen a woman who had suffered for over twenty years from paroxysmal tachycardia and had borne two children without difficulty. While such conditions as these were relatively rare, rheumatic disease was common, and the most frequently occurring lesion was mitral stenosis. In each case they must attempt to estimate the reserve force of the heart, bearing in mind what the effects of the stress of the later months of pregnancy, of labour, and the puerperium were likely to be. The significance of murmurs must be considered and the size of the heart noted; the pressure, rhythm, and rate of the pulse, the response of the patient to effort, the presence of cyanosis, oedema, albuminuria or swelling of the liver, and the occurrence of persisting crepitations at the bases of the lungs demanded consideration. In a case in which the systolic murmur of mitral regurgitation was present the cardiac enlargement was inconsiderable, the cardiac rhythm was regular, there was no cyanosis, and the patient's response to effort was good, the pregnancy should proceed to a natural termination. Pregnancy was dangerous in the case of a young patient pregnant for the first time if she had poor general physical development and a history of repeated manifestations of rheumatic infection in childhood, with the murmur of mitral regurgitation, a much enlarged heart, cyanosis, and poor response to effort. When the apical murmur was presystolic in time, with or without a systolic murmur, the rhythm was regular, cardiac enlargement inconsiderable, cyanosis absent or minimal, and the response to effort good, the signs indicated an early stage of mitral stenosis, and such a patient might be expected to bear her child without harm. In a more advanced stage of mitral stenosis the patient was definitely cyanosed, there was dyspnoea on effort and evident cardiac enlargement. On auscultation at the apex, in addition to a presystolic murmur, there was a long diastolic rumble, and the second sound at the pulmonary area was accentuated. Such a patient frequently gave a history of haemoptysis, not in itself a serious matter; of much greater significance was the presence of persisting crepitations at the bases of the lungs, and especially if associated with impairment of resonance and weakness of breath sounds. This group presented the greatest difficulty. If such signs were found at an early stage of pregnancy, Professor Ball thought termination of the pregnancy was always justifiable, but they often appeared late in pregnancy. In determining the course of action at this stage, especially in the case of women of the working class who had usually been up and about until the time of admission to hospital, in all but the urgent cases it was useful to try the effect of rest in bed upon the symptoms. He had seen several patients in whom symptoms of serious cardiac failure had improved with rest in bed to such a degree as to allow of spontaneous labour or Caesarean section at or near term. The danger of allowing such cases to proceed to term lay in the risk of a rapid development of pulmonary oedema. Increasing cyanosis and an upward spread of crepitations from the bases of the lungs were ominous signs. From the obstetric point of view, and as regards the immediate future of the patient, he had not observed any essential difference between those cases of mitral stenosis in which the heart failed with fibrillation and those in which it failed with a regular rhythm. If fibrillation was found early in pregnancy, generally the pregnancy should be terminated; if it occurred late, the other procedures previously mentioned were permissible. He thought he had seen more favourable results in failure with fibrillation late in pregnancy than in failure with a regular rhythm, owing to the better response to digitalis. He had seen three cases of the association of pregnancy with aortic regurgitation. In all these mitral lesions were present as well, and in two the mitral lesion appeared to be the more important; in none of them was the pregnancy allowed to proceed. In the more definitely aortic case there was great dyspnoea, and the character of the pulses and size of the heart pointed to a severe incompetence; this patient did not long survive the evacuation of the uterus. The termination of the pregnancy in these cardiac patients did not leave the heart as it was before conception. Prolonged rest and continued medical treatment were required, and there was a great tendency to permanent impairment. He had known patients too often come well through the delivery only to break down again on the premature resumption of household duties.

JAMES MACKENZIE INSTITUTE.

Haemoptysis.

AT a meeting on February 8th Dr. W. B. MACTIER dealt with the problems of blood spitting. He reviewed first the more common causes of haemoptysis—namely, phthisis and mitral stenosis—and gave details of two cases from the Institute records, in both of which the haemoptysis was often repeated, to exemplify its occurrence in mitral stenosis. Dealing with the rarer causes, the lecturer included in this group pneumonia, infarct, and bronchiectasis, describing a case of unresolved pneumonia complicated by infarction of the lung, and also a case of bronchiectasis, to illustrate its occurrence in these conditions. He specially directed attention to an interesting group of cases of haemoptysis from the records, in which, after prolonged observation, it was still not possible to be certain of the cause of the condition. All the patients had been carefully followed up since the haemoptysis, both clinically and by x-ray examinations, but nothing had come to light to clarify the diagnosis. In regard to the significance of haemoptysis, he indicated the great difficulty of correctly assessing this symptom in apparently healthy people, the most pressing question in the minds of both patient and doctor being whether or not the condition afforded evidence of phthisis. The lecturer drew attention to the difference of opinion among clinicians in regard to this, and mentioned that some authorities still asserted that probably all cases of haemoptysis were tuberculous in origin. Gee had suggested the possibility of recurrent haemoptysis being due to the presence of a small cavity "perhaps no bigger than a cherry." Dr. MacTier reported two cases which appeared to be of this nature; in neither had the tubercle bacillus been found on repeated examination. Prognosis in haemoptysis was primarily a question of diagnosis, the most difficult cases being those of healthy young adults who showed no physical signs of disease. The importance of continuing accurate observations of the weight, the evening temperature, and the sputum over a prolonged period was emphasized.

Reviews.

PLANT POISONS AND STIMULANTS.

Inorganic Plant Poisons and Stimulants,[1] by Dr. WINIFRED E. BRENCHLEY of the Rothamsted Experimental Station, first appeared in 1915, and in the second edition, which has just been published, the scope of the work has not been altered, though the text has been brought up to date by the inclusion of recent research work.

The action on plants of salts of copper, zinc, arsenic, boron, and manganese is described in detail. The facts are, of course, of great practical importance to farmers for their guidance in the use of chemical manures and fungicides, but it is of general interest to physiologists also, since many of the results show important analogies to effects observed in animal physiology. For example, a solution of copper in pure water exerts a powerful oligodynamic toxic action, and one part per million of copper sulphate stops all growth of barley, but if neutral salts are present ten times this concentration is needed to produce the same effect.

Even more interesting is the evidence that traces of boron and manganese are necessary for the normal development of plants. The quantities necessary are extremely small, for a concentration of one in one hundred million of manganese can produce a distinct stimulant action in the growth of barley. The similarity between these effects and those of iodine lack on vertebrates is at once obvious.

It is instructive to note that the author's careful analysis of the evidence shows that the action of these metals on plants does not really support the so-called law which states that substances which produce a toxic action in high concentrations will also produce a stimulant action in low concentrations. It is true that traces of boron and manganese are essential for the normal growth of many plants and that these substances are toxic in high concentrations, but, on the other hand, copper, arsenic, and zinc in most cases are toxic in all concentrations at which they produce any measurable action.

These examples show how many points of interest to general physiology are brought out in Dr. Brenchley's work.

INDUSTRIAL MEDICINE.

THE first volume of a new German treatise of social hygiene[2] was reviewed in our columns on November 6th, 1926 (p. 838); the second volume is wholly devoted to industrial medicine. Special attention is given to clinical aspects which, the editors remark, have not received adequate notice in German medical literature.

The first two hundred pages of the volume are on general questions. In this section the article of most interest to the English reader is Brezina's discussion of Taylor's system ("Scientific Management"), hours of labour, rest pauses, and night work. There follows a short and not very satisfactory statistical article by Koelsch; it is not very satisfactory because the best German statistical material dealing with sickness rates, that of the Leipzig Insurance Bureaux, is now almost a quarter of a century old, but must still do duty as no similarly detailed analysis has since been prepared. However, no Englishman can cast a stone, because nothing so detailed has ever been done in this country. The next 140 pages are devoted to industrial poisoning. Physical agents are then examined; Mager's section on caisson disease—a subject to which much attention has been paid by English physiologists—although concise is adequate. We then have a series of articles upon diseases peculiar to or most frequent in particular industries, classified, in the main, anatomically. Mendel's essay on diseases of the nervous system, which discusses also occupational neuroses, is worthy of special mention, and Oppenheim's section on diseases of the skin is very well illustrated. In Koelsch's paper on cancer in occupations there are some interesting notes on the remarkable incidence of cancer of the lung upon the cobalt-arsenic miners of the Schneeberg district of Saxony; how far direct mechanical irritation and how far specific chemical action may be involved are unsolved problems. The volume concludes with a series of articles on the hygienic conditions of the chief industries in Germany. Schürmann's account of coal mining, illustrated by very full statistics of Rhenish-Westphalian coalfields, is particularly valuable. It appears from these tables that the incidence of fatal accidents is much heavier than upon any of the English coalfields, but the classification of workers may be different, and, therefore, the rates may not be comparable.

This should prove a useful textbook for the German hygienist; it contains some articles which can profitably be consulted by a foreigner; we have mentioned some of these, and may say generally that a comparison of the industries which are very important both in Germany and our own country is instructive. An interesting point is that some causes of incapacity which are very important here seem much less so in Germany. Thus telegraphist's cramp, the object of very special consideration here, is only noticed cursorily among a whole series of occupational neuroses, while miner's nystagmus is clearly much less prevalent as an incapacitating illness in German than in British mines. Perhaps both the general social distress in the years immediately following the war, and the fact that by the German law the onus of proof is upon the employee to establish the occupational origin of his incapacity, are factors of etiological importance when we are dealing with disability which has, at least, some psychological element.

Considering the greater length of our industrial history, it would be discreditable to the English medical profession if a foreign textbook were decidedly superior to anything of the kind in English. That is not, we think, the case. The English or American speaking student who is not a specialist need not go beyond works in his own language. This volume will, however, be a useful but—at £2 14s. unbound—rather expensive addition to a reference library.

THE ALPINE CLIMATE.

DR. PAUL GÖTZ carries on at Arosa an observatory on the lines of that at Davos conducted by Dr. Dorno. He has recently published a book detailing the results: *Das Strahlungsklima von Arosa*.[3] The duration of the sunshine, the total heat radiation of the sun, and the red, green-blue, and ultra-violet radiation are recorded daily; the cadmium photo-electric cell is used for the last. The effect of the transparency of the atmosphere, and of the ozone layer in the very high atmospheric region, are studied, the latter in association with Dr. Dobson of Oxford, who has initiated a world-wide investigation of the influence of this ozone layer on the ultra-violet radiation of the sun. It is this layer which limits the penetration of the shorter wave-lengths—to 2,900 Angström units. The brightness of the sky is also measured at Arosa, and the influence of different aspects on this. In addition to the ordinary meteorological data, wind, temperature, humidity, etc., the cooling power of the air has been studied by means of Leonard Hill's kata-thermometer. As at Davos, the cooling power is found to be very equable, owing to the absence of high wind.

The still cold air of winter, and the warmer breeze air of summer keep up about the same cooling power all the year round. This is of advantage in the treatment of tuberculosis. The high radiant energy and cool, still, dry, and dust-free air of the Alps offer most excellent conditions.

DISEASES OF THE HEART.

Auricular Fibrillation[4] was the subject chosen by Dr. EMANUEL for the Ingleby Lectures delivered at the University of Birmingham in 1925, and they are now published

[1] *Inorganic Plant Poisons and Stimulants.* By Winifred E. Brenchley, D.Sc., F.L.S. Cambridge Agricultural Monographs. Second edition. London: Cambridge University Press. 1927. (6½ × 9½, pp. ix + 134; 21 figures. 10s. 6d. net.)

[2] *Handbuch der Sozialen Hygiene und Gesundheitsfürsorge.* Herausgegeben von A. Gottstein, A. Schlossmann, L. Teleky. Zweiter Band: Gewerbehygiene und Gewerbekrankheiten. Berlin: J. Springer. 1926. (Sup. roy. 8vo, pp. viii + 816; 56 figures. R.M.54.)

[3] *Das Strahlungsklima von Arosa.* Von Dr. F. W. Paul Götz. Berlin: J. Springer. 1926. (6½ × 9½, pp. 190; 31 figures, 69 tables. R.M.8.70.)

[4] *Auricular Fibrillation.* By J. G. Emanuel, B.Sc., M.D., F.R.C.P. Birmingham: Cornish Brothers, Ltd. 1926. (Roy. 8vo, pp. 31; 16 figures. 3s. 6d. net.)

in a book. After a brief historical note the lecturer deals with the essential nature of this disorder of rhythm, and several parts which have been the subject of special observation are discussed in greater detail. The fact that in sinus rhythm all the impulses pass from auricle to ventricle, while in auricular fibrillation only a proportion do so is ascribed to the view that in the latter the impulses themselves are "abnormal" in so far as they arise from auricular muscle fibres and not from the pacemaker. No mention is made of circus movement or of the fact that increase in rate of stimuli attacking the bundle is in itself a cause of functional heart-block. In discussing the onset of auricular fibrillation, the author draws attention to a small group of cases in which reflex vomiting may be induced and can only be controlled by rest in bed or by restoration of sinus rhythm. The effect of toxins on the rate of the ventricle in auricular fibrillation is also discussed and their action in producing slowing of the ventricle rate is compared with the action of digitalis and of organic disease of the bundle, and the effect of all three in fibrillation is contrasted with their action on sinus rhythm. When dealing further with the effects of digitalis, the view is advanced, and supported by experiment, that the earlier effects of digitalis are vagal and the later on the bundle. The lectures provide suggestive reading, particularly in those parts where they differ from commonly accepted views.

During the great war the Surgeon-General of the United States Army issued Circular 21 as a guide to medical officers in the examination of the circulatory system of candidates for military service. Dr. LEROY CRUMMER, professor of medicine at the University of Nebraska, using this as his text, offers in his book the *Clinical Features of Heart Disease*[5] an interpretation of the mechanics of diagnosis for practitioners. Though rather discursive in its style, this book has much to commend it and should prove of value to practitioners in aiding them to assess the significance of the signs and symptoms of heart disease. It contrasts with many modern books on the same subject by reason of the entire absence of illustrations, and this is a natural corollary to a sentence in the text—"Overvaluation of mechanical aids in diagnosis is a general defect of medical thought." In the sections dealing with diagnosis and with treatment the author pays attention to many practical points often overlooked in textbooks. Some of his statements are rather arresting, as when he says that "simple aortic insufficiency in early adult life (not associated with mitral disease) usually develops during a pneumococcal infection and not during acute articular rheumatism"; and again, when he asserts that "cacodylate of sodium is a specific in rheumatic pericarditis." It is an easy book to read and contains many useful hints.

In his essay on *Angina Pectoris*[6] Professor HANS KOHN of Berlin gives a useful historical and critical review of the various hypotheses put forward to explain this condition. The discussion is concerned chiefly with the coronary and aortic hypotheses, and the author brings together a mass of evidence from all departments of medical science and practice for and against these views. As a result of this examination of the writings of previous workers and of his own experience, Professor Kohn comes to the conclusion that angina pectoris is always the result of narrowing of the coronary arteries. He believes that there is only one angina pectoris and that it is a definite disease, an entity, and not only a collection of symptoms. The coronary narrowing, in the great majority of cases, is anatomical (by atheroma, syphilis, etc.), but may, in a few cases, be purely functional and caused by coronary spasm, toxic or nervous in origin. He holds further that even with disease of the vessel wall, spasm gives rise to the attacks. The pain and the sense of oppression (which is but a variety of the pain) arise, and are experienced, in the coronary arteries and in the ischaemic heart muscle. He considers the sense of impending dissolution to be an expression of momentary cardiac failure as a result of the ischaemia, while sudden death occurring in an attack is due to ventricular fibrillation, also a result of insufficient blood supply. The review includes a bibliography of about five hundred references.

[5] *Clinical Features of Heart Disease.* By Leroy Crummer, M.D. Introduction by Emanuel Libman, M.D. London: Henry Kimpton. 1925. (Demy 8vo, pp. xix + 353. 12s. 6d. net.)

[6] *Angina Pectoris.* Von Prof. Dr. Hans Kohn. Ergebnisse der Gesamten Medizin IX. Berlin and Vienna: Urban and Schwarzenberg. 1926. (7¼ × 10¼, pp. 209-276.)

SIR JAMES CRICHTON-BROWNE'S ESSAYS.

IN *Stray Leaves from a Physician's Portfolio*[7] we welcome a further supply of the products of Sir JAMES CRICHTON-BROWNE'S spare moments in a long and observant life. Of these seventeen pleasantly written essays, many touch on medical subjects of general interest, such as "Dreamy mental states," "Poisons and poisoning," "Brain rest" (dealing with sleep), "Brain building" (with wise remarks on food), "Light and sanitation," and "Claret in Scotland," which contains also information about whisky. In several of the essays the life of students in the Scottish universities in the past is described, and a comparison between the less hardy condition of to-day indicated. Carlyle's experiences as a student form the subject of one essay and Craigenputtock of another. Biography is further represented by the story of Thomas Young's many activities, and by an article contending that Patrick Branwell Brontë has been much maligned and misunderstood. "Shakespeare in Scotland" contains much that is interesting, conveyed with a light touch, and showing his influence on the Wizard of the North. The rise of the drama in Scotland is traced, and the opinion is expressed that, in spite of what may be said to the contrary, the genius of that country is essentially dramatic. Among so much that is charming in these papers it is difficult to select one for particular mention, but perhaps that on "The lightening before death"—a quotation from Shakespeare: "How oft have men when at the point of death been merry, which their keepers call 'the lightening before death'"—deserves the palm.

THE WINE TRADE.

IN *Bottlescrew Days*[8] Mr. SIMON contributes another volume to the list of his publications on the subject which he has made his own. The title needs some explanation. The use of corks for stopping the mouths of wine vessels began with the eighteenth century, and at first the cork was made long and tapering so as to leave enough of it protruding from the neck of the bottle to allow a good grip with the fingers so that it could be pulled out. Before that time all wine was on draught in skins, casks, or jars. Then some genius had the bright idea of using short corks cut flush with the mouth of the bottle and protected by a layer of wax, and to extract these corks the bottlescrew, now known as a corkscrew, was invented. Like some other great inventions, this one is anonymous. The introduction of the cork and its screw enabled wine to be matured in bottle as soon as the bottles were made of a shape that allowed them to be laid down in the cellar. Much French wine was drunk in England in the days when Guienne belonged to the English Crown, and the traffic between Bordeaux and such privileged ports as Winchelsea was associated with the development of the British merchant navy. The huge cask or "tun" containing four hogsheads, or 252 gallons, gave its name to the "ton" of shipping measurement, for the size of a ship was gauged by the number of these great wine casks that she could carry. In Elizabethan times wines from Spain and its dependencies became popular, and Sherris (Xerez) sack and Canary (or Palm) sack figure largely in the drama of that period. French wines, however, seem to have become popular again in the seventeenth century, and despite tariffs and the long wars with France they never wholly lost their vogue, despite the Methuen Treaty of 1703, which was falsely accused of undermining the morale of Scotland.

> "Firm and erect the Caledonian stood,
> Old was his mutton and his claret good.
> 'Let him drink port,' the English statesman cried!
> He took the poison and his spirit died."

[7] *Stray Leaves from a Physician's Portfolio.* By James Crichton-Browne, M.D., LL.D., F.R.S. London: Hodder and Stoughton. (8¼ × 5¼, pp. viii + 251. 12s. 6d.)

[8] *Bottlescrew Days.* By André L. Simon, F.R.Hist.S. London: Duckworth and Co. 1926. (Demy 8vo, pp. 273; 46 plates. 21s. net.)

But the reputed death of the Scots spirit was, like that of Mark Twain, "greatly exaggerated." Perhaps the *perfervidum ingenium* was saved by whisky.

Mr. Simon is an enthusiastic admirer of French wines and has little to say in favour of those from other countries. Port, the rival of French wines for so many years, has few merits in his eyes. We hope that we do not misrepresent him in saying that he seems to think that good wine, and especially good French wine, is incapable of doing anybody harm. But the use of gin, which was encouraged at first in England because it was an indigenous production, is unsparingly condemned by him. We doubt very much whether the gin-drinking classes had ever been regular consumers of wine. Beer had been the popular beverage for centuries, and it was by favouring its consumption that the authorities tried to combat the evil habit of gin-drinking. In his condemnation of ardent spirits we are at one with the author, but we cannot share the conviction expressed in his dedication wherein drunkenness and teetotalism are referred to as evils apparently of equal magnitude, "which every fair-minded and temperate man cannot help deploring." While we would not "rob a poor man of his beer," we have yet to learn that total abstinence ever did anyone any harm, except the vendors of alcoholic liquor. Mr. Simon gives us a great deal of illuminating information as to the habits of the well-to-do in the eighteenth century, gathered from such documents as the wine accounts of the Barber Surgeons' Company of London, and of some great noblemen such as the Earl of Bristol. It is interesting to note the occurrence in such lists more than two hundred years ago of the names of vineyards such as Château Margaux and others which are still synonymous with excellence and popularity.

This book is profusely illustrated with forty-six plates many of them reproductions of old caricatures, others of excellent photographs of old wine glasses, bottles, and labels, besides reproductions in the text of bills and invoices. Among these latter is a trade card which has a peculiar interest for us. It is that of "John Lister Son-in-law and succefsor to the late Stephen Jackson, deceased, at the Old Wine and Brandy Vaults opposite Tokenhouse Yard," etc. This was the father of Joseph Jackson Lister, who carried on the business after his father's death, but whose heart was in the study of optics and who made most important improvements in microscopic object-glasses. His son Joseph was the great reformer of surgery who became Lord Lister. The great surgeon and man of science did not do credit to his father and grandfather in the matter of wine, if we may believe the story told of the unsparing denunciation of his claret by a tactless French guest in Glasgow.

NOTES ON BOOKS.

A SMALL *Handbook of Medical Electricity and Radiology*,[9] by Dr. J. R. RIDDELL, is stated in the preface to be written to inform the student as to the uses, and the indications for the use, of the many pieces of apparatus usually found in the electrical department of a general hospital. Into some two hundred and fifty pages of fairly large print, but small size, are compressed nine chapters and an index, together with about one hundred and ten illustrations. The subjects of the chapters are electrotherapeutics, the examination of the electrical reactions of nerves and muscles, Roentgen-ray production and control, the action of *x* rays on living tissues, *x* rays in diagnosis, *x* rays in treatment, radium, light, and carbon dioxide snow. The book is a well written example of its type, and it is rather extraordinary how much the author has been able to include and to compress into such a small space. Obviously a great deal of detail has of necessity been omitted. The eighty-seven pages allotted to regional examinations by means of *x* rays not only contain a vast amount of information, covering almost the whole ground of *x*-ray diagnostic work, but also many good illustrations. This chapter alone quite fulfils the intentions of the author as laid down in the preface. The book is well presented, the text is easily read and understood, and the illustrations are better than is usual in books of this kind. It can be recommended to students as a guide to the possibilities of an *x*-ray and electrotherapeutic department.

In the evening of life—at all events of a well spent life—a man tends naturally to become reminiscent. He reviews events in which he has taken part, and if he is of balanced judgement his mind recalls, not only his successes, but also his failures. The recollection of the latter need not be too bitter, for he knows that it is human to err; and if he feels called upon to record his experiences for the benefit of younger colleagues he is buoyed up by the hope that even his failures may not have been in vain. So it would seem to be with Dr. TYSON of Folkestone, who has recently published a small book of *Medical Notes*,[10] dedicated to his colleagues at the Royal Victoria Hospital. In fifty little chapters Dr. Tyson sets forth thoughts that have occurred to him on various problems in medical practice, and his words seem to flow gently from his pen, in defence of wise and balanced conservatism. Thus he does not despise the humble leech in the relief of heart congestion, and his list of valuable drugs is headed by magnesium sulphate. He finds that mercury still holds its own in the treatment of syphilis, and he has discovered that the drug, in the form of blue pill, has a soporific action in the insomnia of certain cases indefinitely described as biliousness. Dr. Tyson notes the difficulty at times of dissociating functional and organic disease. He regrets the lack of institutions where the general practitioner may keep early mental cases under observation on reasonable terms. He urges the need for instructing students in the use of as many of the instruments of diagnosis as possible, while recognizing that diagnosis should only be made after due assessment of the proportionate value of symptoms; and he pleads with the surgeon to remember the importance of treatment after operation, and to avoid, as far as possible, lightning diagnosis. In his final chapters Dr. Tyson discourses of the patient, what he shall be told, how he can assist us in his future treatment, how he should not be forgotten in treating his disease, whether he should be advised to remain long in bed, and when he should retire from his work.

There is good ground for believing that the number of members of the medical profession who take a lively interest in archaeology, using that term in its widest sense, is very considerable, and some have made themselves authorities on certain departments of field archaeology. It is probable, therefore, that numerous will be the medical readers of a new quarterly, *Antiquity*, for, judging by its first number, just issued, it will give a large part of its space to the results of field work. The present position of one subject to which medical men, including Dr. Williams-Freeman and the two Drs. Eliot Curwen, have contributed a good deal is stated in a paper on "Some Prehistoric ways" by Dr. R. C. C. Clay, F.S.A. The value of air photography in showing up old walls and paths now covered by ground under cultivation is well illustrated in one of the papers. The annual subscription is £1, which should be sent to the editor, Mr. O. G. S. Crawford, Nursling, Southampton. The first number has been very well printed by John Bellows of Gloucester, England, from whom single copies may be obtained (price 5s. 6d.).

The *Pharmacopoeia of the City of London Hospital for Diseases of the Heart and Lungs*, Victoria Park, contains three sections devoted respectively to medicaments for internal use; preparations for the throat, nose, larynx, eye, and ear; and external applications. An appendix contains instructions to sisters for the nursing of different types of patient, the special preparation necessary for *x*-ray examination, and the usual tables. The small volume (London: H. K. Lewis, 3s. 6d.) is interleaved with blank pages, and is of convenient size for the pocket.

The fifty-fourth annual issue of *Willing's Press Guide*[11] follows the lines of its predecessors, and is a useful work of reference. It contains an alphabetical list of newspapers and periodicals published in the United Kingdom, with particulars of the year of establishment, politics (if any), date of publication, price, and the publisher's name and address. An interesting list is provided of the existing newspapers and periodicals which originated in the seventeenth and eighteenth centuries. Lists are also given of reporting, telegraphing, and news agencies, and the principal newspapers published in the Dominions and in foreign countries. The present issue retains all the valuable features which have rendered past editions so popular.

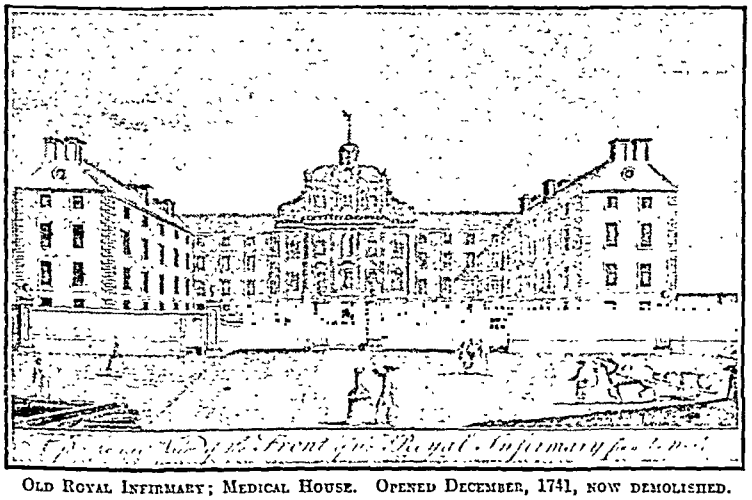
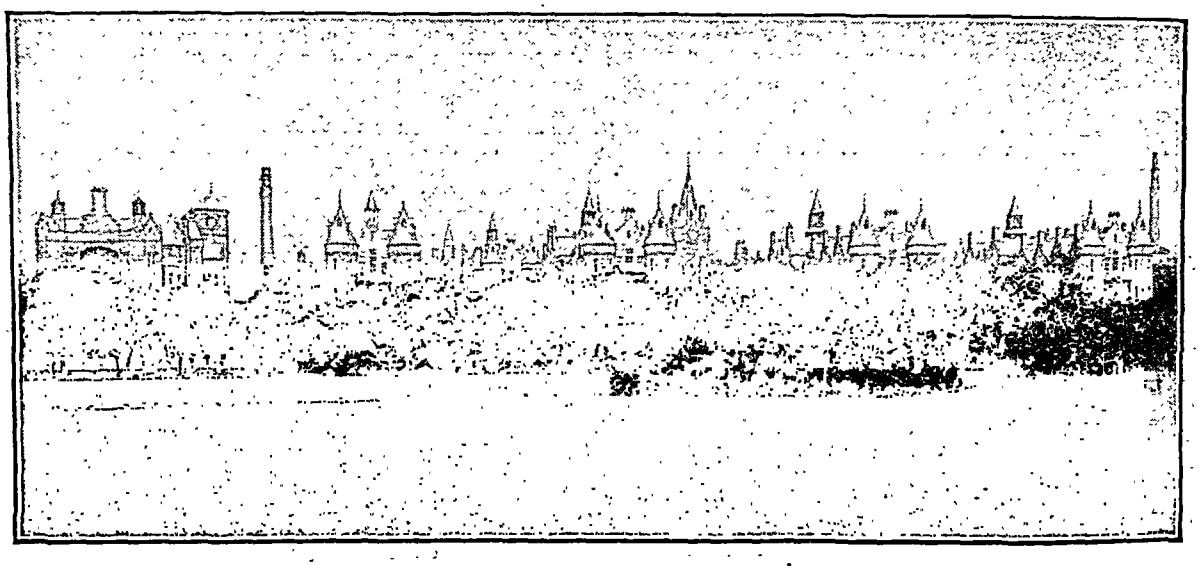
NINETY-FIFTH ANNUAL MEETING
of the
British Medical Association,
EDINBURGH, 1927.



THE ninety-fifth Annual Meeting of the British Medical Association will be held in Edinburgh this summer under the presidency of Sir Robert Philip, M.D., LL.D., honorary physician to the King in Scotland, who will deliver his address to the Association on the evening of Tuesday, July 19th. The scientific and clinical work of the meeting will occupy, as usual, the three following days, and on this occasion it will be divided among twenty-one Sections. The names of the officers of Sections and other preliminary announcements are published in the SUPPLEMENT this week; the full programme of scientific business and further details of the arrangements for the Annual Meeting will appear in later issues. The Annual Representative Meeting, for the transaction of medico-political business, will begin on Friday, July 15th. On the last day of the meeting (Saturday, July 23rd) there will be excursions to places of interest in the neighbourhood. We print below the third of a series of descriptive and historical notes on the Scottish metropolis and its relations with the science and practice of medicine. The first article, published on December 4th, 1926, dealt with old Edinburgh and the beginning of the Edinburgh Medical School; the second, on January 1st, with the Medical School from 1726 to the middle of the nineteenth century.

It has been decided to make the Edinburgh celebrations of the centenary of Lord Lister's birth coincide with the Annual Meeting of the British Medical Association. A book dedicated to Lister's life and writings is being prepared for the occasion, and throughout the week a museum of Lister relics will be on view in the Upper Library of the old University. On Wednesday, July 20th, at 8 p.m., a public meeting will be held in the McEwan Hall, with the Earl of Balfour, K.G., in the chair, when short commemorative addresses will be delivered.

EDINBURGH MEDICAL INSTITUTIONS.



THE ROYAL INFIRMARY OF EDINBURGH.

THE Royal Infirmary of Edinburgh owes its origin to the Royal College of Physicians, which was founded in 1681, largely by the influence of Sir Robert Sibbald, in association with other eminent physicians of the city, by whom the first steps were also taken for the foundation of a complete medical school at Edinburgh.[1] This College from its earliest days interested itself in the care of the sick poor, and at its third meeting, on February 10th, 1682, two physicians were appointed "to serve the poor of the city and suburbs." Advice and medicines were first distributed to the poor at the Hall of the physicians, but in 1725 the College proposed the foundation of a building where the sick could be received. In 1726 the minutes of the College mention that subscriptions had already been set on foot with "pretty good success," and the Fellows of the College were now joined in their scheme by the members of the Incorporation of Surgeons as well as receiving substantial encouragement from charitable people in many quarters. It was considered that the sum of £2,000 was the smallest which would suffice for this purpose, and this sum having been speedily collected, the committee charged with the object decided to hire a small house for receiving sick poor out of the annual proceeds of the capital sum, and at the same time appointed twenty managers to control it. This "small hired house" stood at the head of Robertson's Close and provided accommodation for six patients. It was formally opened on August 6th, 1729. Some time later the managers obtained a Royal Charter from King George II, dated August 25th, 1736, in which the hospital is designated the Royal Infirmary of Edinburgh, and by August 2nd, 1738, the foundation stone of a permanent hospital was ceremoniously laid. This building consisted of a "body with two wings, each of three full storeys and an attic one with garrets in the roof." The body was 210 feet long and each wing extended 70 feet, with a "large theatre where more than 200 students can see operations, and which is also a convenient chapel. Over the theatre a cupola is raised that may occasionally be used as an astronomical observatory, having windows to the different quarters of the hemisphere." The house was designed for 228 sick people "received into separate beds," and on the ground floor there were twelve cells for mad people. Round the hospital was an area of two acres with grass walks for the patients to walk in. The patients previously had had the privilege of walking in the neighbouring Physic Garden of the College, which had

OLD ROYAL INFIRMARY; MEDICAL HOUSE. OPENED DECEMBER, 1741, NOW DEMOLISHED.

[1] See BRITISH MEDICAL JOURNAL, December 4th, 1926, p. 1067.

ROYAL INFIRMARY, EDINBURGH, FROM THE MEADOWS.

been leased in 1724 to Dr. Rutherford and some of his colleagues for the purpose of rearing medicinal plants. The building of this hospital appears to have commended itself to all classes. The Assembly of the Church of Scotland ordered collections to be made at all church doors; benefit nights were given at the theatre; most of the societies in and about Edinburgh sent money; merchants sent presents of timber, stone, and other materials; farmers and carters supplied carriages; and mechanics and labourers gave so many days' work gratis. In addition, the managers dispersed copies of their prospectus in England, Ireland, and the British Plantations, from all of which countries considerable subscriptions were received. In the credit assigned to the founders of the hospital, one of the most active to be recognized was George Drummond, Commissioner of Excise, who held the office of Lord Provost of Edinburgh six times. "His indefatigable labours in procuring bounties, whether money or material, to set the work agoing and his ardent efforts in forwarding it when begun, were amply compensated, as his solicitous wishes were happily gratified, in seeing it completed many years before his death." The labours of this public-spirited and far-seeing man were commemorated by a bust which stands at the entrance to the present Royal Infirmary as well as by a portrait in the board room. Finally the Infirmary was fitted up, and the sick were received into it in December, 1741.

In 1745 and 1746 the affairs of the Infirmary, as well as of the whole country, were thrown into confusion by the Rebellion, and the Infirmary was converted into a general hospital for sick and wounded soldiers, of whom several hundred were attended and dressed by the surgeons. From the commencement of the hospital in 1729 the surgeon apothecaries had not only attended without fee, but each had furnished the medicines necessary out of his own shop. In 1748, however, the managers decided to fit up an apothecary's shop in the institution from which both in-patients and out-patients could be served.

By 1778, when a new appeal was issued, it had been found that the original twelve cells for mad people were unnecessary, and some of them had therefore been converted to other uses. On the upper floor a ward had also been established "for lying-in women, sufficiently separate from the rest of the house, and under the direction of the professor of midwifery." On the attic story and in a remote part of the house "a salivating ward for female patients had also been established containing twelve beds." There was also a small ward with four beds for the same purpose. "This ward was fitted up in consequence of a few female patients, who, being sufferers, not by any fault of their own, but by that of their husbands, or from suckling infected children, had applied to be taken under cure in the hospital." By this time, too, it is recorded that "in the west wing are one cold and two hot baths with their respective dressing-rooms, while in the east wing is a bath for the patients of the house, so constructed that it may be occasionally used either as a cold or a hot bath." The report continues: "those in the west wing are intended for people of the city; no patient in the hospital having at any time admittance to them." These three baths appear to have been the only provision, towards the end of the eighteenth century, by which the inhabitants of Edinburgh could carry out complete ablution otherwise than in a stream or in the sea, and the baths appear to have been a source of considerable revenue to the charitable institution. Another source of revenue was tapped in 1746, when the managers of the Infirmary and of the town's workhouse took a joint lease of the hall where the weekly assemblies for dancing were held. Several ladies of quality and rank undertook to act in turn as directresses of the weekly assemblies, and the profits arising from these brought to the Infirmary a revenue of about £100 per annum.

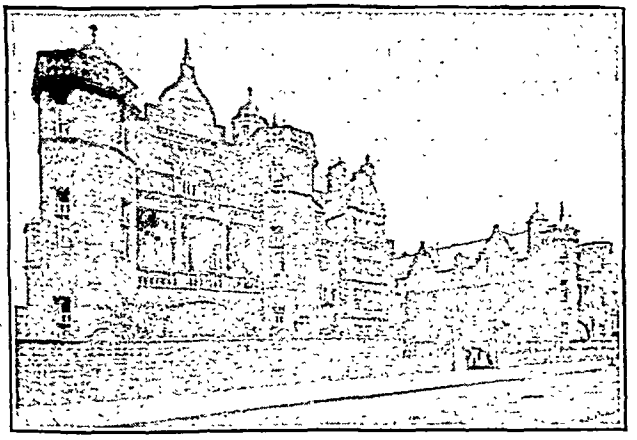
It is interesting to note that the Royal Infirmary of Edinburgh in the eighteenth century affords an example of the modern movement for the payment of hospital staffs. In January, 1751, the managers elected Dr. David Clark and Dr. Colin Drummond physicians in ordinary to the infirmary, each with a salary of £30. This was to supersede the old arrangement by which each of the Fellows of the College of Physicians had in turn attended the Infirmary for a month, but this arrangement seems again to have been departed from at a later period. For a time also the practice of having paying patients was introduced, and the charge for these was at the rate of 6d. a day. After the peace of 1763 a great number of sick and lamed soldiers presented themselves at the Infirmary, and in the same year Dr. Adam Austin was appointed by the Commander-in-Chief to visit the military wards regularly and to report thereon. Every assistance was given by the managers and staff of the house to Dr. Austin in the execution of these duties.

Excluding the military ward and the wards reserved for special types of case, some sixty beds appear to have been available for ordinary free patients. With these the Infirmary continued for about half a century, but in 1828 the old High School, vacated by the transference of that institution to a site on the Calton Hill, was acquired, and this, along with an intermediate building connecting it with the original Infirmary structure, became the surgical hospital. This part of the old Infirmary is still standing, though the original building of 1741 has long since disappeared. Between 1860 and 1870 much discussion took place as to whether the Royal Infirmary should be rebuilt or whether a new Infirmary should be erected on a different site. The latter alternative was adopted, in great part owing to the advocacy of Professor Syme. The site selected

was that of George Watson's Hospital, between Heriot's Hospital and the Meadows. Here the foundation stone of the present Infirmary buildings was laid on October 13th, 1870. The present Royal Infirmary was opened on October 29th, 1879.

Various changes have taken place in the past two centuries as regards the appointment of physicians and surgeons to the hospital, and the present Infirmary, in the forty-eight years of its existence, has enormously expanded with the introduction of new departments for diseases of the eye, disorders of the ear and throat, radiology, bacteriology, and other special departments and clinics. The present visiting staff numbers sixty-eight, with twenty-six consultants who have served their term of office in the institution. Of the visiting staff, some six attached to special departments are paid as whole-time or part-time officers. With regard to the work of the hospital, in 1926 over 17,000 patients were treated in the wards, while over 56,000 out-patients attended the various departments.

PART OF OLD INFIRMARY, EDINBURGH, CONTAINING LISTER'S WARDS, AND FORMERLY THE HIGH SCHOOL OF EDINBURGH.



During the time that has elapsed since the foundation of the Infirmary nearly two hundred years ago the arrangements for treatment of patients have undergone a gradual evolution. Until the year 1751 all the Fellows of the Royal College of Physicians attended the patients in rotation, but in that year the managers appointed two physicians to the Infirmary at a salary of £30 each. Similarly, all the members of the Incorporation of Surgeons up to 1766 attended the surgical cases in rotation, but in July of that year the managers appointed James Rae, Peter Addis, John Balfour, and Andrew Woods as surgeons to the hospital.

One of the most important developments in the relationship of the Royal Infirmary to the Edinburgh Medical School commenced in the year 1748, when John Rutherford, professor of practice of physic in the University, and grandfather of Sir Walter Scott, obtained permission from the managers to give a course of clinical lectures in the Royal Infirmary. This was perhaps the first course of clinical lectures delivered in this country, and was organized by Rutherford on the model of lectures which he had attended in the hospital at Leyden. Very soon other professors of the medical faculty began to co-operate with Rutherford, and the fame of the clinical teaching at Edinburgh increased, especially in the hands of William Cullen, who commenced to give clinical lectures in 1757 and became professor of practice of physic in 1773. An interesting account is given by Dr. Graves of Dublin of clinical teaching at Edinburgh when he was a student there in 1819. Two clinical clerks, he said, were appointed for the male and female wards, selected by the physician from among the senior pupils.

"Their business was to write an accurate history of the cases, to report the effects of medicines and to record the symptoms which might have occurred since the physician's last visit. At his daily visit the physician stood at the bed of each patient, and having received the necessary information from his clerk, he examined the patient, interrogating him in a loud voice, while the clerk repeated the patient's answers in a tone of voice equally loud. This was done to enable the whole audience to understand what was going on and required an exertion almost stentorian to render this conversation between the physician and his patient audible by the more distant members of the class. Every word was attentively listened to and forthwith registered most faithfully in each student's case-book and afterwards all the observations of the professors, made in their clinical lectures, were taken down with equal care and fidelity."

According to Graves, this method of instruction was indeed very useful, and nothing better could be devised for a beginner. Some forty years later, referring to the year 1853, the following picture of Syme is given by the late Dr. Joseph Bell (said to be the prototype of Mr. Sherlock Holmes):

"His hospital life was on this wise—two clinical lectures a week, operations two days more (perhaps three), a ward visit when he wished to see any special cases; he spent generally about two hours in the hospital. Driving down in his big yellow chariot, with footman, hammercloth, and C-springs, with two big, rather slow and stately white or grey horses, he used to expect his house-surgeon to meet him at the door and move upstairs with him to his little room, where he at once took up his post with his back to the fire and his hands under the flaps of his swallow-tail coat. In this little room he generally held a small *levée* of assistants, old friends, practitioners wanting to arrange a consultation, old pupils home on leave; and before this select class he examined each new and interesting case that could walk in. The new cases had been collected, sifted, and arranged by the dresser in a little room on the stair, irreverently known as 'the trap,' and Mr. Syme then and there made his diagnosis, which to us young ones seemed magical and intuitional, with certainly the minimum of examination or discussion. One was sent off with a promise of a letter to his doctor, another was fixed for to-morrow's lecture or next day's operation. Then, if it was lecture day, a tremendous rush of feet would be heard of the students racing to get the nearest seats in the large operating theatre where the lecture was given. Chairs in the arena were kept for colleagues or distinguished strangers; first row for dressers on duty; operating table in centre; Mr. Syme on a chair on left centre. In his later days it was a fine cushioned chair called the 'chair of clinical surgery.' (In 1854 it was a meek little wooden chair without arms.) House-surgeon a little behind, but nearer the door; instrument clerk with his well stocked table under the big window. He comes in, sits down with a little, a very little, bob of a bow, rubs his trousers legs with both hands open, and signs for the first case. The four dressers on duty, and in aprons, march in (if possible in step), carrying a rude wicker basket, in which, covered by a rough red blanket, the patient peers up at the great amphitheatre crammed with faces. A brief description, possibly the case had been described at a former lecture, and then the little, neat, round-shouldered, dapper man takes his knife and begins; and the merest tyro sees at once a master of his craft at work—no show, little elegance, but absolute certainty, ease and determination; rarely a word to an assistant—they should know their business if the unexpected happens; his plans may change in a moment, but probably only the house-surgeon finds it out; the patient is sent off, still anaesthetized, and then comes a brief commentary, short, sharp and decisive, worth taking verbatim if you can manage it, yet he has no notes, a very little veiled voice, and no eloquence."

ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH.

Into this atmosphere Joseph Lister stepped in 1853 and took up the position of house-surgeon to Syme in 1854. Returning from his period of office as professor of surgery

in the University of Glasgow, he succeeded Syme as professor of clinical surgery in 1869. Lister's wards were situated in that part of the Infirmary which had formerly been the High School of Edinburgh, and which still stands as the Engineering Department of the University at the foot of Infirmary Street.

The Royal Hospital for Sick Children.

The first hospital for sick children in this country, that of Great Ormond Street in London, was opened in February, 1852. For some time before and after 1840 Dr. William Campbell, lecturer on midwifery in Argyle Square, Edinburgh, gave a full course of lectures on the diseases of children, and these lectures were the first of the kind delivered in Edinburgh. Appeals began to be made about the year 1856 in the columns of the *Edinburgh Medical Journal* as to the expediency of founding a hospital for the diseases of children in Edinburgh, and later, about 1859, an agitation was made for the same purpose in the *Scotsman*, the *Witness*, and other papers. Premises were secured at No. 7, Lauriston Lane, and on February 15th, 1860, a hospital with twenty-four cots was opened. In May, 1861, the directors purchased Meadowside House *at the foot of Lauriston Lane, with ground adjoining* to the extent of one acre, and here a hospital was established for forty patients, including a separate fever ward. This building was formally opened in May, 1864, and a new surgical department was added in 1889. Here over 600 patients were treated annually. For a short time after 1890 the hospital was removed to a building formerly used as a hydropathic at Morningside, and subsequently, when the present building was completed in Sciennes Road, the hospital moved back to the central portion of the town. The hospital is a handsome building constructed of red sandstone, with two ward pavilions, three stories in height, and a central administrative block. Adjoining the hospital is a large out-patient department. There is also a convalescent home situated at Muirfield, Gullane, in which chronic cases and cases requiring a prolonged convalescence are treated by the seaside. During 1925, 2,968 cases were treated in the wards of the hospital and 7,459 out-patients, involving 28,242 attendances, at the out-patient department.

Royal Edinburgh Asylum.

The Royal Edinburgh Asylum for the Insane was founded by a charter in May, 1807, and the foundation stone of the institution was laid in June, 1809, by the Lord Provost of Edinburgh. The founding of this institution was largely the outcome of a suggestion by Dr. Andrew Duncan, who had been greatly impressed by the miserable death of Robert Ferguson, the poet, while insane in the common workhouse in 1774. When Duncan became professor of institutes of medicine, in 1792, he again brought up the matter, and in addition to the Royal Charter obtained a Government grant of £2,000 for the erection of this lunatic asylum at Morningside, Edinburgh, on modern, humane lines. This was the original East House, which, with the growth of the city, has now disappeared. The West House was added later, and in June, 1890, Craig House, on the slopes of Craiglockhart Hill, was obtained, and further asylum buildings added, which were opened in October, 1894. In 1917 an important further step in dealing with cases of mental disorder was taken by the managers of the Royal Asylum, who instituted five nursing homes for mental cases in Edinburgh, so that these could be treated without the objectionable feature of certification. A sixth home, known as Jordanburn Hospital, and intended for persons of the poorer classes, is at present in process of erection. The average annual number of patients under treatment in the institution is 850, and the managers have recently applied to Parliament for an order to change the name of the corporation and of the institution from that of the Royal Edinburgh Asylum to "The Royal Edinburgh Hospital."

Royal Maternity and Simpson Memorial Hospital.

In 1756, when Dr. Young was appointed professor of midwifery at Edinburgh University, a ward in the attic story of the Royal Infirmary, by permission of the managers, but at Dr. Young's expense, was fitted up for four lying-in women, or as many more as Dr. Young could accommodate, each exceeding the number four paying 6d. a day to the house. With the view of obtaining further opportunities for practical instruction the professor also gave notice that patients should be delivered at their own house free of expense and, if necessary, supplied with proper medicines. Dr. Alexander Hamilton succeeded to the chair in 1780 and carried on the same arrangements for about ten years. He was now allowed six beds in the attic ward of the Royal Infirmary, but he found this was altogether inadequate for the purpose of training nurses as well as teaching students. In 1791, therefore, he made proposals for the establishment of a lying-in hospital, and in the beginning of November, 1793, a proper building was purchased and a hospital was opened with the title of the Edinburgh General Lying-in-Hospital. Professor Alexander Hamilton was himself the ordinary physician to the hospital, and Dr. C. Stuart held the position of extraordinary physician. This house served as a maternity hospital for nearly fifty years and was situated in Park Place. Attendance on this institution was afterwards carried on by James Hamilton, the son and successor of the first Hamilton, *during his long incumbency of the chair of* midwifery, lasting forty years. Here the younger Hamilton was assisted by Dr. John Moir, who lived in the neighbourhood, and latterly took over most of the attendance on the hospital from the professor. After 1843, the house in Park Place being sold, the Lying-in Hospital went through a series of migrations, being transferred successively to a house at No. 2, John Street, where it became known as the Royal Maternity Hospital; three years later to Milton House in the Canongate; in 1852 to Minto House, and in 1856 to Chapel House, where it remained sixteen years. From 1872 to 1874 it occupied George Watson's Hospital buildings, acquired by the Royal Infirmary, which, however, was not yet able to use the building for wards. In 1874 it was transferred to 18, St. John Street, until a sum of money collected to perpetuate the memory of Sir James Y. Simpson became available, and in May, 1879, the new hospital in its present situation was opened for the reception of patients. Here the hospital has continued to grow both in usefulness and extent until further extension has become impossible. It has been affiliated with the five dispensaries of the city and has established a department in Leith. One of the most modern developments of the hospital was the ante-natal department established by the late Dr. J. W. Ballantyne, of which an account was given in the British Medical Journal of March 20th, 1926 (p. 539). In taking this step the hospital enjoys the distinction of having been the first hospital in the United Kingdom to initiate the movement for ante-natal supervision of expectant mothers. As it has become urgently necessary to rebuild the hospital, and as its present site is incapable of expansion, arrangements have been made between the Infirmary and the directors of the Royal Simpson Memorial Hospital that the latter should be amalgamated with the Royal Infirmary, and it will in course of time be rebuilt on a site in the immediate neighbourhood of the present Royal Infirmary buildings. During the year 1925 the hospital treated 1,854 indoor patients and 531 outdoor patients, while the Leith branch attended 549 women, making a total of 2,934 patients delivered in or in connexion with the hospital, a number which covers 35.5 per cent. of the total births in Edinburgh. The ante-natal clinic was attended by 1,297 patients with a total of 4,121 visits.

Leith Hospital.

Leith Hospital is an institution which has gradually developed to its present size of a hospital containing nearly 100 beds. The Edinburgh and Leith Humane Society was founded in 1788, a dispensary was added in 1815, with a casualty hospital in 1837, and these institutions were combined as Leith Hospital in 1848 and incorporated in 1907. The hospital occupies a central position in the town of Leith, which now forms a portion of the city of Edinburgh. The most recent addition to the hospital was a ward for children containing thirty-six cots, which was completed in 1926 and opened as a war memorial to commemorate the men from Leith who fell in the great war.

Deaconess Hospital.

The Deaconess Hospital was founded by the Church of Scotland as a memorial to Lady Grisell Baillie, one of the initiators of the modern Deaconess movement. The hospital was founded in 1894 and contains some fifty beds, including wards for men and women, a gynaecological ward, and a children's ward. The number of patients treated in hospital during 1926 was 716, while at the out-patient department 5,960 patients were treated, with total attendances of 26,804. The hospital is situated in the densely populated district of the Pleasance, where its services are particularly valuable to the poor of the locality.

Chalmers Hospital.

In the year 1836 George Chalmers, plumber in Edinburgh, bequeathed the residue of his estate, amounting to £30,692, to the Dean and Faculty of Advocates for the purpose of founding a new hospital for the sick and hurt. After allowing the fund to accumulate for some years the trustees erected the present hospital in Lauriston Place, which was opened for patients in the year 1864. An addition to the hospital was made in 1898 to commemorate the Diamond Jubilee of Queen Victoria, and more recently alterations have been made to improve the surgical department of the hospital. The hospital contains almost fifty beds, equally divided between medical and surgical cases, with gynaecological and aural departments. The total number of patients treated in hospital during the year 1926 was 925. In addition to these, 3,571 persons received treatment at the out-patient department. Since an early period in its career this hospital adopted a principle which is at the present day considered to be an ideal arrangement for general hospitals, in the provision of private wards as well as free beds. The charge for maintenance in the private wards is at present fixed at 10s. 6d. per diem.

Royal Edinburgh Hospital for Incurables.

This hospital occupies a somewhat unique position among the hospitals of Scotland. Attention was drawn half a century ago to the urgent necessity for the provision of hospital accommodation for persons suffering from incurable diseases. A public meeting was held in Edinburgh in December, 1874, as a result of which the Edinburgh Association for Incurables was founded. The hospital, which was opened in 1875, originally provided twenty-two beds, intended for the reception of incurable cases, and for the purpose of affording the medical profession an opportunity of studying more carefully that class of disease which had hitherto been considered incurable. At the present time the hospital maintains two institutions—the Longmore Hospital, situated at Salisbury Place, Edinburgh, with accommodation for 160 beds, and Liberton Hospital, opened in 1906, with fifty beds, at Liberton, on the southern outskirts of the city, where cases of advanced tuberculosis especially are treated. A considerable proportion of the tuberculosis cases are of surgical tuberculosis in children, and with such cases there is often an encouraging number of successful cures. The hospital also possesses funds for affording outdoor benefit to patients who have recovered sufficiently to be discharged. The number of patients treated in the two hospitals during the year ending March, 1925, was 329, and the total number of patients treated during the fifty years of the hospital's existence up to that date was 5,933.

Royal Victoria Hospital for Tuberculosis.

The Victoria Dispensary for consumption and diseases of the chest was opened in November, 1887, at 13, Bank Street, under the superintendence of Dr. (now Sir Robert) Philip. As the result of growing activity and usefulness, the dispensary was removed in 1891 to 26, Lauriston Place. By this time about sixty cases were seen three times a week. During 1892 the important step of visiting patients in their own homes was undertaken, so as to trace other infected cases among those who had come into intimate contact with the patients. In 1894 Craigleith House, on the north side of the town, was taken as a hospital for tuberculosis and named the Royal Victoria Hospital. Here various pavilions were added in 1903 and at subsequent dates. The increasing activity of the dispensary necessitated its removal in the year 1911 to a large building which had become available in Spittal Street. This removal was made the occasion of a semi-jubilee celebration. At this time 2,042 visits to tuberculous families were paid annually by the doctors attached to the institution, and 5,273 visits by a staff of nurses. In 1910 Polton Farm Colony, situated in the country to the south of Edinburgh, was established, where on a farm some twenty persons suffering from chronic tuberculosis could obtain useful employment suited to their physical abilities. The organization was taken over by the Corporation of Edinburgh in 1914, the Royal Victoria Hospital being now provided with some 100 beds. The Tuberculosis Trust has still continued its activities, and in addition to the organization as managed by the Edinburgh Corporation, the Trust established the Sanatorium Colony of Southfield, near Liberton, in 1919, where cases of tuberculosis in any of its forms are treated and about forty patients are received. As another aspect of antituberculosis work, the Trust in 1923 leased the farm of Gracemount in the same neighbourhood, and established a model dairy farm with a herd of tuberculin-tested cows for the supply of certified milk.

Edinburgh Hospital for Women and Children, and the Hospice.

The Edinburgh Hospital for Women and Children, with a female medical and surgical staff, was founded in 1879 in Whitehouse Loan. The hospital increased gradually in size until now it contains some fifty beds. The Hospice was inaugurated in 1904 at 219, High Street, with ten beds, and maintained a separate existence until 1910. In that year the two institutions were amalgamated under one committee. In July, 1925, this committee reconstituted the Hospice and transferred it to Spring Gardens, overlooking the King's Park, as the Elsie Inglis Memorial Maternity Hospital. This hospital contains forty-five beds, and is shortly to be extended to sixty beds. It is reserved for the treatment of obstetric cases. These two hospitals have a certain number of free beds for persons unable to pay anything, but whenever possible patients are expected to pay from 25s. to 3 guineas weekly, the latter charge being the cost of a private room. The number of cases treated in the Bruntsfield Hospital during 1926 was 667, while the number treated at the Elsie Inglis Memorial Hospital was 670, with 213 cases in their own homes in the surrounding district.

THE DISPENSARIES.

Edinburgh was one of the first cities to institute dispensaries for the medical treatment of the sick poor.

The *Royal Public Dispensary* was the first of these, being founded in the year 1776 and incorporated by Royal Charter in 1818. It has thus completed over 150 years of existence. Its institution was largely due to the suggestion and effort of Dr. Andrew Duncan, who was also responsible for the initiation of several other of the Edinburgh medical institutions. The dispensary combines the double purpose of affording attendance to the sick poor and of giving instruction and an opportunity for practice to senior medical students. The medical officers attend in rotation on different days of the week, and each has a group of students with whom he sees those patients attending for advice, and to whom he apportions the patients requiring visits at their own homes. The patients receive gratis the medicine prescribed for them. This system of dispensary teaching has been an important feature of the practical instruction given by the Edinburgh Medical School during more than a century.

New Town Dispensary.—As the town grew and the poorer part of the population removed from its eastern end, new dispensaries were established. The first of these was the New Town Dispensary in Thistle Street, which was instituted in 1815. Here some 10,000 of the sick poor receive attendance by the medical staff and by students each year, as well as such medicines as may be necessary.

Livingstone Memorial Dispensary.—This dispensary was founded by Dr. Handyside in 1858, with the double object of providing medical attendance for the sick poor of the Cowgate district and a training school for medical missionary students. The dispensary in 1861 became the Edinburgh Medical Missionary Society Training Institution, and here various agencies, medical, social, and religious, are centred. The society also supports hospitals in Nazareth and Damascus, and trains students for work in these and various other mission fields. In addition the society maintains a convalescent home at Duddingston on the outskirts of Edinburgh, and deals with approximately 10,000 sick persons annually.

Western Dispensary.—This institution was founded in 1870 for attendance on the poor in the western part of the city.

Provident Dispensary.—This dispensary, established in 1878, was founded to provide the poor with medical attendance without making them feel entirely dependent on charity; it is supported by subscriptions, donations, and small payments made by patients for medicines. It occupies a position in Nicolson Square, close to the University, and is attended by students similarly to other dispensaries.

Dispensary for Women and Children.—The Dispensary for Women and Children at 21, Torphicen Street, is managed in connexion with the Bruntsfield Hospital for Women and Children and the Elsie Inglis Memorial Maternity Hospital. In addition to this dispensary there is a Steel-house Dispensary in the grounds of the Elsie Inglis Memorial Hospital at Spring Gardens, intended for maternity and child welfare work, and a branch dispensary at 29, Windsor Street.

British Medical Journal.

SATURDAY, MARCH 26TH, 1927.

THE MENTAL DEFICIENCY BILL.

THE Mental Deficiency Bill was read a second time in the House of Commons on Friday of last week without a division. The bill is almost identical with the Government measure which at the end of last session was withdrawn for lack of time owing to somewhat unexpected opposition encountered in the concluding stages. The present bill is a private member's measure, and is presented by Mr. Crompton Wood, supported by Sir Douglas Newton, Sir Leslie Scott, Mr. Rhys Davies, Mr. Cadogan, Dr. Fremantle, and others. The memorandum explanatory of the bill was published in this JOURNAL last week (p. 549), and the admirable and interesting debate on the second reading is reported this week on page 602. As the bill has secured a second reading so early in the parliamentary session, as it received support so emphatic from the Ministry of Health, and as it was definitely opposed by one Socialist member only on grounds of pure individualism, it is to be presumed that its further progress will be facilitated by the Government, and that it will become an Act of Parliament before the session closes. In view, however, of what happened to its immediate predecessor it would be well for those who regard this consummation as of great importance —and the medical profession is included among these —*not yet to relax their efforts, but to urge members of* Parliament whom they can influence to give the bill active and continued support.

The bill proposes to amend previous enactments relating to mental defectives in three main ways. The first of these is by a change of definition. Hitherto there has been no legal definition of mental defectiveness; there have been merely definitions of certain classes of mentally defective persons. In the Act of 1913 each of these definitions included the statement that the mental defect must have existed "from birth or from an early age." Experience has shown the necessity for getting rid of these words on two grounds. On the one hand, there have been a considerable number of cases in which, though the mental deficiency was undoubted, and though to an expert investigator it was evident that the condition was congenital, it was impossible to produce actual evidence that the condition existed in the earliest years of life, since nothing was known of those years. In these circumstances magistrates have felt themselves unable to take action, and doctors have hesitated to certify. On the other hand, there are certain causes arising at a somewhat later age, such as the occurrence of encephalitis lethargica or of a severe head injury, which may produce an arrest of mental development, making it highly desirable that administrative or educational action should be taken on the same lines as though the condition were congenital. The definition now proposed will get rid of both of these difficulties. The classes of mentally defective persons (idiots, imbeciles, feeble-minded persons, and moral defectives) are differentiated as hitherto; but it is provided that "mental defectiveness" shall mean "a condition of arrested or incomplete development of mind existing before the age of 18 years, whether arising from inherent causes or induced by disease or injury." The introduction of a precise age limit into the definition is not scientific, and the medical profession would probably prefer a phrase of less rigid meaning, but its practical convenience for magistrates and administrators, and the fact that it will curiously satisfy a few parliamentary objectors, are held to outweigh any more theoretical disadvantages. A warning should be given, however, against any attempt to raise the prescribed age in Committee. Even if a few cases of real mental defectiveness should escape, it is essential not to include cases of unsoundness of mind which are of a different character, and which should be dealt with under the lunacy laws.

The second principal way in which the bill proposes to amend previous Acts is by a slight but important extension of the categories of defective persons who may be dealt with. In addition to defectives who are habitual drunkards, or who have given birth to an illegitimate child while in receipt of Poor Law relief, or who have been found guilty of a criminal offence or sent to a reformatory or industrial school, a defective can, under the present law, receive the protection of the Act of 1913 only if he be "found neglected, abandoned, or without visible means of support, or cruelly treated." Experience has shown that these restrictions tell very hardly on, for example, the poor mother of a mentally defective child (under 7 or over 16 years of age, and not notified by an education authority) for whom she is anxious to secure the treatment and training that can be obtained only in a properly equipped and staffed institution. Such a mother who has been giving her child all the devoted attention possible in her circumstances naturally resents having to plead "neglect," even though, in one sense, the child is neglected in that he is not receiving the care, training, and attention for which his or her condition calls. It is now proposed to add to the subsection above quoted the words, "or not under proper care or control." This addition will meet a class of case in which difficulty has been experienced.

The third main amendment proposed by the bill is to extend the methods by which certain classes of mentally defective persons may be dealt with. There are three such methods: (1) sending to an institution; (2) placing under guardianship; (3) supervision. At present children who have been educated as far as possible in a special school or class may, on or before attaining the age of 16 years, be notified by the education authority to the authority under the Mental Deficiency Act as needing guardianship or institutional care, but not as requiring supervision merely. There is a considerable proportion of higher grade defectives who can, with a varying amount of skilled supervision, safely be left in the care of their parents or employers and who do not need any more restrictive procedure. For such cases no legal supervision is now provided, and often, through its neglect, they become socially as well as mentally defective. The new bill proposes to remedy this omission.

All these alterations of the law are obviously reasonable in themselves and have been shown by experience to be really necessary. A large amount of thought, time, and care is being given by many persons in the most devoted and kindly way to supplying the needs of this peculiarly unfortunate class of mental defectives. The defectives themselves are found to be not only more useful and more largely self-supporting, but also much happier when they feel themselves protected in one or other of the ways that the law provides; and there need be no fear, even on the part of the most

suspicious, that as a result of the proposed amendments there will be any tendency to deprive any persons of the liberty they should enjoy.

CANCER STATISTICS.

STATISTICS are made use of almost universally as an adjunct to medical investigation and research by experiment; there is no question of their utility in this connexion. When, however, they are made to replace experiment as a mode of investigation they are apt to acquire discredit if the principles governing their use are not strictly observed. In the solution of simple problems, such as the death rate per thousand of the total population, there is not much danger of going astray; but where complex problems are concerned, such as the influence of heredity in cancer, the alleged increase in its occurrence in recent years, and the influence of civilization as an etiological factor, more is often demanded of statistics than they can reasonably be expected to perform. It is not always realized that the conditions in a statistical problem need to be as carefully thought out as in an experimental problem.

The degree of reliance to be placed on statistics as at present employed forms the subject of an interesting paper in the *Journal of the American Medical Association* by Dr. Gideon Wells, entitled "Cancer statistics as they appear to a pathologist." He shows, in the first place, that statistics often give different answers to a plain question—for example, What is the commonest site of carcinoma in women? The statistics of the Middlesex Hospital give the breast as the commonest site; the Huntingdon Hospital, Boston, gives the skin; and the author's autopsy records from the Cook County Hospital give the stomach. It is by no means infrequent to find statistics applied in this manner, the data employed consisting neither of totals nor of fair samples of totals, and the deductions being made with a fine disregard of logic. Such misapplications as these are to be referred to an ignorance of statistical science rather than to any defect in the science itself. The ordinary methods of applying the general vital statistics to the solution of cancer problems are unreliable. Here the question of diagnosis comes into prominence, and this, added to the fact that the data employed cannot possibly be homogeneous, is a fruitful source of false deductions. In many cases no *post-mortem* examination has been made, and where this is so a considerable margin of error needs to be allowed for. Dr. Wells cites figures which give some idea of the possible extent of error that may arise from this cause. In his own hospital, out of 545 malignant growths, 367 were correctly and 178 wrongly diagnosed; Bashford's statistics from a number of London hospitals showed an error amounting to 112 in 396 cases; Reichelmann reported 156 errors in 711 cases in a Berlin hospital, and similar results have been reported from Budapest, Poland, Jena, and elsewhere. In addition many cases were diagnosed as cancer where it did not exist. Although Dr. Wells goes fully into the matter, it hardly seems necessary to inquire whether there is likely to be any considerable error in connexion with statistics based on death certificates instead of *post-mortem* examinations; if these things are done in the green tree, what shall be done in the dry?

Turning to the influence of heredity in cancer, the author states that existing statistics are worthless. The information obtainable from patients varies greatly with the circumstances. If a patient seeks advice for what he knows to be cancer, it is probable that he will have made full inquiries as to the occurrence of the disease in his family; whereas if he is suffering from some other disease, such as peritonitis, the family history will not have interested him. Another inherent source of error is the fact that a certain proportion of the patients will develop cancer at some later date, and yet they are used as non-cancer material. Further, if we attempt to work out the heredity of cancer with statistical material, using Mendelian principles, we find that this is impossible, for a single error of diagnosis might invalidate an entire family record, and there are probably no existing families with complete necropsy records of all deceased members for any considerable periods.

On the whole, statistics agree in indicating that cancer has been increasing in frequency in recent years, but the significance of the fact is not yet agreed on. As the average duration of life increases and infant mortality decreases, and as diseases such as typhoid fever and diphtheria become eliminated, it would seem safe to assume that the number of candidates for cancer must increase. A high crude cancer death rate may therefore be evidence of a good state of public health. Again, with an increasing accuracy of diagnosis many more cases of internal cancer should find their way into the records than heretofore. Reasons such as these may seem sufficient to account for an increased frequency of the disease. Yet the problem is not so simple as at first appears. No tendency to increased frequency has been reported by observers who have selected for consideration only the external cancers, which are unlikely to be incorrectly diagnosed. Willcox found that the cancer increase in Frankfort for the period 1860-1913 was limited to inaccessible growths, and similar reports come from Stuttgart, Berlin, Hamburg, and Great Britain.

Dr. Wells is no less sceptical of the value of statistics in reference to the influence of civilization and the supposed increase of cancer in primitive peoples when they come in contact with modern civilization; and he sums up his reflections on the whole subject in the following terms: "After thinking about what the figures may mean, and what they really mean, and what others think they mean, I find myself unable to accept anything about cancer as finally established by statistics." One conclusion to be drawn from his investigations is that there must be a sad ignorance of the science of statistics and of its proper mode of application.

LISTER CENTENARY IN LONDON

IN our issue of March 5th (p. 437) we announced the arrangements made for celebrating in London the centenary of the birth of Lord Lister, which falls on Tuesday, April 5th next. At the reception of delegates by the Prime Minister, which will take place at 11.30 a.m. that day in the Great Hall of the British Medical Association House, there will be a considerable number of seats available for members of the medical profession and for the general public. Members desiring tickets for themselves and friends are requested to make immediate application by letter to the Financial Secretary, B.M.A. House, Tavistock Square, W.C.1. Tickets are available also for reserved seats at the ceremony in Westminster Abbey on the morning of April 6th. The arrangements made for the celebrations by the London committee are summarized in a time-table printed in the SUPPLEMENT at page 104, where information about academic dress will be found.

FRENCH EXPERIMENTAL WORK ON TUBERCULOSIS.

IT would appear that more experimental work in tuberculosis is being done in France than in England, and the results of several such researches have been reported to recent meetings of the Académie de Médecine of Paris. Perhaps the apparent difference between the two countries is due to tuberculosis being a more serious disease in France; or perhaps the enthusiasm of Calmette stimulates other workers. Dr. Vaudremer recently presented a report on some further researches undertaken by himself and Drs. Puthomme and Paulin on the development of the tubercle bacillus. The experiments consisted in cultivating on gelatin tubercle bacilli which had been submitted previously to the action of substances elaborated by the *Aspergillus fumigatus*. They claim to have proved as long ago as 1910 that the growth of this fungus will destroy the greater part of a culture of tubercle bacilli in glycerinated broth, and with it the tuberculin. The recent experiments showed that in cultures of tubercle bacilli exposed for a few days to the products of the growth of the aspergillus there appeared, among masses of acid-resisting organisms, a number of granules, and of bacilli with a terminal granule, which had lost the resistance to acid and were colourable by methylene blue. The granules resembled in appearance Gram-staining meningococci. Ultimately the typical bacilli in the culture completely disappeared, and were replaced by zoogloeal masses of cyanophile granules. Shortly after the appearance of these masses the culture medium became cloudy; and at this point it was possible to make fresh cultures of the granules on a gelatin medium. With successive cultures the granules assumed the form of a cyanophile, granuliferous matting similar to that described by Bezançon and Philibert. The cultures on gelatin appeared to die quickly; but if kept for some months resuscitation occurred, and amidst cyanophile granules and acid-resisting granules typical bacilli were found. In the same preparation it was possible to follow the passage from the ordinary granule to the classic bacillus of Koch. None of the elements grown in aspergillus fluid or on gelatin produced tuberculosis in guinea-pigs. To render them virulent it was necessary to grow them in a medium of animal origin, such as glycerinated ox serum. They would then kill guinea-pigs in eight days. If, however, the gelatin cultures were killed by heat, they conferred, when subcutaneously injected into guinea-pigs, a marked resistance to tuberculosis, lasting at least fifteen months. As a result of these experiments tubercle cultures simply modified by aspergillus fluids were at first used therapeutically on patients at the surgical clinic of the Salpêtrière under Professor Gosset. The treatment was applied in 128 cases of surgical tuberculosis, and 85 were followed up. The best results were obtained in osteitis of small bones, in adenitis, epididymitis, and peritonitis. The treatment was less effective in hip disease and in aged persons. Subsequently cultures on gelatin from the aspergillus fluid were used, and 260 patients were treated by this method, which gave better results, over 75 per cent. being cured, as compared with 48 per cent. under the first method.

HISTORY OF MEDICINE.

THE Section of the History of Medicine of the Royal Society of Medicine held its last ordinary meeting of the session on March 16th, when four communications on widely different subjects were made. The first was a paper by Sir D'Arcy Power on the place of Tudor surgeons in English literature, which Dr. Kenneth Hay read for him in his absence. This showed by examples how faithfully the English surgical writers of the sixteenth century reflected the changing character of the nation during the renascence i[illegible] of printing into this country. The love of nature and of the open air characteristic of the period revealed itself in the opening passages of Thomas Gale's *Institution of a Surgeon*, and in extracts from William Bullen's *Dialogue Against the Fever Pestilence*. Another good example of contemporary literary style was that of William Clowes, writing on the subject of syphilis. That Master Clowes could speak his mind very plainly when the occasion called for it was shown in a paragraph of invective against the deplorable state into which English surgery had fallen in his day. This generation of surgeons—Hall, Gale, Clowes, and Read—tried an experiment which began and ended with them, and happily failed; they essayed to write in verse, and the lines quoted by Sir D'Arcy Power proclaimed them pretty bad versifiers. But the prose passages went far to substantiate his claim that the Elizabethan surgeons had a definite place in English literature at a time when our written language was being moulded ready for the hand of Shakespeare and the translators of the Authorized Version. Dr. Charles Singer next introduced to the Section a record, compiled with great pains by Professor E. Morpurgo of Padua, of the many English physicians who studied in the Collegio Veneto Artista of the University of Padua between 1617 and 1771. Greater than any of these names, however, is that of William Harvey, who received his doctorate at Padua in 1602; the illuminated diploma is one of the treasures of the Royal College of Physicians of London. Dr. Singer then showed some photographs of a recently discovered example of the Egyptian god Bes, giving in detail his reasons for thinking that the original of this grotesque image suffered from spina bifida. Lastly, Dr. Herbert Spencer showed the very rare book, Wolveridge's *Speculum Matricis*, printed in 1671, together with two manuscript copies in the society's library—one of them beautifully written and illustrated with loving care. Dr. Spencer traced this book to a much earlier work, and told how Wolveridge's manual for midwives was itself plagiarized later under another name.

WILD RODENTS AND PLAGUE.

AMONG the communications submitted to the Standing Committee of the Office International d'Hygiène Publique at its recent meeting in Paris is one which treats of the increasing activities of wild rodents as agents in the transmission of plague. There are places in Asia, Africa, and America where rat plague, originally brought to the coast on shipboard, has made its way inland, infected indigenous wild rodents, and so established itself as a settled enzoötic in tracts previously immune. In each locality a few species only are the constant reservoirs of infection. Among them are the marmot, *Arctomys bobac*, in the north-east of Asia, the gerbille, *Tateroma lobengulae*, in South Africa, the sousliks in South-West Russia, and the *ground squirrels* in California. As a class they are trapped or shot with a view to the protection of crops or for their own intrinsic value, and those who pick up or handle their carcasses may contract plague from the fleas. Field-mice, such as *Rattus coucha* and *Arvicanthis pumilio*, serve as intermediary channels of infection, bringing the disease with them from the open country into the dwellings of man. Among the fleas implicated are *Ceratophyllus silanticri* and *Neopsylla setosa*. In these areas the common rat, for once, seems comparatively blameless. It is true that he started the enzoötic at first, but having done this he does not himself, under these conditions, pass plague on to man. Plague in wild rodents shows a tendency to visceral, and especially pulmonary, involvement. It is remarked that in hibernating rodents infection may remain localized during hibernation, awakening to activity at the close of the winter sleep. Plague in man contracted from [illegible] rather apt to assume the pneumonic form;

such cases may or may not be preceded by cases of the bubonic type. The attempt has been made to extinguish enzoötic plague by exterminating the peccant rodents. This has proved a formidable and costly task. Short of wholesale destruction, however, some good may be done by local repression. Clear zones are established round inhabited places as buffers against the wild. Rodents are kept down in these zones by the use of poison bait, poison gas, and explosives, or by turning to account their natural enemies, such as carnivores, birds, and snakes. With regard to marmots, there is the special point that marmot-catching is a lucrative business which those engaged in it are unwilling to abandon. It is recommended that it should be scheduled as a dangerous trade, and governed by regulations for the protection of workers.

NATIONAL HEALTH INSURANCE STATISTICS.

THE statistical review of national health insurance given by Sir Alfred Watson, the Government Actuary, to the Royal Statistical Society, and reported in the SUPPLEMENT of last week (p. 94), shows the vast extent and some of the many complications of the scheme of insurance. His figures are not only interesting in themselves, but have an important bearing on all proposals for the extension of the medical services. The accumulated funds now reach a total of £120,000,000, a sum which, as the Royal Commission recommended and as we have previously noted, should be sufficient for those extensions of medical, maternity, and laboratory services which are urgently required. The total number of insured persons is given at about 15,600,000. It is interesting to note that between 1919 and 1923 some 5,263,000 persons entered insurance, that the numbers of men and women were almost equal, and that 60 per cent. of them came in at the age of 16 years. With entrants in such numbers compulsorily secured, the scheme can scarcely be held to require any overloaded reserve fund. During the same period some 3,000,000 women left insurance, more than 800,000 on marriage, and the remainder apparently mainly because their resort to industrial employment was only temporary. Of the 1,800,000 men who went out, it is concluded that the great majority of those over 35 years of age did so by reason of their taking up forms of occupation other than employment. It would, however, be valuable to be told, if possible, how many of these, both men and women, were clerical workers who left insurance by reason of their salary rising above £250 a year. Such information has never, we believe, been forthcoming. The statistics of sickness benefit relate, first, to the numbers claiming such benefit, and secondly, to the average duration of incapacity. Under the former heading experience among men and among unmarried women is eminently satisfactory, and that among married women only less so. A marked improvement in the health of the community seems to be indicated, the "rate of sickness" being on the average 20 per cent. less than the experience of the Manchester Unity of Oddfellows in the years 1895-97, on which, it will be remembered, the actuarial calculations for the national scheme were based. Figures with regard to the duration of incapacity, more particularly among women, are not so good. This duration in the case of married women claimants averaged eight and three-quarter weeks. This is a very high figure, and seems to call for some explanation. One conclusion which it seems possible to draw from the combined figures is that the opportunity to work is one of the best preventives of incapacity to do so. Among women the sum drawn in the war years 1916-17 was less than two-thirds that drawn in 1913-14, and since the war these claims have again risen, till they are now approaching the level of the earlier period. Disablement benefit has, of course, been an increasing quantity as the insurance scheme has grown to maturity. It is estimated that there are now about 200,000 persons permanently disabled and drawing benefit from approved societies. Altogether, it seems to be established that the effects on national health are beneficial, that the financial position is satisfactory, and that there is every reason why those improvements of the service which have been advocated by the medical profession and others, and endorsed by the Royal Commission, should be proceeded with without undue delay. Some further discussion of Sir Alfred Watson's paper, by a well informed correspondent, will be found at page 589.

HOSPITAL DIFFICULTIES IN CHINA.

FAILURE on the part of the Southern Government of China to appreciate the essential lines on which modern hospitals must be conducted has compelled the board of directors of the J. G. Kerr Hospital for the Insane in Canton to close that institution. We referred on February 26th (p. 392) to the dispute between this hospital and the local labour union, and mentioned that the Cantonese Government had expressed a certain amount of sympathy with the hospital. It has now, however, issued a series of regulations for the administration of all hospitals in China, whether Chinese or Western, public or private; the terms of these, though less absurd than those suggested by the labour union, are of such a nature as to render continuance of hospital work impossible. The fact that many of these hospitals are almost wholly supported by the charity of subscribers outside China is ungratefully ignored, and the hospitals are henceforth to be compelled to accept the additional liability of treating all their sick employees until well without deduction from wages. In the event of the death of an employee who has served for more than a year, the hospital must pay the relatives the equivalent of six months' wages; hospitals for contagious diseases are similarly liable for twelve months' wages, while if the worker has been employed for more than six years the grant must be larger: "the amount to be discussed at the time," though by whom is not revealed. Hospitals are permitted to engage their employees as they please, but must then compel them to join the local labour union. If the dismissal of any employee causes trouble among the workers the Government will establish a court of arbitration, during whose deliberations no employee of the hospital may be dismissed for any reason, however protracted the proceedings of the court may be. Picketing is forbidden, and more or less suitable arrangements for public holidays are defined, but, since it is stated that these regulations can be "amended" at any time by the officials, any element of security would appear to be lacking. Dr. James Maxwell, who is secretary of the China Medical Association, has sent us a reprint of these regulations, which were published in the *South China Morning Post*. He states that the executive committee of the China Medical Association is advising its members to close their hospitals where these regulations are to be put into force. He adds that joint action is likely to be taken by the Chinese National Association and the China Medical Association to impress on the Southern Government the gravity of the situation thus created, with a view to obtaining the withdrawal of these regulations.

THALLIUM.

AT the meeting of the Section of Dermatology of the Royal Society of Medicine on March 17th Professor W. E. Dixon gave some results of experiments on the pharmacology of thallium carried out under his charge by Dr. J. H. Wadia. Thallium exerts the remarkable action of causing a loss of hair and general alopecia in all animals. On the other hand, if skin areas of animals are shaved, thallium induces a rapid growth of hair in these parts compared with control animals. Histologically the interruption in the normal

growth of the hair in animals treated with thallium appears to depend on a failure of the normal process of transition from the large polygonal epithelial cells of the hair bulb to the horny scales of the hair. Thallium rubbed into the skin with oil or alcohol is readily absorbed, but exerts no action on the skin until after absorption; it has no local action. It exerts no action of moment on the vessels of the skin, and although it can be found in almost every tissue of the body after absorption, the skin is an exception; so that its action, unlike that of arsenic, cannot be a local action on the skin. One other most remarkable feature of thallium is its effect on the autonomic nervous system. The whole autonomic system becomes more sensitive, so that electrical stimulation of nerves produces an exaggerated response. This is most marked on the sympathetic portion of the autonomic system. Professor Dixon suggested that this was the explanation of the increased growth of hair or alopecia which supervened with thallium therapy. He compared the action with ordinary alopecia, and gave some reasons for believing that such alopecia also was due to some abnormal functioning of the autonomic system. In view of the action of thallium on the suprarenal gland, which is so closely associated with the sympathetic system, he suggested that suprarenal therapy might be worth trying by dermatologists in certain cases of alopecia.

REST PAUSES IN HEAVY WORK.

THE Industrial Fatigue Research Board is accumulating valuable information on the occurrence and effect of rest pauses in various forms of work. Until recently the investigations were concerned for the most part with light repetitive occupations; the latest report to the Board by Dr. H. M. Vernon and Mr. T. Bedford, assisted by Mr. C. G. Warner, deals with "Rest pauses in heavy and moderately heavy industrial work" (H.M. Stationery Office, 9d. net). Rest pauses, unless arranged as part of the routine of a factory, may be either voluntary or involuntary, the latter being due to such causes as lack of material, the intervention of other workers in removing accumulated products, and so on. Voluntary rest pauses in light repetitive work occur generally as the result of boredom and monotony rather than from fatigue. But in heavy muscular effort the pauses are literally rests, and serve for recovery from physiological fatigue. The occupations investigated by Dr. Vernon and his colleagues ranged from moderately heavy work in agriculture, road-making, dock labour in unloading, and bootmaking, to pitch loading, coal mining, and, heaviest work of all those investigated, tinplate rolling. The rest pauses of the agricultural labourer, who plods his weary way in solitude, are naturally all voluntary. The ploughman pauses at the end of each furrow, and in this way consumes 14.6 minutes in each hour of work. In the lighter work of harrowing or rolling the rests average 8.1 minutes an hour, and are not taken with the same regularity as in ploughing. In many occupations the voluntary rest pauses are strikingly similar, and amount to about 11 minutes an hour. But in tinplate rolling the various processes involve a very large amount of involuntary pause, with the result that, while the voluntary rest pauses of the different workers employed are about 7 minutes, the involuntary pauses range from 7 to 23 minutes in each hour. The observers were surprised at the similarity of habit in rest pauses spontaneously adopted by groups of men employed in widely different occupations. They found that in the moderately heavy processes of bootmaking there was no sign of fatigue in the afternoon. They discovered that in pitch loading, in which payment at piece rate is an inducement to work, the men rested for about half their time, but undoubtedly put in a very hard day's work; and in coal getting they concluded that the most advantageous rest was one which lasted less than a minute, and that the involuntary rests forced on miners were unnecessarily long, and, as relief to fatigue, were wasted. The observers regarded this demonstration of the ineffectiveness of involuntary rests as the most important practical conclusion of their report. At the same time, the varied nature of the collier's work would make it quite impracticable to devise for them an artificial scheme of rest pauses.

THE SHORTCOMINGS OF THE PARENT.

"AND only parents' love," says Browning, "can last our lives." But the complaint of the psychologist seems to be that parents' love is too lasting, too masterful and overwhelming. The address given by Dr. J. R. Rees at the Child Study Society on March 17th was virtually a plea for a more detached attitude on the part of parents to their children. Parental errors, arising, not from neglect, but from fussiness combined with ignorance, accounted, said Dr. Rees, for numerous problems concerning the individual in after-life. It was extraordinarily difficult to convince parents that to bring up a child required much learning, a capacity for self-effacement, and the acceptance of a whole-time job. Parenthood was taken for granted, and though the terminology of the parental function and duty had been modernized, the old methods and mistakes were perpetuated. The grosser mistakes of spoiling were obvious. The foundation of hysteria in later life was often laid by the parent who took up the infant every time it cried, so that the child came to think there was something magical in a howl which secured for it immediate attention. The vast number of people who were afflicted with self-consciousness had most likely been placed on a pedestal by their parents, unduly praised to their faces, and presently, having been knocked off the pedestal by an unfeeling world, suffered from a sense of inferiority, and were perpetually striving to regain their former elevation. Dr. Rees said that the number of children afflicted with "nerves" was extraordinary, as was the number of parents who were actually proud of the fact that their children were highly strung, thinking that to have "nerves" was rather distinguished and interesting. These parents never realized that they were condemning themselves, and that the nervous child was no more a subject for pride than the lying or thieving child, and was very often the result of parental mishandling. In nine cases out of ten it was not the child, but the parent, who should be punished. Dr. Rees pleaded for a closer co-operation between parent and teacher. Part of the teacher's job was to understand the parent. He hardly ever met a teacher without hearing an exclamation about the "awfulness" of parents, nor a psychotherapist without a similar tale, generally more emphatically told. There should be conferences between parent and teacher over the child, and in really difficult cases the doctor or the psychologist might be brought in. Dr. Rees went on to say that the art of parenthood depended to a great extent on the art of being married. There could be no successful parenthood without successful marriage. Many "difficult" children came from homes where parents did not understand each other, where the conjugal adjustment had never been made, and thus no progressive atmosphere was created. To his mind the conjugal was more important than the parental side of marriage, if only because the former lasted throughout life, whereas the parental function ceased when the children went out into the world and got homes of their own. The conjugal side mattered more than the parental, except perhaps during the months of pregnancy and of nursing the child, yet many women had the idea that being married was an incident only, and that mothering was the really important thing. Women had a difficult time over this problem, and few solved it. He believed that a good

deal of morning vomiting during pregnancy and other upsets was due to interior conflict over the adjustment of the parental and conjugal relations. Too often the mother became over-identified with her children—had them, so to speak, always on her own wave-length. The father did not come into the picture until the child was about 4, at which age the jealousy complex arose in the child, with efforts to detach one parent from the other, and this was likely to be successful where there was uneven discipline, where the parents failed to back each other up, and where there was competition for the child's favour. Parents, again, often made the mistake of not respecting their children enough. They looked upon them as others looked on a Pekinese dog, talked silly language with the idea of keeping the child young, failed to realize that the child was a logical little being, with thought processes as reasonable as their own. Parents often thought of a child, not as a prospective citizen committed to their charge, but as a possession which they had a right to manipulate and push about. If a parent resorted to disciplinary measures he should make it plain to the child that these were not imposed because he was offended and happened to be stronger and older, but because the social demand and responsibility had been infringed, and he, the parent, was the person who, for the time being, had to interpret this to the child. Much ill was wrought by parents who fussed and nagged their children, kept control over them in small matters, and refused to allow them to adventure, simply because they were not prepared to see their offspring make mistakes. Upon sex, too, they often looked as a narrow thing, a physiological process merely, instead of teaching their children that it was a large and splendid thing. Sex education, he considered, was not a job for the schools, though instruction in biology might be given there, but a job for the home. Sir John Cockburn, M.D., the president of the Child Study Society, who was in the chair, remarked upon the tendency he had observed for those brought up under strict parental discipline to be indulgent when they became parents themselves, and for their children in their turn to revert to an attitude of strictness; hence the frequent disharmony, of which the child took advantage, between parental and grandparental rule.

GLASS FRAGMENTS IN FOODSTUFFS.

IT may be gathered from a report just published by the Ministry of Health[1] that we may eat glass with impunity, and that famous mediaeval poisoners used powdered glass merely as a vehicle for the conveyance of more deadly things. Apparently public analysts were perturbed by the discovery of particles of glass in foods and drinks put up in glass containers. The Ministry, therefore, instructed Dr. G. C. Hancock to carry out an investigation; and he has now reported on the "Occurrence of glass fragments in foods packed in glass containers." Public analysts, it appears, have found glass in beer, mineral water, marmalade, jams, potted meats, and numerous other foods. In some cases such particles were found in 72 per cent. of the articles examined. Generally the particles were only 1/1000 or 1/2000 of an inch in size, but fragments as large as a quarter of an inch were sometimes found in jam. Did the glass come from the container? Dr. Hancock is not very clear on this point. Most food manufacturers, it appears, are well aware of the value of good glass, and for their own protection seek to avoid the possibility of contamination by broken bottles. The process of manufacture of cheap hand-made glass may leave splinters or fragments in the container. But most glass containers are now made by semi-automatic or completely automatic processes. "Returned empties" may have chipped and jagged rims; but measures are usually taken to eliminate such containers, and some firms use only new bottles or jars. Moreover, in some of the samples examined by Mr. Munro, an analytical chemist, the refractive index, tested with benzine, was found to differ from the refractive index of the glass container. It is suggested, therefore, in the report, that the dust in factories, with its particles of slag, which has all the properties of true glass, may be a source of contamination. And fruit on its way to the jam factory is bound to pick up a large quantity of dust. For the purposes of Dr. Hancock's investigation a series of microphotographs was prepared by Dr. Monier-Williams. These show how glass particles may be differentiated from other siliceous material by means of polarized light. The microphotographs are reproduced at the end of the report; and the chunks of old red sandstone, glass, and other residue to be found in salmon and shrimp and anchovy pastes will shock the consumer of these delicacies. However, it is gratifying to learn from Dr. Hancock that, even if glass is an undesirable ingredient of food, there is little, if any, evidence that in powdered or microscopic form it has any injurious effect. As confirmatory evidence Dr. Hancock quotes the case of the young negro who ate half a dozen test tubes, two good sized lamp chimneys, a 4-oz. medicine bottle, two pieces of window glass, and three strips of coloured glass one inch wide and three inches long! The story will perhaps console those who expected something both definite and sensational in a report on this subject.

AN ANATOMICAL CONGRESS IN LONDON.

THE French Association des Anatomistes has arranged to hold its meeting in London on April 11th to 13th in association with the Anatomical Society of Great Britain and Ireland. The meeting will be held at University College, and about 150 members of the two societies are expected; as the French society includes anatomists from Belgium, Italy, Holland, Switzerland, Spain, Portugal, Poland, and Czecho-Slovakia, the congress promises to be of an international character, and the first of its kind held in Great Britain. On the evening of April 11th a conversazione will be held at University College, and on the following evening a reception at the Wellcome Historical Medical Museum. On April 13th there will be a dinner at King's College. Arrangements have been made for the members of the congress to visit Cambridge as the guests of Professor Wilson. During the congress a trade exhibition dealing with scientific appliances and other technical equipment for anatomical study will be held.

THE HUME-SPRY CASE.

WE conclude this week at page 600 our summarized report of the action brought by Mr. Hume-Spry against Dr. R. Percy Smith and Dr. A. H. Watson for damages for their alleged negligence in certifying him as insane. The case occupied fifteen days in the King's Bench Division before Mr. Justice McCardie and a special jury, and, as most people who followed the proceedings at all closely had anticipated, it ended in a verdict for the defendants, with costs. The jury, in fact, by their action in stopping the case after a patient hearing, clearly intimated their opinion, not only that the two defendants, Dr. Percy Smith and Dr. Watson, had acted *bona fide* and with reasonable care in certifying the plaintiff, but also that the insinuations which the plaintiff had instructed his counsel to make were wholly without foundation. The judge's own view of the plaintiff's evidence is clear from his remark to the effect that the documents in the case would be held at the disposal of the Director of Public Prosecutions. We congratulate Dr. Percy Smith and Dr. Watson on the outcome of their protracted ordeal. Our comments on other aspects of the case must be deferred to a later issue.

THE AUSTRALASIAN MEDICAL CONGRESS
OF THE
BRITISH MEDICAL ASSOCIATION,
DUNEDIN, NEW ZEALAND.

INAUGURAL CEREMONIES.

THE second Australasian Medical Congress of the British Medical Association was held in Dunedin from February 3rd to 10th. The first, it may be remembered, was held in Melbourne in November, 1923.* The proceedings at Dunedin took place in the Medical School Buildings, King Street, while demonstrations of cases and operations were given in the Dunedin Hospital immediately opposite, and in the new Dental School close by. The session was a great success from every point of view. Nearly 600 members of the medical profession were in attendance, representing every State of Australia and New Zealand; and there were present, in addition, Dr. Cooper Pattin, accredited representative of the British Medical Association in the British Isles, and Dr. George Piness of Los Angeles, medical representative of the United States of America. The meeting of the Congress in Dunedin—the first since 1896—roused great interest, more especially as the University of Otago with its medical school is the centre of medical education in New Zealand; visiting members spoke very highly of the warmth of their reception, and of the boundless hospitality shown to them.

OPENING OF NEW MEDICAL SCHOOL BLOCK.

The Medical School Buildings, in which most of the proceedings were located, consist of two blocks. The latter and larger of these is a new structure, just completed in time for the opening of the Congress. The opening ceremonies on February 2nd formed, therefore, a highly appropriate preliminary to the Congress proceedings. The formal ceremony was performed by the Acting Premier, the Hon. W. Downie Stewart, in presence of the Chancellor of the Otago University, Mr. T. K. Sidey, M.P., and a large gathering of members of the University Council and staff and of Dunedin citizens, together with a number of visiting members of the Medical Congress.

The CHANCELLOR, who presided, expressed his pleasure at the presence of several oversea members of the Congress, and on behalf of the University tendered a hearty welcome to them. The first steps, he said, towards the establishment of a medical school in connexion with the University of Otago were taken in 1872; but for a considerable time after its foundation the school had provided only for a portion of the degree course, the students having to go to Britain to complete their medical training. It was not till 1883 that the complete medical course was provided, and the first medical student graduated in 1887. Since then the number of medical graduates had risen to 667, apart from a considerable number of graduates of other universities who had taken part of their course in Otago. During its early years the school had been financed almost wholly by provincial funds and private donations, but its rapid growth had compelled the University Council to seek Government assistance. He thanked the Government for having rendered possible the construction of the much-needed new building, and the completion of the medical scheme which brought all the departments of the school to one centre, in close proximity to the clinical material of the hospital.

The ACTING PREMIER, in declaring the school open, and in congratulating the University and the city on the fine building just erected, referred to the great interest taken by the city of Dunedin and the province of Otago in the Medical School since its foundation, as shown in the practical financial support that had always been forthcoming. The present building was the result of unceasing efforts and long negotiations of the University Council with the Government. Mr. Stewart spoke also of the unquenchable enthusiasm with which the Dean of the Medical Faculty, Sir H. Lindo Ferguson, had striven for the advancement of the school. "I congratulate the Medical Faculty," said Mr. Stewart, "which is now housed in ample space for effectively and properly educating the students in medicine. In my opinion, no profession is better warranted in that direction than the medical profession. In the earliest days, when this school was struggling into existence and towards further success, the leading medical men of Dunedin put their medical services without reserve at the council's disposal for the purpose of assisting the students by personal and voluntary services. In that respect they were a shining example to other professions in New Zealand."

Speeches were also delivered by the DEAN of the Medical Faculty and by Dr. L. E. BARNETT, President of the Australasian Medical Congress.

The new building is a commodious and imposing structure of three floors and a basement, and is connected with the older block by a passage-way on the first floor. Its construction enables the departments of anatomy and physiology, which had hitherto been located in the University Buildings in Leith Street, and which, in spite of several extensions, had outgrown their old quarters, to be grouped alongside the other medical departments in one centre opposite the hospital. The sub-departments of histology, biochemistry, and pharmacology are also provided for. The greater part of the second and third floors is devoted to anatomy, with dissecting-room, lecture-rooms, museum, library, and professors' and demonstrators' rooms. The first floor is allocated to physiology, the chief rooms being those for junior physiological chemistry, with a chemical preparation room adjoining, two lecture-rooms, rooms for advanced physiological chemistry, gas analysis, food analysis, library, tutorial work, and research.

The ground floor has an imposing entrance and stair hall, in which a prominent figure is the bronze bust of Lister which had been on view at the recent New Zealand and South Seas Exhibition, and which was presented to the school by Mr. Edmond Andscombe, the exhibition and university architect. On this floor are placed the general offices, waiting-rooms, men's and women's common-rooms, junior experimental room, experimental demonstration room, experimental research rooms, preparation room, rooms for experimental physiology, and rooms for the professors of medicine, clinical medicine, and surgery.

The basement extends over the whole area. The anatomy section accommodates the mortuary, workshop, storage tank, refrigerating chamber and plant, bone room, and modeller's room. The physiology part contains the animal room, rooms for vitamin and nutrition work, electrocardiograph and x-ray room.

The whole building is heated by low-pressure steam and lighted by electricity. The cost of the building alone was £110,000.

INAUGURAL CEREMONY.

The inaugural meeting of the Congress, held on Thursday evening, February 3rd, in the Early Settlers' Hall, was one of the most brilliant and impressive functions which Dunedin has known for many years. The entrance to the hall was specially illuminated with a brilliant electric sign bearing the word "Welcome," and the interior was decorated with draped flags, with massed foliage and flowers on the platform, while the entrance halls were embowered in New Zealand ferns and greenery.

* BRITISH MEDICAL JOURNAL, 1924, vol. i, pp. 30, 71, 125, 165, 201, 340.

On the platform were the Hon. S. S. Argyle, Dr. George Piness (Los Angeles), Dr. J. Macmillan Brown (Chancellor of the New Zealand University), Dr. F. Antill Pockley, the Hon. W. Downie Stewart (Acting Premier of New Zealand), Dr. L. E. Barnett (President of Congress), Sir George Syme (retiring President), the Hon. J. A. Young (Minister of Health), Dr. A. C. Purchas, Mr. T. K. Sidey, M.P. (Chancellor of the Otago University), Dr. H. Cooper Pattin (Norwich), Mr. H. L. Tapley (Mayor of Dunedin), Mr. H. S. Newland, Dr. R. H. Pulleine, Dr. R. Wade, Mr. B. Kilvington, Dr. Dunbar Hooper, Sir H. Lindo Ferguson (Dean of the Medical Faculty), Dr. Jefferis Turner, Dr. T. A. Valintine (Director-General of Health, New Zealand), Dr. A. M. Morgan, Dr. A. L. Kenny, Dr. O. Latham, Dr. F. S. Batchelor (President of the New Zealand Branch, British Medical Association), Dr. A. H. Tebbutt, Dr. Harvey Sutton, Dr. S. A. Gibbs, Colonel Tracy-Inglis, Major-General Barber, Dr. R. H. Todd, Dr. H. E. Gibbs, Mr. N. D. Royle, Dr. J. S. Elliott. The large hall was filled to its upmost capacity with members and friends.

At 9 o'clock the retiring President, Sir GEORGE SYME, called upon the Hon. W. Downie Stewart, Acting Premier, to declare open the Second Session of the Australasian Medical Congress of the British Medical Association.

The Acting Premier's Speech.

The Hon. W. DOWNIE STEWART, welcoming on behalf of the Government those who were attending the Congress in Dunedin, expressed regret that the Prime Minister (the Right Hon. J. G. Coates) had not been able to return to New Zealand from the Imperial Conference in time to open the Congress. He had been pleased to hear from Dr. Barnett that quite a number of oversea visitors who were with them that night had been present at the last Dunedin Congress in 1896. Dr. Barnett was one of the very best type of New Zealand practitioners. In Australia and New Zealand the medical profession was known, not only for the very high standard of its own special work, but individually for its broad interest in public affairs, and particularly in supporting the fine arts—painting, music, literature—subjects too much neglected in small communities. In the world of medicine and surgery there were greater advances being made and greater movement of thought was manifest than in any other profession. Co-operation and consultation were becoming increasingly necessary; the institution of clinics and specialists was taking the place of the old family physician. Speaking particularly of the present Congress, Mr. Stewart maintained that in no other country in the world could such a congress be held in such happy and hopeful circumstances. New Zealand enjoyed an extraordinarily healthy and bracing climate, where health was not a Utopian dream, but a national ideal—an ideal capable of approximate realization. Her geographical configuration tended to the production of towns of moderate size and a well distributed population, and not of great metropolitan conglomerations with their vice, crime, and squalor. Her pioneers had come from the best British stock, and were resourceful and capable. She had no racial troubles. The Maoris were happy and contented, and were the only native race which, in contact with Europeans, was not declining: on the contrary, they were increasing and prospering.

Mr. Stewart then declared the Congress open.

Address by the Minister of Health.

The Hon. J. A. YOUNG (Minister of Health) said that it was a great compliment to New Zealand that this Congress was so well attended. He read a message from the Right Hon. S. M. Bruce, Prime Minister of Australia, who had just passed through Auckland on his way home from the Imperial Conference in London. The message read as follows: "On behalf of the Government and people of the Commonwealth of Australia I desire to extend to the Australasian Medical Congress best wishes for success. Thanks to the unremitting efforts of the public-spirited members of their great profession, our citizens are realizing the part which health plays in every aspect of our national life, and the enormous economic waste occasioned by the inefficiency of the partly unfit. I hope, and indeed I feel sure, that the labours of the Congress will advance us still further towards the accomplishable ideal of a happy, prosperous, and healthy community." Mr. Young added that there was great opportunity for co-operation between the medical profession and the State; the State had the great responsibility of teaching the people by legislation so to act that they might escape the pitfalls of disease, and avoid exposing their fellow-citizens to needless sufferings by ignoring elementary rules of health.

Sir George Syme's Speech.

The retiring PRESIDENT said that it was exactly forty years since the thought had occurred to Dr. Fulton of Adelaide that it would be a very good thing to have gatherings of the medical practitioners of Australia and New Zealand in congress. The idea was very warmly supported by the profession in South Australia, and materialized in the first session of what was then called the Intercolonial Medical Congress, under the presidency of Dr. (now Sir) Joseph Vercoe, who was still active in his service to the community and to the profession. Since then a series of congresses had been held under other presidents. Sir Joseph Vercoe, an eminent physician, was followed by an equally eminent surgeon, Sir Thomas Fitzgerald; and in turn the position had been held by university professors, by general practitioners, and by specialists. He congratulated Dr. Barnett on being nominated by the New Zealand Branch and appointed by the Federal Committee of the British Medical Association in Australia to the position of President. Those who had been present at the Congress in Dunedin in 1896 regarded that meeting as the high-water mark of all congresses before or since; he was confident that the present Congress would equal its predecessor.

Sir George Syme then inducted Dr. L. E. Barnett, C.M.G., M.B., C.M., F.R.C.S., to the position of President of the Congress.

THE PRESIDENT'S ADDRESS.

In the course of his address the PRESIDENT said:

"The Australasian Medical Congress, since its inception in 1896, was held every three years, independently of any other organization; but, beginning with the medical congress in Melbourne a little over three years ago, it has merged itself voluntarily, and I think wisely, in the British Medical Association. It had thus become part of a great imperial scientific institution, of which the King is patron. Though the majority of the people are of the same opinion as their sovereign in regard to the maintenance of the high ideals and traditions of medical practice, yet we have repeated and very obvious indications that there are quite a number of people who do not see eye to eye with us, and we have to face at times very bitter antagonism towards a policy that has been devised conscientiously and with infinite pains to safeguard the interests of the general public equally with those of ourselves.

Medical Ideals and Lay Criticism.

"There are many who mock and deride us for our subservience to what they call a ridiculous code of medical etiquette. There are some who criticize us in frank and fearless fashion, but withal reasonably, and often usefully. Hostile criticism, if it is reasonable, has a more purifying and stimulating effect than friendly adulation. 'A friendly eye does never see such faults,' and the medical profession makes no claim to be faultless. Our little medical parliaments are as liable as the greater parliaments of the people to make blunders, and that is certainly a fair admission of human limitations, of human error, of human frailty. Criticism by an opposition party is a good thing in the people's parliament, just as it is a good thing in the parliament that deals with the doings of doctors. We must give consideration to the honest and reasonable criticism of the opponents of our policy, whether that

criticism comes from lay or medical sources. But we cannot help feeling resentment at the publication of gross and unwarranted statements that accuse us of rank dishonesty; allegations, for instance, that we are a great trade union, whose chief aim is to keep the wages of its doctor members at the highest possible level; that we strangle competition by keeping out of this union the numerous and wonderful unorthodox healers, who have not conformed to our requirements of a thorough medical education; that we advocate vaccinations, operations, inoculations, animal experiments, and so on, not for the sake of suffering humanity, but for the benefit of our sordid selves; that we only give gratuitous service to the hospitals and sick poor for the sake of prestige and a free advertisement—that is to say, we climb over the backs of the poor into the pockets of the rich.

"I have the impression that these intensely bitter and vociferous critics of ours are not only mentally, perversely active, but also abnormally healthy in body, and that, consequently, they have not had their crude conclusions confounded by any dangerous and painful malady, accompanied by the soothing ministrations of a capable doctor. We judge it wise to refrain from responding in the lay press to calumniations of this kind. The piquant controversies that otherwise would arise could produce nothing but confusion. We are quite prepared to be judged by the majority. Let our lives and our actions suffice to discredit our detractors.

"It has been said that human destiny is largely in the hands of the medical profession. Whether this be so or not, we must not fail to realize the sacred duty that devolves upon us—namely, the medical care of the most wonderfully beautiful and intricate living thing on earth—the human body, and with it the human mind, and even the human soul. We know that Nature, if unhindered by harmful customs imposed by a too luxurious civilization, can cure most illnesses and heal most wounds in human beings, just as is the rule in lower animals. We know, and we preach, that if people lived a more natural life, from the pre-natal stage onwards through babyhood to adult life—if they took more advantage of those priceless tonics sunshine and clean, dust-free air; if feeding was more rational as regards quality, quantity, temperature, and periodicity; if the drinking of alcohol was not abused; if teeth were looked after and food well masticated, and if they earned their meals by a fair measure of exercise—there would then be much less necessity to resort to the ministrations of the physician and the surgeon, to the nostrums and cure-alls of the proprietary drug vendors, or to the hocus-pocus of quackery.

"But we doctors know that there remains a considerable and serious proportion of cases of illness, virulent microbic infections, tumours and cancers, grievous injuries and mechanical disabilities which Nature unaided cannot cope with—troubles which may at first seem slight and unimportant, but which have tragic possibilities, and which may be overwhelming from the very outset. Not individuals alone, but whole communities, suffer disaster if troubles of this degree of gravity are allowed to progress unchecked. Disease and degeneration, injuries and ill habits, and other health-destroying agencies are numerous and often complex, obscure, and difficult to control. To prevent and to conquer these malign influences and to repair the ravages of illness and injury, a defending army of selected, educated, and trained doctors has been organized—an army which has for its headquarters staff, its board of control, its disciplinary body, the General Medical Council and the British Medical Association.

"These assemblies have always included medical representatives of eminence and special fitness for their duties. Quite recently, in deference to public opinion, a lay member has been added to the General Medical Council—namely, Commander Hilton Young, a distinguished English politician and one of the heroes of the Zeebrugge naval attack. Lay representation on the Council is, I think, a wise provision, calculated to allay public distrust in the pronouncements of that important body.

"We have, in the course of long years, evolved a scheme of medical education and training, of efficiency examinations, of ethical regulations, of safeguards against injustice, of post-graduate study and research, of preventive measures for the lessening of disease and the control of epidemics. We benefit in many ways by such a scheme, but the public benefit still more. We have the public welfare at heart just as much as, if not more than, our own, and that is a point which deserves reiteration.

"Moreover, we do not try to interfere with public liberty. A sick man, or a man who thinks he is sick, is not bound to come to one of us for treatment. He can choose a layman if he wants to—he can have the drains of his own precious body—his stomach, his bowels, his kidneys, and whatnot—tinkered with by an ill-educated self-styled healer who has not the haziest idea of the intricate mechanism of these essential organs; yet if he wants the pipes, drains, or sewers of his house looked to, the law insists that he must employ a man specially trained and certified for the job—paradoxical but true.

Cancer Research.

"We shall endeavour to stimulate and correlate cancer research in the various Australasian centres. Although far more cases of cancer are cured now by operative and radiological means than in former years, chiefly because the patients are learning the wisdom of seeking treatment when the disease is in its early stage, yet, owing to the increasing prevalence of this still mysterious malady, the total death rate from cancer keeps mounting higher and higher. The cancer problem is still with us, but ever nearing solution as a result of intensive labour in a hundred fields.

"I take this opportunity of congratulating Sydney University on the generous response of the people of New South Wales to its appeal for a Cancer Campaign Fund. With a sum of well over £100,000, a splendid plan of research can be instituted, and I only hope that other scientific centres in Australasia, including Dunedin, may have the same good fortune.

Research in Public Health.

"The Governments in every civilized country now regard it as their bounden duty to encourage research that has for its object the betterment of the public health. The Royal Commission on Health for Australia, so ably presided over by Sir George Syme, has recently reported the conclusions of one of the most valuable investigations into public health matters that have ever been made, and one of its recommendations, and a very significant one, is that a health research council should be established and provided with an endowment of £30,000 per annum.

"We shall at our meetings give detailed attention to the important subjects of maternal and infantile mortality, of tuberculosis, and of certain tropical diseases of great public concern in Northern Australia and the Pacific Islands; to questions concerning diet in health and sickness, and to many other matters of special interest from the preventive medicine point of view.

The Australasian College of Surgeons.

"I must refer also—and I do it in optimistic vein—to the proposed inauguration, during the currency of this Congress, of the Australasian College of Surgeons, because I believe that such a college is likely to have a valuable influence on the public welfare, and because I have for some years been trying to mould professional feeling in New Zealand towards something of this kind. The promoters will endeavour to combine the good points of the Royal Colleges of Surgeons of the British Isles with those of the more recently founded American College. The aims are to raise the standard of surgical efficiency, surgical endeavour, and surgical ethics in both hospital and private practice, and to encourage the provision of facilities in hospitals whereby a sufficient number of suitable men can be specially trained to undertake the responsible duties of a surgeon.

"In Great Britain it is quite exceptional for anyone without special training and experience to do major operations, but in the newer countries, like America, Australia, and New Zealand, there is not the same restriction. In these countries major operative work is quite commonly

undertaken by men who, though adequately equipped with what is popularly called 'nerve,' lack, in varying degree, that knowledge and experience which are requisite in deciding such questions as: (1) Is an operation really necessary? (2) When should the operation be performed? (3) How are the unanticipated difficulties and complications to be handled? (4) How should the scope of the operation be limited or extended according to circumstances? I do not insinuate that the only competent surgeons will be those who are Fellows of a college. For various reasons a man who really is a good surgeon may not wish, or may not be in a position, to obtain a hall-mark of this kind. The patient's choice will be unfettered. If he selects an operator who is not a Fellow of a college he may or may not get a properly trained man, but if he does choose a Fellow of a college he can rest assured that he has the services of a fully trained surgeon.

Hospital Appointments.

"The greatest care should be exercised in the selection of the junior and senior staffs of our hospitals for many reasons, and one of them has to do with the supply of trained surgeons to the community. The recognized recipe for the making of a surgeon is to take a young man who shows both intellectual ability and manual dexterity, and place him in an approved hospital, first as a house-surgeon, and then as assistant surgeon for several years. The passing of a high-grade academic examination is desirable, but is not essential to the performance of high-grade surgery. The main thing is good hospital work, at first under supervision, and later independently.

"Painstaking, skilful, and kindly hospital work does materially help in the building up of the very best class of private practice. But the kind of advertisement a hospital gives is similar to that of a shop window, exhibited, however, not to the public generally, but to those only who know the worth of the articles displayed. When a surgeon or a physician habitually shows work of good quality within a hospital it is appraised accordingly by competent observers—that is to say, by his colleagues, his students, and his nurses. If, on the other hand, his work is habitually faulty, then, instead of a good advertisement, he gets a bad one. A hospital appointment may place a man in consultant rank, but only if he is worthy of it. The public benefit enormously by this automatic method of grading medical practitioners through the medium of their gratuitous hospital service.

"Modifications in our hospital systems are now receiving serious consideration, largely stimulated by the investigations and reports of Dr. MacEachern, the American expert on hospital standardization. I hope that many of his valuable suggestions will be adopted, and, in particular, I would like to see our public hospitals made available to all classes, but with the proviso that the sick poor shall continue to have the gratuitous services of an honorary staff, in accordance with the honourable traditions of the profession. For in this, as in all things, we must jealously guard the great heritage of public esteem and public confidence that we owe to our predecessors."

At the conclusion of the presidential address the visitors and their friends attended a reception by Dr. and Mrs. Barnett in the adjoining Art Gallery Hall.

SOCIAL EVENTS.

Congress week was a very full one. The various proceedings were entered into with great interest and enthusiasm by members, and the sectional meetings brought forth many able papers and keen discussions. The many social events were well organized and highly appreciated. An official Congress dinner was held at the Fernhill Club, and sectional dinners were held at the Fernhill, Otago, and University Clubs. A medical women's dinner was held at the Carlton Hotel. Members were also entertained at various private dinners throughout the city. Garden parties or "at homes" were given by Mr. T. K. Sidey (Chancellor of Otago University) and Mrs. Sidey, by Sir John Roberts and Mrs. George Roberts, by Sir Lindo and Lady Ferguson, by Mrs. North, Mrs. Edmond, and others. There were also several cabaret evenings, and bridge, tennis, and golf parties for the ladies. On February 6th the Mayor and City Council organized a motor excursion to Waipori for about one hundred members, and a special train took large parties to various doctors' seaside residences at Waitati and Warrington. Dr. Gribben (medical superintendent of Seacliff Mental Hospital) and Mrs. Gribben entertained the members of the Neurological Section at lunch at Seacliff. A popular lecture by Dr. Peter Buck (Te Rangi Hiroa), director of Maori hygiene, on the subject "The coming of the Maori," was one of the most interesting of outside events.

A very extensive trade exhibit by well known British, American, Australian, and New Zealand firms occupied most of the ground floor of the Medical School buildings.

The Congress Museum was organized under the direction of Professor F. Gordon Bell, and besides showing a number of interesting pathological conditions contained many original wax models of anatomical conditions. There was an interesting display of plastic surgery, and relics of former congresses were also on view.

The general organization of the Congress was the subject of very favourable comment by visiting members of the Congress, and special credit was bestowed on the "inner executive"—the President (Dr. L. E. Barnett), Dr. W. P. Gowland (Honorary General Secretary), Dr. A. M. Drennan (Honorary Associate Secretary), and Dr. D. W. Carmalt-Jones (Honorary Treasurer).

The scientific and clinical work of the Congress was shared by twelve sections—namely, medicine; surgery; obstetrics and gynaecology; pathology; preventive medicine; ophthalmology; otology, rhinology, and laryngology; neurology; pediatrics; naval and military; orthopaedics; and radiology. We shall publish an account of the proceedings of these sections in an early issue.

Nova et Vetera.

QUEEN SQUARE.

In an interesting book with the above title[1] the Secretary of the National Hospital for the relief and cure of diseases of the nervous system makes a pleasant contribution to the history of eighteenth century London. When, however, on the first page of the book he lays down the boundaries of what he imagines to be Bloomsbury, we most emphatically disagree and disapprove. "Queen Square, Bloomsbury," is a phrase used no doubt for the sake of distinction from other Queen or Queen's Squares, but it is incorrect. The name "Bloomsbury" has been very loosely used by many writers, but none, we think, have gone so far as Mr. Hamilton, who places its eastern boundary at Gray's Inn Road, and so includes Gray's Inn. Why stop there? Why not go on to the line of the Fleet ditch, or even further? The boundaries of Bloomsbury have been exact and well defined for more than six hundred years as the ancient manor of the Blemunds of Tottenhall, and later as part of the parish of St. Giles-in-the-Fields, and when the parish of St. George, Bloomsbury, was formed in 1724 it had the same boundaries as the ancient manor, and it has them to this day. Its eastern boundary corresponds to the east side of Southampton Row (which has swallowed up Kingsgate Street, where lived that irregular but popular obstetrician Mrs. Sarah Camp. Queen or Queen's Square (it has been known by both names) is therefore outside Bloomsbury. It was designed in Queen Anne's reign, but was not begun to be built till after her death, "at the north end of Devonshire Street, near Red Lion Square," as a contemporary described its position. The two squares are linked by more than names, for Alexander Pope, who went to a school in Devonshire Street, lay ill in later years in Cheselden's House in the Westminster Square. Many people have supposed that the statue in Queen Square, like that in Queen Anne's Gate, represents the good (but sluggish) Queen Anne. The mistake is natural, but, as Mr. Hamilton shows, it is beyond dispute that it is meant

[1] *Queen Square.* By Godfrey Heathcote Hamilton, Secretary, National Hospital, Queen Square. London: Leonard Parsons. 1926. (Med. 8vo, pp. xi + 146. 10s. 6d. net.)

for Queen Charlotte, the consort of George III at the time of its erection in 1775. The square was built upon part of what were known as the Conduit Fields. These fields seem to have been a well known playground. In Mist's *Weekly Journal* for May 16th, 1719, there is the following report:

"Last Week a Tryal was brought at Guildhall before the Lord Chief Justice Pratt, between two Companies of Cricket Players, the Men of Kent Plaintiffs, and the Men of London, Defendants, for Sixty Pounds played for at Cricket, and after a long Hearing, and near 200 l. expended in the Cause, my Lord not understanding the Game, ordered them to play it over again; and they met accordingly on Monday last in Lamb's-Conduit-Fields, but one of the Players being taken ill, it was deferred to another Opportunity."

No doubt the judicial ignorance was genuine and not assumed as has sometimes been the case in our time. Whether the match was ever replayed or no we cannot tell.

There appear to have been numerous conduits in this neighbourhood which collected water from springs and conveyed it to London through pipes. The term "conduit" was used to include the collecting cistern, generally housed in for protection, the pipe conveying the water, and the standard from which the water was drawn for distribution. Such a system is described in Stow's *Survey* thus:

"There lieth a street from Newgate west to the end of Turnagain Lane, and winding north to Oldborne Conduit. This conduit by Oldbourn (Holborn) Cross was first built 1498. But of late a new conduit was there built in place of the old, namely, in the year 1577, by William Lambe, sometime a gentleman of the chapel to King Henry VIII and afterward a citizen and clothworker of London. The water whereof he caused to be conveyed in lead from divers springs to one head and from thence to the said conduit, and waste of one cock at Oldborne Bridge more than two thousand yards in length. All of which was by him performed at his own charges, amounting to the sum of fifteen hundred pounds."

This was Lamb's Conduit, from which the northern continuation of Red Lion Street takes its name. An earlier conduit seems to have supplied the celebrated Greyfriars monastery—Eastminster, as Besant called it—which was situated in Newgate Street, where afterwards Christ's Hospital (now being itself forgotten) stood next to Christchurch. The White Conduit Fields, further to the north-east of Lamb's Conduit, were named after another water supply. One conduit head which survived until recently was situated in the garden of No. 20, Queen Square, and has been carefully taken to pieces, removed, and re-erected in the grounds of the Metropolitan Water Board at the New River Head in Rosebery Avenue. The only similar building—to the present writer's knowledge—still existing in London is the ivy-covered water-house on the south side of Hyde Park, just inside the Knightsbridge railings, opposite the Alexandra Hotel. This was connected with the water supply of the Abbey and Palace of Westminster, and is undoubtedly the oldest building in the neighbourhood. One of the difficulties of supplying London with water in this way was caused by land and house owners through whose property the pipes passed tapping them and drawing off water, so that in one case there was no longer any flow at the standard or conduit in the city.

At the beginning of the eighteenth century, when Queen Square was planned, the buildings of Bloomsbury proper did not extend north of Great Russell Street; but east of what is now known as Southampton Row building operations had reached further northward up to the line of Great Ormond Street or thereabouts. Southampton House and its garden occupied the whole of the north side of Southampton (since called Bloomsbury) Square, and when, by marriage, the Russells inherited the property of the Wriothesleys this house became known as Bedford House.

Bloomsbury Square has medical interest, for in it Radcliffe and Mead and Sir Hans Sloane dwelt and practised. Mead afterwards moved to the house in Great Ormond Street, close to Powis House, in which the Hospital for Sick Children was afterwards established, much helped on by a former occupant of Tavistock House, Charles Dickens.

All through the eighteenth century the Russells enjoyed an uninterrupted view of Highgate and Hampstead from the back windows and garden of Bedford House across the Long Fields, parts of which afterwards became Russell Square. Only one building of any size can have obtruded itself on their view. This was Baltimore House, built in 1763 by Frederick Calvert, sixth and last Earl of Baltimore. This bold bad man seems to have been of the Surrey melodrama type:

"Can I forget those wicked lords
Their voices and their calves
The things they did upon those boards
And never did by halves?"

This particular wicked earl became notorious for his goings-on in this house, to which he decoyed a Miss Woodcock of Tower Hill and detained her for some days, during which he made repeated attempts at seduction, and at length carried her off by force to his house near Epsom, where he effected his purpose by foul means. He was tried for rape at Kingston Assizes in 1768, but acquitted. An intelligent jury, having found him not guilty, wanted to record a verdict of guilty against some of his servants, who were charged as accessories. Perhaps they thought rape was allowable in an earl, but not in plebeians. Lord Baltimore died three years later and left his immense property in the State of Maryland to a boy, named Henry Harford. The house still stands, much altered, at the southern corner of Guilford Street and Russell Square, within a stone's throw of Queen Square.

"Queen Square, Bloomsbury . . . seems to have been set apart for the humanities of life and the alleviation of all hard destinies." Thus wrote Robert Louis Stevenson, and even now that the Alexandra Hospital for Hip Disease has left it, there are enough hospitals and offices of philanthropic agencies to make good Stevenson's statement, although some people may question the suitability of his description when applied to the Examination Hall of the Royal Colleges. But even there they temper justice with mercy and are cruel only to be kind.

The neighbourhood was never aristocratic as Mayfair, Portman Square, and Belgravia have been, but in it and the older part of Bloomsbury lived leading men in law, medicine, and science. Dr. Anthony Askew came to live in Queen Square in order to be near Mead in Great Ormond Street. Askew was more distinguished as a classical scholar than as a physician, and, like Mead, he left a great collection of classical literature and Radcliffe's celebrated gold-headed cane, which he inherited from Mead and passed on to Pitcairn and Baillie, whose widow presented it to the Royal College of Physicians. Later medical residents of the square have been Sir Rickman Godlee and Hughlings Jackson. Dr. Charles Burney, the father of Fanny and the historian of music, and William Morris represent art among the former inhabitants.

It is a pity that so many of the fine old houses of Queen Square should have been condemned as insecure and therefore pulled down and rebuilt, not always in styles in keeping with their older neighbours. The pity is the greater because the sacrifice was probably unnecessary. Sir Francis Fox tells us in his book of reminiscences how one of the old houses in Great Ormond Street, occupied by the Hospital for Sick Children, was condemned as unsafe, and how the committee of the hospital, faced by the prospect of an outlay of many thousands of pounds, appealed to him. He was able, by applying the system of grouting which saved Winchester Cathedral, to save this house and render it stronger than it had ever before been, for a fraction of the cost of destruction and rebuilding.

When St. George's, Bloomsbury, was made a separate parish from St. Giles-in-the-Fields and St. George-the-Martyr was cut out of St. Andrew's, Holborn, the growing population made new burying grounds necessary, and accordingly sixteen acres of meadow land were obtained a little to the west of Gray's Inn Lane and consecrated for the use of the two new parishes. These cemeteries are now known as St. George's Gardens. Here various notabilities were buried, from Nancy Dawson the hornpipe dancer to Zachary Macaulay, whose famous son once lived in Queen Square. This Bloomsbury graveyard was the scene of the Resurrectionists' activities which occasioned the first prosecution for such an offence in England. In 1777 the gravedigger and his assistant, and also a woman, were

tried, under an indictment for a misdemeanour, at the Westminster Guildhall before Sir J. Hawkins for stealing the dead body of Mrs. Jane Sainsbury, who had been buried nearly two months before. The woman was acquitted, but the men were convicted and sentenced to the savage punishment of six months' imprisonment and to be each severely whipped twice in the last week of their confinement from Kingsgate Street to Dyott Street, which is full half a mile—in fact, along the whole of the southern boundary of the parish—but the whipping was afterwards remitted. Had they been convicted of stealing anything with the body they would have been guilty of felony and would have suffered a much greater punishment. In a small house at the end of Handel Street, abutting on the graveyard wall, was Cooke's School of Anatomy, the last survivor of the once flourishing private medical schools, which were killed by the regulations of the College of Surgeons. Until quite recently this school was licensed under the Anatomy Act, and here anyone could, on payment, study practical anatomy and dissect without being or becoming a medical student. Mr. Cooke was for some years on the staff of the Westminster Hospital, and his *Tablets* of anatomical and physiological facts in a concise form may have been familiar to some among the older generations of our readers. In this building recently two men were found dead from poisoning by illuminating gas, and the inquiry into the circumstances of their death afforded occasion for much speculation and profit to the "yellow" press.

Mr. Hamilton's book contains much that is of great interest and abounds in reproductions of old prints and modern photographs of the neighbourhood. It forms a valuable addition to the fast-growing library of books about London.

THE GOVERNMENT ACTUARY ON NATIONAL HEALTH INSURANCE.

[FROM A CORRESPONDENT.]

AT a meeting of the Royal Statistical Society on March 15th Sir ALFRED WATSON, K.C.B., Government Actuary, read a paper entitled "National health insurance: a statistical review," which will interest many readers other than professed statisticians.*

The evidence adduced that the sickness experience of males was becoming more favourable is very important. Sir Alfred Watson has analysed a thoroughly representative sample of the national experience of 1921-23 and compared the results with those of the registered friendly societies in 1876-80, and of the Manchester Unity of 1893-97. For reasons either stated in the paper or elicited by the discussion, he is of opinion that these three experiences are fairly comparable. He does not think that the omission from the national experience of sickness lasting not more than three days, which was included in the old friendly societies' experience, seriously impairs comparability. Again, the method of taking the sample for 1921-23 virtually excluded that class of insured person which does not claim sickness benefit. Assuming comparability, the results of comparison are remarkable. The friendly societies' experiences, which may be taken as typical of the conditions of the industrial classes fifty and thirty years ago, were practically identical. Between the ages of 20 to 24 and 55 to 59 the sickness rates per annum hardly differed in the two series. But the national experience of 1921-23 was far more favourable. Thus at 40 to 44 the rate of sickness per annum was 1.08 weeks in 1876-80, 1.07 in 1893-97, 0.80 in 1921-23. At 45 to 49 the rates were 1,28, 1.23, and 0.90. At the oldest age in the table, 60 to 64, the rates were 2.51, 2.30, and 1.85.

Sir Alfred Watson comments as follows:

"If, as must be believed, the relatively favourable experience of the most recent period is dissociated from any continuous decline having its origin in the early years of the century, or even previously, it must apparently be ascribed to conditions special to the period in which it has emerged. Some may find such conditions in the increasing efficacy of medical benefit as provided by the Insurance Act and the regulations thereunder. Others may ascribe the change, in part at any rate, to conditions set up by the war and, in particular, to the increase in the cost of living with which the sickness benefit provided under the Act, though substantially augmented in 1920, has scarcely kept pace. While the claims have risen since 1923, as shown by Table III, the comparison which Table IV provides is such as to afford strong grounds for hope that the sickness intensity shown by the experiences of the friendly societies in the later years of the nineteenth century will not again be reached. So much at least should have been secured to us by the advancements in the twin sciences of medicine and surgery, in the practice of sanitation, and in individual education, with which this generation has been blessed."

It is to be hoped (although not expected) that those critics of their fellows who have in some instances not hesitated to "explain" excessive local rates of sickness as due to malingering, abetted by medical men, will note the caution with which Sir Alfred Watson (who, in the course of his reply, gave a striking example of the injustice of some recent uncharitable interpretations of changing sickness rates) offers explanations of so striking a decline. We shall do well to imitate him in resisting the temptation to assign all the credit of the improvement to the medical profession. One point may, however, be noted. If the low sickness rate of the sample experience of 1921-23 were due to men unfit to work "sticking it out" for fear of losing employment or on account of the cost of living, we should expect an unfavourable influence to be exerted upon the death rates. No such effect can be discerned, so that although we cannot prove that *real*, as distinct from statistical, ill health is less to the extent the figures imply, there is certainly no inherently more plausible explanation. This is a very satisfactory result. Less satisfactory is Sir Alfred's demonstration of a heavier incidence of sickness upon women than upon men, particularly upon married women.

"The figures respecting married women" (he writes) "reveal conditions to which in its fullest import the word 'serious' applies. Not only are the claims among this section far more numerous, relatively to the numbers insured, than those of the unmarried, but at all ages up to 35 the average duration of the claims in the case of the married is in marked excess of that among the unmarried. It is not too much to suggest that an average duration of incapacity, within the year, of seven to eight weeks at practically all ages from 16 to 65 for every woman who is sick is disconcerting, and that such an experience in the case of the married women invites consideration of the fact that in the usual case the husband also is an industrial worker, and a portion only of the family earnings is suspended when the woman ceases to work."

An obvious suggestion—namely, that married women who are industrially employed have a far heavier burden to shoulder than spinsters, may well be true, but the fact, disclosed by a tabulation of the separate years 1921, 1922, and 1923, that the ratio of the average duration of sickness benefit per insured married woman to the average per insured unmarried woman is increasing cannot be so explained. As Sir Alfred Watson remarks, "It is surely contrary to reason to suppose that the health of married women, as contrasted with that of their unmarried sisters, is deteriorating at this rapid rate."

There are many other points in this valuable paper to which attention might be called, but perhaps enough has been said to send readers to the original, which, not being thick-set with statistical algebra, can be read by any intelligent person. Some may have felt that, so far, too little use has been made of the national health insurance experience for the elucidation of problems of national health other than those of finance. Sir Alfred Watson has given an excellent example of what is possible on these lines. It is to be hoped that he and his colleagues will give many more papers similar to this one. From the nature of the case, the private investigator cannot achieve much, although if insurance practitioners had less to do and were more interested than most medical men are in statistical methods, their material might furnish data for very interesting papers.

* A summary of Sir Alfred Watson's paper appeared in last week's SUPPLEMENT, and further comment upon it will be found in the JOURNAL this week at p. 581.

France.

[FROM OUR OWN CORRESPONDENT.]

MEDICAL EDUCATION.

THE same problems face every country at the same time, and it is not surprising that the question of medical education should come to the front once more. A good deal of readjustment has taken place since the war, and the medical faculties in France have given up the old system which seemed to have been organized rather to turn out anatomists than medical men. Understanding that medicine relies more and more upon physiology and laboratories, the anatomical course has been reduced to the first year at the faculty. A very strenuous and full year it is for the poor student who has to face a severe examination at the end of the first academical year. It may be added that he is now under a system working like a steam-roller, his time-table being fixed. As a matter of fact, he has not even a right to be ill; if he misses a class three times he is not allowed to sit for the next examination. Aesculapius appears to be sceptical of Aesculapian excuses. The question goes far beyond that of organization. The whole system of education has been criticized at the Academy of Medicine.

First of all scientific preliminaries as actually taught in the Faculté des Sciences, prior to the student matriculating as medical, are far beyond the requirements of the average doctor. It is suggested that such teaching should be given by men who have received a medical training, and not merely by what we call "pure" scientists.

Then comes the most important and subversive move. The French system is, and has been, characterized by the fact that from the very start the student comes into contact with hospital patients. Before knowing anything of medicine he has to examine and to report on patients; the idea is that a good medical training means having seen as large a number of patients as possible. It may be that we should replace "seen" by "understood," and perhaps a great many useful hours are wasted in the wards. The new system proposes to control the non-initiated much more closely, but the number of students makes it necessary that there should be many more teachers, and that physicians in charge of hospitals should be recognized, if it be their desire, as such.

As all our hospital appointments are the result of competition, it is now asked that their programme should cease to be exclusively anatomy and theoretical medicine. The attention of the young students must be turned towards physiology, and they should prove, before taking charge of their ward laboratory, that they have some idea of the use of the instruments they are responsible for. This is not the case at the present time. A good memory is the essential requisite for the first competitive examinations. The result is that students try to secure the office first, and then learn how to make the best of it. The sooner the change comes the better.

The final question is how the body of teachers should be organized. Some would have teaching professors on the one hand and research professors on the other. It is quite a different proposition from that of whole-time professors, which has a very poor chance with us so far as medicine is concerned. How, it is asked, should the professorial staff be recruited? Many of us think that the competitive system is, as a matter of fact, very nearly an election; then why not let it be so openly?

If they will consider these few points, readers will come to the conclusion that the French system is gradually drawing nearer to the British, except that in no instance will there ever be, between our hospitals, the watertight compartments so characteristic of (and perhaps detrimental to) the latter.

HYGIENE IN FRANCE.

Alarming figures are given concerning the birth rate in France. The Government is taking steps to relieve the burden upon the shoulders of parents in allowing 50 million francs as premiums. Most of the money goes to the protection of the mother to assure care and rest at birth time. But the death rate is far too high, and we rank behind Great Britain, Holland, Germany, Sweden, and Denmark; 82 millions have been voted to fight the social scourges, 50 go to stamp out the slums, 25 to fight tuberculosis, 6 venereal diseases, and 1 cancer. The effort is far too small. For the sake of comparison, while Denmark spends 1s. 8d. a head on its antituberculosis campaign, France spends a little over one penny. Hygiene is sacrificed on the altar of the budget, and if "public health is the first concern of the statesman," as Disraeli put it, the French have still to learn that lesson.

THE LADY DOCTOR.

M. Delbet (professor of surgery in Paris) and M. André Pascal (otherwise Dr. Henri de Rothschild) have just staged a play called *La Vocation*. Its problem is what sort of a wife the lady practitioner will prove to be. The writers are evidently misogynists, for the poor husband (useless to say that a *tertia pars* appears in the play) is driven to suicide by the unfaithfulness of his wife. The play attracted both attention and protest. It seemed to some rather unfair that two medical men should try to prove their case by selecting a character almost incredibly exceptional. We are driven back to consider the stern reality and our daily experience. The great majority of our fair confreres act in a way exactly opposite to Professor Delbet's heroine. Their call is the great call: they marry the young doctor, and as soon as they are married they are pretty careful to leave the consulting-room entirely to their mate; they give up medicine very readily, and have no idea of competing with their husbands—more especially when the night bell rings. But that would not allow the concoction of a play.

G. MONOD.

Union of South Africa.

[FROM OUR CORRESPONDENT IN JOHANNESBURG.]

MEDICAL, DENTAL, AND PHARMACY BILL.

THIS bill has come before Parliament periodically for the past ten years, but has always been allowed to lapse before the conclusion of the session. Its urgency has been emphasized by the different Ministers who have successively tried to guide it through the House; but the concerted efforts of persons not at present on the medical or dental registers of the provinces to become registrable has, in the past, so delayed its passage that it had invariably to be dropped.

It is a bill to consolidate and amend the laws in force in the various provinces of the Union "relating to medical practitioners, dentists, chemists and druggists, midwives, nurses, masseurs, and other classes of persons; the keeping and sale of poisons; the importation, sale, and use of habit-forming drugs, and as to other matters connected therewith; and to provide for the extension of this Act to the mandated territory of South-West Africa."

The present session has opened calmly with few fresh measures, and at last the Medical, Dental, and Pharmacy Bill shows reasonable signs of becoming law. Much time has been allowed it in the House, and at this early stage of the session, not only has the second reading been survived, but the two most contentious clauses have been passed in committee.

The second reading was moved on February 7th by the Rev. Dr. Malan, Minister of Public Health, who spoke in Afrikaans. He would not, he said, repeat the arguments which had been used on the numerous previous occasions that the bill had been before the House; it was of so urgent a nature that its passage should be no longer delayed. The need for a consolidating measure had long been felt, and the Medical and Pharmacy Boards had, even before union, had a draft consolidating measure prepared. The present bill had been before no fewer than three select committees, which had taken evidence at considerable length from all persons concerned. The matter had become urgent for various, more particularly administrative, reasons. Medical services in general throughout the Union should be uniform. To-day each province had its own Medical and Pharmacy Acts; sixteen such Acts had at present to be administered by his department, which led to considerable confusion and expense. Since the first introduction of the bill two university medical faculties had been established in South Africa, and it was essential that the medical profession and the medical faculties should

stand on properly defined relations towards each other, which was not the case to-day. An essential matter was the bringing of the trade in poisons under proper legal control. It had been said that in no other country in the world was it so easy for a person to become possessed of poisons as in South Africa; the tracing of crimes due to *poisons was extremely difficult.* The time had come to give effect to one of the agreements arrived at under the Versailles treaty regarding the sale of opium. This agreement was being carried out to some extent by means of regulations; but this was a matter essentially to be dealt with by legislation. A most important point was the position in the mandated territory. The South-West administration had the right to pass its own laws, but the less difference there was between the laws of the South-West and the Union the better. South-West Africa to-day had no medical laws; nurses and maternity nurses need not even be registered. *The need for medical legislation was* realized by South-West Africa, and after correspondence with the administrator it was agreed that legislation of the Union should also be made to apply to the South-West Protectorate. It was necessary for dental practitioners to be protected. The lack of protection in the past had resulted in the arrival of a number of dental mechanics who were permitted to do nearly everything that the fully qualified man did. They were actually better off than the qualified man, who fell under the discipline of the medical councils, in that they were allowed to advertise; unfair competition was thus created. The bill made provision for the registration of qualified nurses and masseurs. Regarding maternity nurses a great step forward would be made. In the past the heavy infantile mortality had been due largely to unqualified nursing. The number of qualified maternity nurses, especially in the rural areas, was certainly insufficient, and such areas had to be provided for. In certain specified areas nobody would be allowed to practise as a maternity nurse for remuneration unless properly certified and registered. All members were agreed as to the usefulness of the bill, and it was 95 per cent. non-contentious. The clause providing penalties for unregistered practising was the most contentious. Unqualified persons had striven to obtain under the bill rights and privileges similar to those of qualified persons. The clause last year had read that no one not duly qualified would be allowed to practise "for gain, hire, or reward, direct or indirect, or for the expectation thereof." He had met the objections raised last year against the words "hire or reward, direct or indirect, or for the expectation thereof." These words do not now appear. A person would now only be liable if he carried on while unqualified to do so "for gain," the word "gain" being duly defined in the bill.

The Minister expressed the hope that since various objections raised last year had been met much of last year's discussion would be avoided. He was, however, to be disappointed. The same arguments in favour of the registration of persons who practised "unorthodox methods of healing"—osteopaths, chiropractors, naturopaths, cancer curers—were brought up. In the backveld there are many persons who are believed to possess herbal remedies for many ills, and several country members spoke feelingly on behalf of the good being done by these persons to simple folk. These alleged remedies, when their constitution has been revealed, have almost invariably proved to be compounded of entirely inert materials. In committee many amendments are being moved, but in the present comparative leisure of the House they are being relentlessly disposed of. One member moved the following amendment:

"Provided that any person not registered in accordance with this Act shall be entitled to treat a person who has been abandoned by a medical practitioner as incurable, and to charge for such treatment."

A division was demanded, and the amendment was defeated by 51 votes to 22. Eventually this, the most contentious clause, was passed without amendment; but the next two clauses evoked much discussion. They dealt with the penalties for practising as a dentist when unregistered, and the exemption of certain unregistered persons performing dental work prior to the commencement of the Act. By March 1st both these clauses had been adopted in committee. The remaining clauses (there are 97 in all) should be dealt with expeditiously.

Certain of the alterations made by the Minister to meet previous objections are not proving too acceptable to the medical profession. This applies particularly to the inclusion on the South African Medical Council of two laymen. *Nevertheless, the feeling in the profession is that if the* present bill becomes law South Africa will be provided with probably the best medical legislation in the world.

FOOD, DRUGS, AND DISINFECTANTS BILL.

Another long overdue measure, which in the present becalmed state of Parliament has a reasonable prospect of becoming law, is the

"bill to consolidate and amend the laws for preventing the importation or sale of foods or drugs which are unwholesome or adulterated or incorrectly or falsely described, and for regulating the labelling and sale and for preventing the incorrect or false description of disinfectants."

A consolidating measure of this kind is urgently required for administrative purposes. At present each of the four provinces has its own Act or ordinance, and there are often wide discrepancies between them. Further, their provisions are in many cases obsolete, and are easily evaded. This bill, on becoming law, will repeal the four existing provincial laws. It was introduced by the Minister of Public Health, by whose department the Act will be administered. The Secretary for Public Health, acting on the authority and instructions of the Minister, will be charged with the general execution and enforcement. As this bill is the result of consultation between experts and representatives of all parties concerned it should meet with little opposition.

HOSPITAL SURVEY COMMITTEE.

The applications for State-aided hospital provision all over the Union have become so numerous that it has proved quite impossible for the Government to comply in all cases. In certain districts this provision is entirely inadequate, while in others the provision is almost excessive. To have some guidance in dealing with the numerous applications from towns, the Minister of Public Health has appointed *a committee to make a hospital survey of the Union and* investigate the hospital requirements of each of the provinces. This committee will make suggestions as to future administration, more particularly regarding the possibility of linking up and co-ordinating the work of the various institutions, nursing organizations, dispensaries, and similar bodies. The chairman of this Government Committee is Sir Edward Thornton, Director of Medical Services, and senior assistant health officer for the Union. The members include Dr. A. H. Louw, medical superintendent of the Pretoria General Hospital, Mr. R. F. Smithers, Public Service Inspector, Mr. J. R. Booth, secretary of the Kimberley Hospital, and a lay representative in each province nominated by the administrator of the province. The committee has completed its inquiry in Natal, and is at present sitting in Pretoria. It will sit a week each in Bloemfontein and Capetown. Its recommendations will be of considerable value for Government as professional guidance. It is hoped that the delimitation of hospital areas, each with a well equipped central hospital, and subsidiary smaller hospitals of the cottage type, will result from this inquiry.

Scotland.

PARLIAMENTARY REPRESENTATION OF THE SCOTTISH UNIVERSITIES.

THE death of Sir Henry Craik has created a vacancy in the parliamentary representation of the four Scottish universities. At the last election, when Sir Henry Craik stood in the Conservative interest, he headed the poll with 7,188 votes. His colleagues were Mr. D. M. Cowan (Liberal), with 5,011 votes, and Sir George Berry, F.R.C.S.Ed. (also Conservative), with 3,781 votes. Mr. Cowan was head master of the Higher Grade School, North Kelvinside, Glasgow, and is therefore, like Sir Henry Craik, an authority on education. Sir George Berry is consulting ophthalmic surgeon to the Edinburgh Royal Infirmary, and

has held the office of President of the Royal College of Surgeons, Edinburgh. No definite steps have yet been taken in Scotland to find a successor to Sir Henry Craik, and none will be taken until the various political organizations there have had time to consider the situation. We understand, however, that Dr. C. O. Hawthorne has already been approached, and that he is willing to consider the possibility of becoming a candidate should a general desire be expressed that he should stand. Dr. Hawthorne, who was assistant to the professor of medicine in the University of Glasgow from 1887 to 1897, has long resided in London, was chairman of the council of the Medical Graduates' College and Polyclinic from 1909 to 1914, and holds the position of consulting physician to several hospitals. He is at present Deputy Chairman of the Representative Body, and Chairman of the Science Committee of the British Medical Association. As a possible candidate the name has also been mentioned of Mr. John Buchan, author and publisher, who, although a Scot by birth, is a graduate of the University of Oxford.

PREVENTION OF TUBERCULOSIS IN EDINBURGH.

At the annual meeting of the Royal Victoria Hospital Tuberculosis Trust, the President, Sir Ralph Anstruther, said that not only had a great deal of help been given to individuals, but the power of dealing with this disease was furthered from year to year by the operations of the Trust. Professor George M. Robertson, President of the Royal College of Physicians, said that a spirit of hopefulness permeated the report, which was a great contrast to the attitude of despair with which medical men had looked upon tuberculous disease some forty years ago when he commenced to practise medicine. He believed that there was no disease against which warfare had been so scientifically and systematically waged as against tuberculosis, and he thought that these methods might be a model for those concerned with other diseases to imitate. In this matter Edinburgh and the Royal Victoria Hospital Trust had led the way; the dairy farm it had established at Gracemount for the supply of tubercle-free milk had been a valuable object lession, so that there were now thirty other dairy farms supplying milk of this type. Again, there were far too many one- and two-roomed houses in Scotland as compared with England, for overcrowding was a most potent factor in the spread of tuberculous disease. Education in hygiene was essential for the public welfare and to lessen tuberculous disease, and no institution in the country had done more to educate the public and the medical profession than the Royal Victoria Hospital Tuberculosis Trust. Professor Sir Robert Philip, proposing a vote of thanks to the collectors for their services, referred to the hopes often raised by announcements in the press of cures for tuberculosis. He referred especially to a campaign in favour of a Swiss observer who five and a half years ago had made a promise to the speaker, as representing a powerful organization in this country, that he would submit a certain amount of his products for examination and testing. In spite of reminders, this promise had not been fulfilled, and he understood that similar promises had been made and unfulfilled to other workers. He thought it was high time that the world and the press should know the real facts in regard to this matter. The report of the Trust for 1926 refers to additions which have been made to the buildings at Southfield Sanatorium Colony, especially the completion of a sun-bath and the installation of artificial sunlight apparatus. It also refers to developments in connexion with the production of certified milk at Gracemount Farm. The ordinary income for the year was £4,328, and the expenditure £3,140.

MOSQUITOS IN SCOTLAND.

At a meeting of the Royal Society of Edinburgh, on March 14th, Professor J. H. Ashworth, F.R.S., gave an account of the distribution of anopheline mosquitos in Scotland, so far as had at present been ascertained, for search did not appear to have been made in half the counties of Scotland. Three species of anopheles occurred in Scotland as in England—namely, *maculipennis*, *bifurcatus*, and *plumbeus*. The first was known in four localities, all in the Highlands, but many more areas would have to be examined, and a careful inspection made of cowsheds, pigsties, stables, and outhouses, which the adult mosquitos of this species frequented, especially in dark corners. *A. bifurcatus* occurred in thirty-six localities and was widespread both in the Lowlands and in the Highlands. *A. plumbeus* had been found in eight localities, all near the east coast and its estuaries. The west of Scotland, with the exception of the Clyde area, was still practically unexamined. In England *A. maculipennis* had been found to be the most abundant of the three species; but in Scotland *A. bifurcatus* was apparently the most abundant and widespread, and severe effects often followed the bite of this species, as well as of *A. plumbeus*. The mosquito had been found for the first time in Scotland in 1908, in a garden in the Grange district of Edinburgh, and it was believed that the actual breeding place was in water lodging in holes in trees. Data were lacking as to which species of anopheles had acted as transmitter of the parasite of malaria in Scotland. The areas in which ague was common in the eighteenth century were unfortunately those as to the mosquitos of which little or nothing was yet known. There was, therefore, at present no basis available for a consideration of the present distribution of anopheles in relation to the former distribution of ague. With regard to recent years, the only case of indigenous malaria in Scotland was recorded in the report for 1919 of the medical officer of health for Glasgow. A visitor had gone from Glasgow to Kirriemuir on July 17th, 1919, and thirteen days after her return to Glasgow had an attack of benign tertian malaria. Troops were quartered at Kirriemuir at the time of the visit, and it was surmised that the mosquito may have acquired the parasite from an infected soldier.

MENTAL TESTS.

Mr. R. H. Thouless, M.A., Ph.D., lecturer on psychology at Glasgow University, in an address to the Royal Philosophical Society of Glasgow, said that the object of introducing practical work into the teaching of psychology was to give the student actual acquaintance with mental facts and to train him in scientific habits of thought and of investigation. The teacher of practical psychology must bear in mind the practical needs of his students, who would have to apply standardized tests rather than to carry out research experiments. Instruction in mental tests was, therefore, an important part of practical psychological training, and new tests were still being framed. A problem now engaging the attention of many psychologists was the discovery of tests for traits of temperament and character, so that these could be measured with accuracy comparable with that of the tests for intelligence. The temperamental tests now available were taught in laboratories, but so far their practical usefulness was limited.

MATERNITY HOMES AND COUNTY COUNCILS.

At a meeting of the Eastern District Committee of Stirling County Council, on March 10th, an important decision was reached in regard to support of maternity homes in general hospitals by the local authorities. The recommendation by the Public Health Subcommittee has been that the authorities in Stirlingshire should hold themselves responsible for the support of ten beds in each of two proposed maternity homes at the new infirmaries of Stirling and Falkirk. The maternity scheme is estimated to involve a capital contribution to the two infirmaries of £12,000 by the combining authorities. This, together with proposed venereal disease centres at the two infirmaries, would involve about four-fifths of a penny on the public health rate. It was agreed to give the District Committee's representative powers to approve of the adoption of such a scheme, subject to satisfactory arrangements being made with the Board of Health and with the board of directors of the two infirmaries.

GLASGOW ROYAL MATERNITY HOSPITAL.

At the annual meeting of Glasgow Royal Maternity and Women's Hospital, the Lord Provost, who presided, remarked that child welfare had come to be recognized as one of the most important obligations resting upon the community. If it were not for the facilities which

this hospital provided many of the children in the city would be born under conditions not only detrimental to their future welfare but hazardous to their lives. The community which looked after its children was the one which in the future would produce strong, robust, and vigorous manhood and womanhood to take up the responsibilities and burdens of their complex life. Dr. A. S. M. Macgregor, medical officer of health for Glasgow, made reference to the new laboratory of the hospital, which took a high place in the research work of the country; he believed that with adequate support it would become more and more useful not only to the city but to the nation.

AIR POLLUTION.

At a meeting of the Glasgow and West of Scotland Smoke Abatement League, Mr. W. Brownhill Smith said that domestic smoke was the greatest factor in polluting the air of Great Britain, and for this reason it was desired to extend the league to the whole of Scotland. In Glasgow a smokeless fuel as cheap as coal and as efficient as other fuels was available. He thought that the spread of information, together with some improvement in legislation to deal with cases of persistent neglect, would bring about the realization of a purification of the atmosphere, which seemed rather a hazy ideal some twenty years ago. It was decided to reorganize the league so as to form as many sections as possible in Scotland, and to establish an executive committee containing representatives of the various local authorities.

RECENT NOTIFICATION ORDERS IN SCOTLAND.

The Scottish Board of Health has renewed the Order requiring the notification of cases of infective jaundice. In view of the prevalence of small-pox in several districts of England, the magistrates and council of the city of Edinburgh on March 3rd ordered that the Infectious Disease (Notification) Act, 1889, shall apply within the city of Edinburgh so as to include chicken-pox. This temporary Order will cease to be in force on February 29th, 1928, or at such earlier date as may be fixed by the Scottish Board of Health. The Order came into operation on March 21st.

INFLUENZA IN SCOTLAND.

The Scottish Board of Health announces that the part of the country most seriously affected by influenza in the past week was the south-west. The two largest Ayrshire burghs, Kilmarnock and Ayr, both had relatively high death rates, and school absences at Ayr due to influenza have fallen only slightly in number. In Ayr county the disease was prevalent in many districts, except in the northern district. In Dumfriesshire the epidemic has been moving south-westwards and is now mainly confined to the south-west corner, while Kirkcudbright has experienced a sharp rise in prevalence within the past ten days, though in both counties the northern districts have suffered less than the others. Renfrewshire has cases in all parts of the county, though the numbers are not unduly large. Greenock shows an increase of cases over the previous week's figures. In Fife, Dunfermline burgh and district show an improvement, but Kirkcaldy burgh and district both had more cases. Motherwell and Wishaw has once more to report a heavier incidence. Elsewhere the epidemic is rapidly dying out. In Dundee the outbreak appears to be over, and in Aberdeen the prevalence of influenza is now normal for the time of the year. Equally encouraging reports have been received from other parts of the country, and there is ground for hoping that the end of the outbreak in Scotland is in sight.

Ireland.

ULSTER MEDICAL SOCIETY.

THE eighth meeting of the session was held in the Medical Institute, Belfast, on March 10th. The President (Dr. Nolan, Downpatrick), who was in the chair, presented Sir Thomas Houston with an illuminated vellum certificate of honorary fellowship of the society, and Sir Thomas expressed his thanks. Dr. E. P. Cumberbatch, director of the electrotherapeutic department of St. Bartholomew's Hospital, London, gave an address on recent advances of diathermy in medicine and surgery. He dealt with the treatment of chronic infections in gynaecological practice and with arthritis, both by general and local application, in surgical work and in medical conditions, hyperpiesia, sciatica, etc. Several questions were asked, and Dr. Cumberbatch gave answers. Professor R. J. Johnstone proposed a vote of thanks to Dr. Cumberbatch, which was seconded by Professor Fullerton and passed with applause.

CORONERS AMENDMENT ACT (FREE STATE).

The Coroners Amendment Act (1927), which has been recently passed by the Dail, contains many sections which are of interest to medical men practising in the Free State. Some important changes are made in the sections of the Coroners (Ireland) Act, 1846. The following sections are of special interest to medical practitioners:

Section 2.—(1) In any case (other than those provided for by Section 1 of this Act) in which the coroner is informed of the death within his district of a person who was not attended throughout his last illness by a duly qualified medical practitioner or that a medical certificate of the cause of death of any person is not procurable, he may inquire into the circumstances of the death of such person, and if he is unable to ascertain the cause of such death he may if he shall think fit hold an inquest for the purpose of ascertaining the cause of such death. The coroner may, at any time after he is informed of the death of any such person and pending any such inquiry, make an order for the burial of the body of any such person.

Section 2.—(2) It shall be the duty of the local superintendent or other officer of the Civic Guards, in case he becomes aware of the death within the district of a coroner of any person who was not attended throughout his last illness by a duly qualified medical practitioner, or in whose case a medical certificate of the cause of death is not procurable, to inform the coroner of such death.

Section 3.—(1). Subject to the provisions of this Section a coroner within whose district the dead body of a person is lying may, in lieu of summoning a jury in the manner required by Section 23 of the Coroners (Ireland) Act, 1846, for the purpose of inquiring into the death of that person, hold an inquest on the body without a jury.

Section 3.—(2) If it appears to the coroner either before he proceeds to hold an inquest or in the course of an inquest begun without a jury, that there is reason to suspect (*a*) that the deceased came by his death by murder, manslaughter, or infanticide; or (*b*) that the death occurred in prison or in such place or in such circumstances as to require an inquest under any Act other than the Coroners (Ireland) Act, 1846; or (*c*) that the death was caused by an accident, poisoning, or disease, notice of which is required to be given to a Government department or to any inspector or other officer of a Government department, under or in pursuance of any Act; or (*d*) that the death was caused by an accident arising out of the use of a vehicle in a street or public highway; or (*e*) that the death occurred in circumstances the continuance or possible recurrence of which is prejudicial to the health or safety of the public or any section of the public; he shall proceed in the manner required by the Coroners (Ireland) Act, 1846, and in any other case if it appears to him, either before he proceeds to hold an inquest or in the course of an inquest begun without a jury, that there is any reason for summoning a jury, he may proceed to summon a jury in the manner aforesaid.

Section 4.—In the case of an inquest held by a coroner with a jury, such jury shall consist of not less than six and not more than twelve persons.

Section 11.—(1) Where a coroner is informed that the dead body of a person is lying within his district and there is reasonable cause to suspect that the person has died a sudden death of which the cause is unknown, if the coroner is of opinion that a *post-mortem* examination may prove an inquest to be unnecessary, he may cause such examination to be made and the result to be reported to him, and for the purposes of the examination the coroner and any person authorized by him to conduct the examination shall have the like powers, authorities, and immunities as if the examination were an examination directed by the coroner at an inquest upon the body of the deceased.

Section 11.—(2) If as a result of such an examination as aforesaid the coroner is satisfied that an inquest is unnecessary, he shall send to the registrar of deaths whose duty it is to register the death a certificate under his hand stating the cause of death as disclosed by the report, and the registrar shall make an entry in the register accordingly.

Section 12.—(1) Without prejudice to the power of a coroner holding an inquest to direct a medical witness whom he may summon under Section 33 of the Coroners (Ireland) Act, 1846, to make a *post-mortem* examination of the body of the deceased, the coroner may, at any time after he has decided to hold an inquest, inform the Minister for Justice by writing under his hand that it is in his opinion desirable to have made (*a*) a *post-mortem* examination of the body of the deceased; or (*b*) a special examination by way of analysis, test, or otherwise of such parts or contents of the body or such other substances or things as ought, in the opinion of the coroner, to be submitted to analyses, tests, or other special examination with a view to ascertaining how the deceased came by his death; or to have both such examinations made, at the same time stating his reasons for such opinion;

and the Minister for Justice may thereupon appoint a legally qualified medical practitioner to make such *post-mortem* examination or special examination or may appoint any other person whom he considers to possess special qualifications for making such a special examination as aforesaid to make the special examination.

Section 12.—(3) The fee payable in respect of any such *post-mortem* or special examination shall be a sum not exceeding ten guineas, or such larger sum as the coroner shall with the approval of the Minister of Justice determine, and if the person making such *post-mortem* or special examination is summoned by the coroner as a witness to attend an inquest he shall be given such further allowance as the coroner with the approval of the Minister for Justice shall determine.

Section 13.—(1) The fees payable to a legally qualified medical practitioner who has made any *post-mortem* examination by the direction or at the request of a coroner, or who has attended an inquest in obedience to a summons of a coroner under the Coroners (Ireland) Act, 1846, or this Act, shall (save as in this Act otherwise expressly provided) be as follows: (*a*) for attending to give evidence at any inquest whereat no *post-mortem* examination has been made by the practitioner, not exceeding two guineas; (*b*) for making a *post-mortem* examination of the body of the deceased and reporting the result thereof to the coroner without attending to give evidence at an inquest, not exceeding three guineas; and (*c*) for making a *post-mortem* examination of the body of the deceased (including the making of a report, if any, of the result thereof to the coroner) and for attending to give evidence at an inquest on the body, not exceeding four guineas: Provided that no fee or remuneration shall be paid to a medical practitioner for the purpose of a *post-mortem* examination instituted without the previous direction or request of the coroner.

Section 13.—(2) In the case of any other witness attending to give evidence at an inquest, if the coroner shall certify that special circumstances exist he shall allow such sum for expenses as he shall consider reasonable, not exceeding in any one case the sum of five pounds.

England and Wales.

BIRMINGHAM HOSPITALS.

THE proposal to construct a new hospital centre at Edgbaston was discussed at the annual meeting of governors of the Birmingham General Hospital on March 16th. A site near the University has been offered by Messrs. Cadbury, and it is suggested that this should be shared by the General Hospital and the Queen's Hospital, which would eventually amalgamate. With this in view both hospitals have abandoned the idea of extending their present buildings, with the exception of a temporary ward which is to be built in the grounds of the Birmingham General Hospital in order to reduce the long waiting list of patients. A new building for the treatment of venereal diseases is also to be erected by this hospital, but the cost of this will be borne by the public health authorities concerned and not by the hospital. The annual report of the Birmingham General Hospital shows that the accumulated deficit on December 31st, 1926, was £23,435. The new contributory scheme which was originally suggested by this hospital, and which is now in the hands of the Hospitals Council of the city, will shortly come into operation, and will, it is hoped, be effective in placing all the Birmingham hospitals on a more satisfactory financial footing. This scheme aims at co-ordinating the various sources of hospital income. It is proposed to form a central managing committee, with subsidiary sections in the various wards of the city. The Hospital Saturday Fund will constitute the principal branch industrial contributors' scheme for employers and employees, and will pay to the central committee the total received, less amounts reserved for the special work of the Fund in connexion with such activities as the provision of convalescent home treatment and surgical aid. Contributions of 2d. weekly are invited from employees, and employers are asked to subscribe a sum equal to at least one-third of the total amount so obtained. The hospitals will still be open as before to patients too poor to contribute. Private individuals with limited incomes will be able to join a subdivision of the scheme, and so become eligible for free hospital treatment. It is hoped that each hospital will make a maintenance charge for other patients who are not contributors, but who could have afforded to pay at least 2d. a week. The new arrangement is not intended to interfere in any way with the systematic appeal by individual hospitals for subscriptions and donations from any sources not embraced by the scheme.

MEDICAL STUDENTS' VISIT TO BATH.

A party of medical students from Birmingham University, accompanied by Professor Douglas Stanley, professor of pharmacology and therapeutics, and other members of the staff, visited Bath on March 19th, to study the spa treatment of rheumatic and other diseases. After lunch the party assembled in the Pump Room, where Dr. A. Gordon Watson described the types of cases in which spa treatment is indicated. The bathing establishment was inspected under the guidance of the director of baths, Mr. John Hatton, and demonstrations were given of the various baths, douches, and other methods employed. The Royal Mineral Water Hospital was then visited, and cases were demonstrated by Drs. Rupert Waterhouse, R. G. Gordon, James Lindsay, H. Clulow Nixon, and Litt. After a short motor tour of the city to see the historic houses and the Georgian architecture of Bath, the Roman baths were visited. Before the party returned to Birmingham tea was served on the Roman Promenade.

HOSPITAL SATURDAY FUND.

A social gathering of the Hospital Saturday Fund was held in London at the Guildhall on March 16th. The Lord Mayor, president of the Fund, commented on the satisfactory progress during the fifty years of its existence, and made special reference to the valuable help it had given in maintaining the voluntary system. Its organization of the collection of subscriptions in workshops, factories, and offices had resulted in the people generally taking an increasingly keen interest in the work of the hospitals and recognizing their responsibility in the matters of maintenance and extension. The Earl of Malmesbury, chairman of the Fund, said that the income last year had amounted to £109,677, of which £30,577 had been received from patients, £4,127 from the General Post Office, £2,520 from the London, Midland, and Scottish Railway, and £1,623 from the London and North-Eastern Railway. Expansion of the work of the Fund had rendered it necessary to obtain new premises at a cost of £7,000. Nearly 47,000 letters had been issued for hospitals, convalescent homes, and sanatoriums, while 21,773 grants had been made for surgical appliances. He added that the attendance of the Lord Mayor at this social gathering which had replaced the annual dinners held in previous years was an illustration of the close connexion between the Mansion House and the Fund.

Correspondence.

SLEEP IN HOSPITAL.

SIR,—Many a true word is said in jest, and I should like therefore to draw the attention of your readers to an article in *Punch* (March 2nd, 1927), entitled "The Wash; or, Dawn in Hospital," by "A. P. H."

The art and science of nursing has become so nearly perfect that nobody bothers to inquire whether it could be improved. The question, however, of sleep is, I venture to think, a matter to which not nearly enough attention is given. If this matter is discussed with the nursing staff they always point out that the present routine of the hospital makes it imperative that washing should start in the very early hours of the morning. This enslavement to routine was carried out to such an extent in the war that I was obliged to ask my commanding officer to make it a rule that no washing should start before 6 a.m., except for therapeutic measures. At that time the number of nurses in the casualty clearing stations was very small, and when there was a particularly busy "strafe" on it was not an uncommon sight to see the tents lit up at 3 a.m. and washing commenced. We were told that the seriously wounded man was not washed, but his companions on either side who were slightly wounded and feeling full of joy at being away from the firing line used to have an animated conversation, so that sleep was impossible.

Many of your readers, like myself, have experienced the joy of a morning sleep after a restless night, and have also been rudely awakened in the early hours for ablutions.—I am, etc.,

MALCOLM DONALDSON.

London, W.1, March 21st.

THE THYROID AND MANGANESE TREATMENT IN ACUTE PNEUMONIA.

SIR,—The letter of your correspondent, Dr. R. O. Adamson in the JOURNAL of March 19th (p. 539), encourages me to offer an observation which appeared to me to be pertinent when I read the article of Dr. Roche to which he refers, wherein is advanced the therapeutic advantages of thyroid and manganese in acute pneumonia as advocated by Dr. Nott.

Lobar pneumonia, a self-limited disease, and one in which I venture to say one's prognostic deficiencies are only too often displayed, is, as Dr. Adamson suggests, an excellent opportunity to exhibit the apparent advantage of almost any treatment. During the war I enjoyed the exceptional opportunity of observing lobar pneumonia on a very large scale.[1] In two and a half years I saw 558 cases, the whole of the treatment of which I personally undertook or supervised. The mortality rate of the whole series was 10.9 per cent. I recollect, as bearing upon this subject, that at one time 53 consecutive cases, including several of the greatest severity, were treated without a death, and, if only one fatal result be included, this series numbered 94 consecutive cases. I think it would have been not merely reasonable, it would have been irresistible had any special or peculiar treatment been adopted, to have allocated to such treatment the credit of so exceptionally high a recovery rate. Yet at no time was any but symptomatic treatment employed.

Universal satisfaction will be expressed if Dr. Nott's treatment can prove to be a specific or at least a valuable adjuvant in the treatment of lobar pneumonia. But I can only agree with Dr. Adamson that the greatest care must be exercised in deducing the effects of any treatment.—I am, etc.,

London, W.1, March 19th. ADOLPHE ABRAHAMS.

THE USE OF TUBERCULIN.

SIR,—A perusal of the article on tuberculin in the BRITISH MEDICAL JOURNAL of February 19th (p. 340) led me to inquire what investigations into the use of this substance had been carried out in this country in recent years. I was surprised to find that there exists a committee, appointed, I think, in 1920, by the Medical Research Council, for the purpose of investigating the use of tuberculin in the diagnosis and treatment of human tuberculosis. It is true that I have failed to discover any reports made by this committee on human tuberculosis, though there are two reports on the use of tuberculin in cattle. But inasmuch as the three experts stated by you to have been appointed to investigate Dr. Camac Wilkinson's methods are members of the committee, something presumably has been done about the human variety of the disease during the seven years of the committee's existence. It seems a pity that some sort of report on the original reference to the committee is not yet available.

If, however, the committee finds its hands too full with the application of tuberculin to cattle, may I suggest that the National Association for the Prevention of Tuberculosis might usefully turn its attention to research? If I am correct in supposing that this association is meditating another campaign of what is called "propaganda," I venture to think that the funds it is setting out to collect might prove of greater value if devoted, say, to helping to establish an institute such as that suggested by Dr. Camac Wilkinson in a letter to the *Times* on March 15th. Propaganda is somewhat hackneyed; and, under present limited conditions of knowledge, has been carried about as far as the circumstances justify.—I am, etc.,

Felsted, March 21st. CHARLES BUTTAR.

THE PRACTICAL VALUE OF INSULIN.

SIR,—In the JOURNAL of March 19th (p. 530) you record the verdict of Professor Marcel Labbé that no case of true diabetes proves refractory to insulin. I should have agreed with him two months ago, but since then I have had under close observation a lad of 19 who is extraordinarily resistant to insulin. On a fixed diet of 50 grams carbohydrate, 80 grams protein, and 150 grams fat, 220 units of insulin a day failed to reduce the blood sugar to normal and to keep him sugar-free, and it required 400 units to reduce his blood sugar to normal. In my former experience such a diet has never required more than 60 to 70 units a day in the severest case of diabetes. Undoubtedly insulin had some effect on him, because when it was omitted he developed coma in a week, and was rescued by large doses of insulin. All the factors which are known to counteract insulin appear to be absent in his case. Another similar case is recorded by two careful workers, Mauriac and Aubertin (*Presse Médicale*, December 29th, 1926).

The above case will be reported more fully later, but in the meantime it may be of interest to know that cases extremely resistant to insulin do occur for no known reason.—I am, etc.,

THE MODERN TREATMENT OF HERNIA.

SIR,—Mr. M. Fitzmaurice-Kelly's interesting remarks on this subject (BRITISH MEDICAL JOURNAL, March 12th, p. 491) seem to call for a brief reply. I am very glad to know that he has already carried out the treatment of umbilical hernia by a combination of Mayo's and Gallie's technique just as I suggested in my paper. I feel sure that this is an advance in the surgery of hernia. Meanwhile I have learnt that even this method will not meet the requirements of every case. I have recently had occasion to operate on a very obese man for an enormous obstructed hernia in the region of the umbilicus. The hernia consisted of two peritoneal sacs—one small and one very large. The size of the resulting opening in the abdominal wall, combined with the fact that local anaesthesia does not give general muscular relaxation, made it impossible to obtain any real overlapping of aponeurosis. I therefore employed Gallie's ordinary technique as described for treating any ventral hernia, with a very satisfactory result.

Femoral hernia seen in profile.

With regard to Mr. Fitzmaurice-Kelly's theoretical objection to the operation which I have described for the larger femoral hernias, I am afraid that I have not succeeded in making quite clear the rationale of the procedure. The cure of the hernia is not dependent solely upon the integrity of the suture line between the aponeurotic flap and Cooper's ligament. The sutures are merely holding the flap in its new position and are not under any tension. The flap is forming a curtain *behind* the plane of the crural canal over an area larger than the actual opening, so that pressure from the abdomen will impinge on the flap as a whole and will not put a strain on the suture line in particular. The use of a fascial suture for fixing the flap is therefore a luxury rather than a necessity. I can only repeat that the method I described was used for the more difficult cases and has stood the test of time, some of the patients being men employed on heavy work. I may also point out that Mr. Fitzmaurice-Kelly's method does not overcome the only possible objection to the inguinal approach—namely, that a breach is made in the transversalis fascia in the floor of the inguinal canal, whereas the other method automatically deals with this at the same time.

I do not wish, however, to claim finality for this operation, as there are patients for whom it would be inadequate. Since publishing my paper I have operated on the largest femoral hernia that I have ever seen. The sac was eight inches in diameter, as shown in the accompanying profile view, and contained the greater part of the small

intestine. Gallie's full technique was employed under local anaesthesia. The lower edges of the internal oblique muscle and conjoint tendon were sutured along the crest of the pubes and this was oversewn with two further layers of fascial sutures, the inguinal ligament being incorporated in these layers. The patient, a woman of 66, was undisturbed by the operation, and the result appears to be excellent. Perhaps even Mr. Fitzmaurice-Kelly would have found it necessary to clear this sac from below as a preliminary!—I am, etc.,

London, W.1, March 12th. GEOFFREY KEYNES.

INFLUENCE OF MANURIAL CONDITIONS ON THE VITAMIN CONTENT OF GRAIN.

SIR,—The interesting and highly suggestive work on the above subject by Lieut.-Colonel McCarrison, referred to in your issue of March 19th (p. 530), raises a subject of far-reaching interest and medical importance. Your note emphasizes the probable value of the work in relation to dietary and disease in the East; it is advisable to keep in view the possibility that similar, although less pronounced, conditions of an allied nature may be operative in this country.

Within the past few years the opinion has been expressed by not a few thoughtful agriculturists that the widespread use of artificial chemical manures has exerted an unfavourable influence on the amount and value of the crops. The extension of the use of artificial manures in this country in the past twenty-five years has been remarkable, and there is some reason for thinking that this may have tended to exhaust the soil of some of the ingredients required for obtaining the maximum yield of grain of the best quality. My personal experience of this subject for some years past has forced me to share this opinion. McCarrison's work will be useful in drawing attention to the important problem of "deficiency" in relation to nutrition and disease in its widest biological aspects.—I am, etc.,

Edinburgh, March 21st. CHALMERS WATSON, M.D.

THE ORIGIN OF SYPHILIS.

SIR,—I have read with interest the article on "The Origin of Syphilis: New World or Old?" as published in your issue of December 25th, 1926 (p. 1235). This editorial inclines to the view that the American theory of origin of the disease appears to be weak from the evidences summarized. I am moved, therefore, to offer certain additional evidence supporting the "American theory." My colleague, Dr. Hugh J. Means, roentgenologist, has recently published an article entitled "A roentgenological study of the skeletal remains of the prehistoric mound builder Indians of Ohio" (*American Journal of Roentgenology and Radium Therapy*, vol. xii, No. 4, pp. 359-367, April, 1925), in which he shows (Plate I) illustrations of seven long bones which he considers exhibit evidence of syphilis in different stages of the disease. Dr. Means took advantage of the rich collection of skeletal remains of mound builders in the Ohio State Archeological and Historical Museum. "This investigation was undertaken to determine if an extinct race, apparently having had no contact with the later tribes and the white race, would show the same pathological conditions as are found to-day." He used the roentgenological method only, this being the first time this method has been used in connexion with this collection. Naturally, lesions causing general decalcification could not be demonstrated, so that malignancies, tuberculosis, and other afflictions where repair had not taken place are not found demonstrated. Among the bone diseases, Dr. Means claims:

> "There is no doubt that lues existed among the mound builders of Ohio. Definite gross and [illegible]ence of syphilis was found in three skeleton[illegible]ying degrees of involvement, from a simple [illegible] and roughening on the crest of the tibia, [illegible] bone invading the medullary canal with gumma formation. Two others were strongly suspicious and several more showed a possibility. Of the three positive cases, two occurred in one tribe and the third in another. The tibias were involved in all three individuals, in one case both, in another one, and in the more advanced case a tibia and ulna. Many more positive specimens would probably have been found if the skeletons had been in a less fragmentary condition."

The article takes up also evidences of Pott's disease, rickets, joint infections, osteitis deformans, coxa vara, hypertrophic arthritis, impacted third molar in ramus of mandible, and various fractures, as well as wounding agencies such as arrows and spears. Among conclusions: "It has been clearly proven that syphilis existed and was a fairly common disease."—I am, etc.,

EMERY R. HAYHURST, M.D., Ph.D.,
Professor of Hygiene, Ohio State University.

Columbus, March 7th.

SCIATICA.

SIR,—It is possible that some misapprehension may arise from perusal of the condensed account in the BRITISH MEDICAL JOURNAL for March 19th (p. 522) of Professor Vittorio Putti's lecture on a subject which, it has been truly observed, has hitherto attracted but little attention in England, although very closely studied by the French school of neurologists and osteologists. The word "névrodocite" was used more than ten years ago by Sicard (*Bull. et mém. soc. méd. des hôp. de Paris*, November 3rd, 1916; *Presse méd.*, January 7th, 1918) to express the alteration set up in nerve structures by their compression in bony, fibrous, and aponeurotic sheaths and canals. The word "funiculite" was used by the same observer so far back as 1913 (*Mouvement médical*, August, 1913) to indicate a neurodocitis due to compression of the united spinal roots in an intervertebral foramen.

An admirable account is given in André Léri's recently published work *Les affections de la colonne vertébrale*, embodying the work which the author and his colleagues have carried out during many years. Meynadier's *Thèse de Paris*, 1923 (*La Sacralisation Douloureuse*), gives what is perhaps the most complete bibliography of the subject that is easily accessible to English readers.—I am, etc.,

London, W.1, March 19th. F. G. CROOKSHANK.

INFLUENZA AND ALBUMINURIA OF PREGNANCY.

SIR,—Dr. Gutch (BRITISH MEDICAL JOURNAL, March 19th, p. 543) refers to a relationship between influenza and the albuminuria of pregnancy, amounting in his opinion not improbably to cause and effect. How explain it? The albuminuria is not due to the toxin of influenza, for "the pregnant woman only is affected in this way." Nor is it due to a too generous diet: Dr. Gutch has abandoned that view. Can the persistent cough explain it?

Two years ago, during a similar epidemic, a primigravida, 30 years of age, and seven months pregnant, developed a "terrible" cough and became pre-eclamptic; general oedema ensued, and the urine became scanty (8 ounces in twenty-four hours) and highly albuminous. The cough preceded the pre-eclampsia, and in my opinion caused it. But how?

In 1922, considering the proximate cause of the toxaemia of the pernicious vomiting of pregnancy,[1] the conception that vomiting is a pathological force arose and became defined. It was easy to see that the compressions of the liver, produced by the acts of vomiting, interfered with the blood flow through the liver; and that the kidneys were similarly affected by the same acts and in the same way, to the extent that they could not prevent albumin escaping. Thus, though greatly interested, I was not greatly surprised to find my patient, apparently quite well until she got influenza, become more or less rapidly oedematous with the rise and persistence of her cough, which she described as "terrible."

We have but to think of the enormous rise of pressure in the abdomen produced by cough, and to understand that with the abdomen distended by a pregnant uterus, the compression of the kidneys produced by cough must be greater than in those with flat abdomen, to see that the blood flow through the kidneys during each cough—especially in pregnancy—must be much impeded. And no great stretch of the imagination is necessary to allow the possibility that

[1] *Lancet*, 1922, i, 867.

a succession of such forces may produce albuminuria: thus, in athletes, albuminuria is produced by rowing a race (Collier). In the latter case, the kidneys become ischaemic through the violence and rapid repetition of the abdominal contractions (in which the diaphragm participates). In the case of a "terrible" and persistent cough, with the abdomen distended by pregnancy and the abdominal muscles in a state of greater tonic contraction than normal (as I have shown is the case in pregnancy),[2] the more marked implication of the kidneys in pregnancy and the relationship referred to by Dr. Gutch become of easy interpretation.—I am, etc.,

Rugby, March 20th. R. H. PARAMORE, F.R.C.S.Eng.

SIR,—Dr. John Gutch ends his letter on this subject in your issue of March 19th (p. 543) with the question, "and why it is that the pregnant woman only is affected in this way?" It has long been my experience that albuminuria, generally of slight degree, is so common in cases of influenza that it should be expected to be among the symptoms of any case of that infection. I have been surprised that this is not more generally recognized. —I am, etc.,

Manchester, March 20th. P. MCDOUGALL.

SPASTIC PARAPLEGIA.

SIR,—In the discussion on spastic paralysis reported in the JOURNAL of December 25th, 1926 (p. 1208), reference is made to the form of treatment introduced by me—that is, sympathetic ramisection (*Medical Journal of Australia*, January 26th, 1924).

In the first place, I would emphasize that ramisection was not based upon the hypothesis that the functions of movement and posture are performed by entirely different sets of muscle fibres, as stated by Mr. Bankart, but upon experimental observations made by me upon the effect of the removal of the sympathetic nerves from the left hind limbs of normal, spinal, and decerebrate goats. The film shown by Dr. Beattie illustrated the results of these experiments; and in reply to Dr. Adie and Dr. Walshe I have to state that the effects shown were constant not only in goats but in cats and rabbits also. In addition, Kuntz and Kerper were able to produce similar results in the dog (*American Journal of Physiology*, March, 1926).

In the second place, Mr. Bankart considers that the operations of sympathetic ramisection have now been given a fair trial, but his evidence is far from satisfactory. On examining his own statements the reasons for his failure are obvious. He has done the operation ten times; "in about one-half the cases" there was no appreciable effect upon muscle tone or upon the vascular condition of the limb. It should be obvious from this statement that the structures divided by Mr. Bankart were not sympathetic nerves, but this apparently escaped the notice of the neurological and physiological critics at the meeting at Nottingham, and at the meeting of the Royal Society of Medicine, reported in *Brain*, vol. 49, Part 1, p. 135. If this result was obtained by Mr. Bankart in "about one-half the cases," is it not fair to suggest an error in technique or an incomplete technique in the other half? Mr. Bankart says that his experience is similar to that of those who have tried the operation in America. He has apparently not seen the statement of Dr. von Lackum of the New York Orthopaedic Hospital (*Journal of Bone and Joint Surgery*), in which he says that the usefulness of grey "ramisectomy" in selected cases is, in his opinion, no longer in doubt, and, further, that a definite relief from spasticity will be noted and a marked increase in voluntary control will be gained

He is also not aware that ramisection, or a modification, is practised successfully at the Mayo Clinic, and that successful results have been obtained at the Toronto, San Francisco, and Los Angeles children's hospitals. From my own experience in Australia I am convinced that unsuccessful results can always be accounted for by the improper selection of cases, or by an error in technique.—I am, etc.,

March 2nd. N. D. ROYLE.

[2] *Proc. Roy. Soc. Med.*, Obstet. and Gyn. Sec., 1913, vi, 309.

OPTICIANS AND OPHTHALMIC BENEFIT.

SIR,—I am a whole-hearted opponent of all types of unqualified practitioners, and am in hearty agreement with the principle of Dr. Pocock's plea (p. 544) that societies should discontinue their practice of advising their members to go to qualified opticians. If any members of the general public ever peruse medical literature, however, I do not think they would be very favourably impressed with our cause if they found one of our leading medical journals publishing, in a prominent position, an isolated case in which a qualified optician showed an error of judgement in prescribing spectacles.

I once failed to diagnose, until after several days' delay, a case of ambulatory pneumonia; on another occasion I diagnosed a bronchiectatic cavity as an empyema, and aspirated—with disastrous results. I think these errors were far more serious than that made by the optician, and yet I should feel rather hurt if any colleague published these cases with an implied suggestion that patients should be advised not to consult men of my type! There is no evidence that the optician did not employ "reasonable care and skill," and if we are going to endeavour to damn the unqualified practitioner by promoting a principle that members of a profession must never make a mistake, I am afraid that we shall find ourselves "armed with a boomerang."—I am, etc.,

T. W. PRESTON, M.B., M.R.C.P.

London, S.E.19, March 19th.

"BIRTH CONTROL."

SIR,—The review in your issue of March 12th (p. 475) of the book *Medical Views on Birth Control* includes, in a composite summary of this very one-sided symposium, the opinion that, beyond a considerable number of cases in which there are definite medical indications for the prevention of conception, it is at least extremely doubtful whether a more general practice of this can be justified on any grounds. Surely, if contraception could be and were abolished, the birth rate would rise to over 30 per 1,000 per annum; and, to avoid a decline of our average duration of life, we should therefore require to maintain a natural increase of population of over 20 per 1,000 per annum, which is only possible in new countries. Taking the world as a whole, one may say that its food supply is increased so slowly that only a very small proportion of couples can get really sufficient food for themselves and more than three children.—I am, etc.,

London, S.W.7, March 12th. B. DUNLOP.

THE RHEUMATIC CHILD.

SIR,—Perhaps you will allow me to point out that the report on rheumatic fever about which you comment in the last issue of the BRITISH MEDICAL JOURNAL corroborates what I stated at the Conference on Cripples held in the British Medical Association's House last November, and published in the last issue of the *Cripples Journal*.

I pointed out that bad teeth, enlarged tonsils, damp houses, etc., may be associated with, but are not the cause of, rheumatic fever, whilst the one and only thing common to all these cases is malnutrition, whereby they get none of the lime-bearing foods such as milk, eggs, and cheese. In addition they aggravate this want of lime by partaking of acids like vinegar, sauces, pickles, and lemons.

Where two or three in a family fall a prey it is always found that their feeding habits differ from those who are not attacked, the latter liking and drinking milk.—I am, etc.,

Swansea, March 13th. G. ARBOUR STEPHENS.

Obituary.

JOHN BROWNLEE, M.D., D.Sc., F.R.F.P.S.,

Director of the Department of Statistics, Medical Research Council.

THE death, from bronchopneumonia, after little more than forty-eight hours' illness, of Dr. John Brownlee, which occurred on March 20th, will come as a great shock to his numerous friends. Dr. Brownlee had not enjoyed robust health for some years, but he was actively engaged in research work only a few days ago and apparently in his usual health and spirits.

John Brownlee was born in 1868, a son of the manse, and was educated in the University of Glasgow, where he had a brilliant career, securing first class honours in mathematics and natural philosophy in his arts course and commendation both for M.B. and M.D. degrees. He graduated M.A. in 1889, M.B. in 1897, M.D. in 1898, and D.Sc. in 1907. He was also a D.P.H. of Cambridge, and some years ago the Faculty of Physicians and Surgeons of Glasgow conferred upon him the distinction of election to the Fellowship without examination. After graduation and the usual resident posts, Brownlee spent two years as resident physician in the Belvidere and Kennedy Street Fever Hospitals, and then nine months as pupil-assistant to the late Dr. J. B. Russell in the Glasgow Health Office. This experience impressed him deeply, and Russell was for him one of those great men who, in Helmholtz's words, "alter one's whole scale of values." In 1899 Brownlee was appointed medical officer of health for Guernsey, and although he held the post only eighteen months this stay in an environment very different from that of a great industrial city also affected him deeply. In 1900 Brownlee returned to Glasgow as physician superintendent of the Belvidere Fever Hospital, and for the next fourteen years (he transferred from the Belvidere to the Ruchill Hospital in 1908) he was mainly engaged in the clinical and administrative work of a large hospital for infectious diseases. In this work he was conspicuously successful. Although not a fluent lecturer he was a wonderfully inspiring clinical teacher, and the writer of this notice well remembers the enthusiasm with which an old pupil of Brownlee, whom he messed with during the war, spoke of the Ruchill teaching. Brownlee found time, however, to apply his mathematical ability to medical and biological problems, and before his appointment by the Medical Research Council, in 1914, to be the first director of their statistical department, he had already published several important papers of a biometric character and won a reputation as a prominent exponent of the statistical method. From 1914 onwards Brownlee's professional interests were statistical, and a bibliography of his work since 1913 includes no fewer than forty-five titles; many of these papers, such as his memoir on the epidemiology of phthisis and his investigation of the periodicity of epidemics of measles, involved an immense amount of detailed analysis and are of permanent scientific value.

It is not possible, in a note written within a few hours of the loss of a great investigator, adequately to characterize the nature and value of his contribution to knowledge: it is hardly respectful even to try to do so. Perhaps it may be said that the real value of Brownlee's life work was not so much in any important specific addition to knowledge as in the general character, the *quality* of his work. This may at first seem a hard saying, for in the mere A B C of literary composition Brownlee was deficient. His literary style was not very attractive, and he had none of the power so conspicuous in, for instance, the writings of Mr. Udny Yule, of expressing a difficult mathematical argument in such a way that no attentive reader can fail to grasp it.

But any reader who cares to surmount the superficial difficulties of Brownlee's style is inevitably conscious of a certain philosophical breadth of treatment which he will seek in vain in the writings of most statistical epidemiologists. The memoir on the epidemiology of phthisis or the report on the mortalities of birth, infancy, and childhood well illustrates this quality. A reader may dissent from every particular proposition and yet feel that the author has placed him under a great obligation—has obliged him to look at the problems from a loftier standpoint. There is a great gulf between acuteness and sagacity. Of that acuteness which enables a man to solve neatly particular problems—the mental analogue of the precision with which a terrier nips rats—Brownlee had little; he was not acute in the narrow sense, but he was something more—he was sagacious. Of course, he had the defects of his qualities. People who did not know him intimately and sought guidance on some specific problem might be, and frequently were, exasperated by the way he would pass from topic to topic and leave the difficulty just where it was at first. But nobody who knew him intimately could fail to be struck by the immense range of his erudition or to be charmed by the simplicity of his character. It was easy to be vexed by his discursiveness when one wanted to have his opinion on a specific point, but one felt that, however discursive he might be, his influence on his associates was extraordinarily good, in that his ideal was that of a pure scholar. He was singularly free from personal jealousy or vulgar ambition, and if not in the formal sense a great teacher of statistical epidemiology, his writings and example have done, and will continue to do, great good. Many years ago Dr. Campbell Munro wrote: "Dr. Brownlee is a man of high intellectual endowments, of great breadth of view, of brilliant scientific attainments—a man who is certain to attain a high position in the public health speciality. He is a man of high moral purpose and elevation of character, and, with all his attainments, of singular modesty and simplicity." That might fairly stand for Brownlee's epitaph.

SIR HENRY CRAIK, BT., K.C.B., M.P.

THE death, on March 16th, of Sir Henry Craik removes from the House of Commons a member of a type not common in that assembly, but of great importance to its efficiency. He had sat in Parliament since 1906, when he was elected to represent the Universities of Glasgow and Aberdeen. After the redistribution in 1918 he became one of the three representatives of the four combined Scottish universities. He was born in 1846. He was educated at the High School at Glasgow, whence he went to Balliol as a scholar and exhibitioner. Immediately after taking his degree—which he did with honours in classics and history—he entered the Education Department, became a senior examiner in 1878, and secretary of the Scottish Education Department, Whitehall, in 1885. He retired in 1904. He was Conservative in politics, but kept an open mind, as becomes a university representative. Apart from politics he fully realized his responsibility to his constituents. He was always ready to study and, if he could approve, to support the views of the medical profession from his seat in Parliament, and to this Dr. Cox bears witness below. His chief contribution to literature was perhaps his book on *The State and Education*, a subject on which, by his long experience, he was well entitled to speak. But he also wrote *A Century of Scottish History* (1745-1843), with a discussion of the effects of the disruption in the later year. He edited also a series of volumes entitled *English Prose Selections*, writing introductions to four of the five volumes.

Dr. Cox, Medical Secretary of the British Medical Association, writes: Sir Henry Craik was a good friend of the medical profession and of our Association, and I have reason to know that he was pleased and proud when we made him an honorary member. I saw a good deal of him during the struggle over the original National Health Insurance Bill, which he cordially disliked. His instincts revolted against any interference with the freedom of any profession, for though he was an old civil servant and thus under the suspicion of favouring bureaucracy, he was a born individualist. On many later occasions I sought his help as a member of Parliament, and he was always ready to give it, even if it meant much trouble, for he took his duties as a university member very seriously. He will be a distinct loss to us and also to Parliament, for there are too few with his devotion to all that parliamentary institutions stand for. The service at St. Margaret's on March 19th, which I attended on behalf of our Council, was dignified and beautiful; representatives of Sir Henry's

family were surrounded by large numbers of members of Parliament and members of the public services, the universities, and the professions, all of which he had served with devotion and distinction. It was just, one felt, what he would have regarded as a fitting end to his work.

C. DA FANO, M.D.,

Reader in Histology, University of London (King's College).

DR. C. DA FANO, F.L.S., Reader in Histology at King's College, London, died with unexpected suddenness at his residence in London on March 14th, in his forty-eighth year. By his death medical science in this country loses one of the ablest exponents of histology.

Corrado Da Fano was the third son of Commendatore Alessandro Da Fano. He received his early training in histology in Golgi's institute of histology and general pathology at the University of Pavia, where he graduated M.D. in 1905, and later (1912) became Libero Docente in morbid anatomy. He obtained a travelling fellowship at Milan and worked in Ziehen's neurological clinic in the University of Berlin in 1908, and in the following year with Dr. Bashford at the Imperial Cancer Research Fund, London. After a period of work at Groningen he returned to Milan University as vice-director of the pathological institute. From 1915 to 1918 he served as captain in the Italian Army Medical Service on the Italian front. In 1918 he became lecturer in histology at King's College, London, and in 1922 was given the title of reader in histology in the University. Dr. Da Fano specialized in the histology of the central nervous system, and his advanced lectures attracted large audiences; the histological specimens by which they were illustrated formed a complete and noteworthy collection. His researches, published in a series of about sixty papers in various journals, were mainly concerned with the Golgi apparatus in cells and the special lesions of the nervous system in such affections as encephalitis lethargica. He had a very extensive knowledge of foreign languages, and he generously devoted a considerable portion of his time to acting as one of the editors of *Physiological Abstracts*. He married in 1915 Miss Dorothea Landau, and leaves a son and a daughter.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION TO THE COUNCIL.

MONDAY, March 21st, was the last day on which the names of candidates were to be received for the election of members of the Council which takes place on July 7th. Nine nominations have been forwarded to the Secretary by candidates seeking to fill the three vacancies occasioned by the retirement in rotation of Sir John Bland-Sutton, Bt., Sir Cuthbert Wallace (Vice-President), and Mr. W. Thelwall Thomas.

The candidates are: Sir Cuthbert Wallace, K.C.M.G., C.B. (St. Thomas's), Fellow 1893, Member 1891; Mr. W. Thelwall Thomas, M.B.E. (Liverpool), Fellow 1893, Member 1886; Mr. L. P. Gamgee (Birmingham), Fellow 1893, Member 1891; Mr. Herbert J. Paterson, C.B.E. (London Temperance Hospital), Fellow 1897, Member 1892; Mr. H. W. Carson (Prince of Wales's), Fellow 1899, Member 1895; Mr. J. P. Lockhart-Mummery (St. Mark's), Fellow 1900, Member 1899; Mr. Hugh Lett, C.B.E. (London), Fellow 1902, Member 1901; Sir Crisp English, K.C.M.G. (St. George's), Fellow 1903, Member 1900; Mr. C. C. Choyce, C.M.G., C.B.E. (University College Hospital), Fellow 1905, Member 1905.

The constitution of the Council since July, 1926, has been as follows:

President.—Sir Berkeley Moynihan, Bt., K.C.M.G., C.B., Council (1) 1912 (substitute), (2) 1919, Pres. 1926.

Vice-Presidents.—Sir Cuthbert S. Wallace, K.C.M.G., C.B., C. 1919; Mr. F. J. Steward, C. 1920.

Other Members of Council.—Sir Anthony A. Bowlby, Bt., K.C.B., K.C.M.G., K.C.V.O., C. (1) 1904, (2) 1912, (3) 1920, Pres. 1920, 1921, 1922; Sir John Bland-Sutton, Bt., C. (1) 1910, (2) 1918, Pres. 1923, 1924, 1925; Sir D'Arcy Power, K.B.E., C. (1) 1912, (2) 1920; Sir H. J. Waring, C. (1) 1913, (2) 1921; Sir John Lynn-Thomas, K.B.E., C.B., C.M.G., C. (1) 1918 (substitute), (2) 1925; Mr. Ernest W. Hey Groves, C. (1) 1918, (2), 1925; Mr. W. Thelwall Thomas, M.B.E., C. 1921; Mr. C. H. Fagge, C. 1921; Mr R. P. Rowlands, O.B.E., C. 1922; Sir James Berry C. 1923; Mr. J. Herbert Fisher, C. 1923; Mr. W. Sampson Handley, C. 1923; Mr. Percy Sargent, C.M.G., D.S.O., C. 1923; Mr. G. E. Gask, C.M.G., D.S.O., C. 1923; Mr. W. McAdam Eccles, C. (1) 1914, (2) 1924; Mr. Wilfred Trotter, C. 1924; Sir Charles Gordon-Watson, K.B.E., C.M.G., C. 1924; Mr. A. H. Burgess, C. 1925; Mr. V. Warren Low, C.B., C. (1) 1916 (substitute), (2) 1917, (3) 1926 (substitute); Mr. Victor Bonney, C. 1926 (substitute); Mr. G. Grey Turner, C. 1926.

The medical schools are represented as follows:

London:	
St. Bartholomew's	6
Guy's	3
St. Mary's	1
*Middlesex	3
St. Thomas's	3
University College	1
Royal Free	1
Total London	18
Provincial:	
Bristol	1
Cardiff	1
Leeds	1
Liverpool	1
Manchester	1
Newcastle-on Tyne	1
Total Provincial	6
Total Council	24

* One member retires and does not seek re-election.

UNIVERSITY OF OXFORD.

Proposed Research Fellowship in Medical Science.

A BEQUEST to the University was made by the late Gustave Isidore Schorstein, D.M., Christ Church, F.R.C.P., physician to the London Hospital and the Brompton Hospital for Diseases of the Chest, who died in 1905. The bequest was subject to two life interests, and these having matured by the termination of both life interests, a Decree has been promulgated in the University proposing to establish a research fellowship, to be called the Schorstein Research Fellowship in Medical Science. If the Decree, which was promulgated on March 15th, meets with the approval of congregation next month, it is probable that an election will be made during the Summer Term. The conditions under which it is proposed that the Fellowship shall be awarded have been published in the *Oxford University Gazette* of March 16th, 1927.

UNIVERSITY OF DURHAM.

AT the June convocation the honorary degree of D.C.L. will be conferred upon Sir James Berry, F.R.C.S., President of the Royal Society of Medicine and consulting surgeon to the Royal Free Hospital.

VICTORIA UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examinations indicated:

DIPLOMA IN PUBLIC HEALTH.—N. S. Craig, T. N. Fisher.
DIPLOMA IN PSYCHOLOGICAL MEDICINE (*Part I*).—Mary C. Luff.

UNIVERSITY OF ABERDEEN.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—G. J. Allan, A. W. Badenoch, J. Barclay, Catherine I. A. Craig, J. G. H. Davidson, R. G. Dingwall, P. T. J. Doss, A. D. Duff, G. A. P. Fraser, J. M. C. Gill, J. Leiper, J. W. Lobban, *N. J. Logie, *H. G. M'Pherson, C. P. Mann, G. N. Marr, *W. Marshall, J. R. Moir, J. H. Olby, *A. S. Paterson, Mary Riddoch, C. C. Ross, G. C. Walker, L. G. Walters.

* With distinction.

UNIVERSITY OF ST. ANDREWS.

THE University Court at its last meeting accepted with gratitude the gift of £100,000 to the University from an anonymous benefactor. Of this munificent donation £40,000 will be used for establishing a number of entrance scholarships of £100 a year each, confined to men students living in an official residence at St. Andrews; £29,000 will go towards the cost of the new hall of residence for men students; £8,000 will be used in improving the University chapel; and the balance, £23,000, remains at the disposal of the University Court.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

At the spring commencements in Hilary Term, held on March 19th, the following degrees in the Faculty of Medicine were conferred:

M.D.—R. E. Steen.
M.B., [illegible] G. J. Boorsen, G. D. Edwards, E. A. Ellis, [illegible] (*antea* Sherowitz), G. S. [illegible]

[illegible] Justice [illegible] Hume-Spry, [illegible] up, in 1918, [illegible] been asked by [illegible] ry had full [illegible] egligence and [illegible] conceded by Sir [illegible] Strode had be[illegible] verdict of the ju[illegible] pletely vindicated.

JUTH WALES.

[illegible], B.Ch., D.Sc., has been [illegible] College, in succession to [illegible] in the beginning of October.

Medico-Legal.

HUME-SPRY *v.* SMITH AND WATSON.

JURY STOP CASE: VERDICT FOR DEFENDANTS.

ON the fifteenth day of the hearing the special jury stopped the action in which Mr. F. Hume-Spry, now an official in the Probate Registry, claimed damages in the King's Bench Division from Dr. R. Percy Smith and Dr. A. H. Watson for their alleged negligence in certifying him as insane. Mr. Justice McCardie accordingly entered judgement for the defendant doctors with costs, the jury being exempted from further service for five years.

The previous proceedings in the case are reported in the issues of the BRITISH MEDICAL JOURNAL of March 12th (p. 495) and 19th (p. 547).

Evidence for Defence Continued.

Mrs. Hume-Spry, wife of the plaintiff, continuing her evidence in chief, said she was compelled by her husband to write unkind, or objectionable, letters to her mother-in-law. In 1921 her husband asked her to approach Dr. Woods to ask him to write to his mother about making provision for him. She did so, and Dr. Woods called to see her at her flat—"he told me that he was passing, having been to a nursing home, and that as he had not made any appointment he had thought that he would drop in and see what he could so. He said that he was in a great hurry, *and he asked me if I had had any dinner.* I said that I had not, and so we went to dinner at Pagani's Restaurant." She also dined with Dr. Woods at the Café Royal in January or February, 1921. Her husband suggested at the time that she should bring Dr. Woods into the flat and be discovered with him in a compromising position, but she told him he was mad and that she would have nothing to do with it. She thought it kinder to think him mad than a blackmailer—he had a sort of moral cancer. She never told her husband that Dr. Woods was in love with her and that she reciprocated it. While her husband was at Dolgelly she received a letter from him containing the words: "Don't waste your time being friendly with Woods. Get him compromised. . . . I suggest getting him to take you away for the week-end." She wrote in reply: "Cannot you realize that decent men do not sell their wives for cash?" He then wrote that he was coming to London to show her and Dr. Woods up, as no judge would believe Dr. Woods visited her flat merely to talk business. She telephoned to Dr. Woods that she wanted to see him but that she did not want to go to the hospital. They therefore met at Pagani's Restaurant, where she showed him her husband's letter, saying her husband had done the same sort of thing in 1918. The witness described the scene at Paddington Station and at her flat on her husband's return from Dolgelly. He found the letters he had written from Dolgelly and destroyed them. In March, 1921, when she and her mother were living in Marylebone, her husband came in late one night shouting: "Where is that man?" but the next morning he begged them not to tell the doctors. She never wrote a confession of misconduct with Dr. Woods. She had always opposed her husband's certification. There was no truth in the suggestion that she had misconducted herself with Dr. Stodart-Walker of the Ministry of Pensions. The witness then described the night of December 31st, 1922, when she woke up and found her husband had turned on the gas. Later, she told Dr. Prideaux and Dr. Forward, of the Ministry of Pensions, about this incident. On March 12th, 1923, her husband came to her flat at 11 p.m. and charged her with conspiring to get him certified. The conversation went on to 3 a.m. Then her husband put a carving knife to his throat, and she knocked it away, exclaiming, "If you do one more mad act I will have you certified." Later, the same night, she found her husband on one knee with the same knife to his own throat. The following day she informed Dr. Oliver (the medical superintendent at Latchmere) what had occurred, and she went to Latchmere and saw Dr. Percy Smith, one of the defendants, about her husband's condition. The day after that Dr. Oliver said her husband had not returned to the hospital, and asked her to sign an application for an urgency order. She did so, and later her husband called at her flat "oozing venom." She denied telling him that she had "got him in the hollow of her hand." When he left the flat she telephoned to Dr. Oliver and told him what had taken place. On March 17th she went to the Old Manor House, Salisbury, and saw Dr. Watson, the other defendant, and then signed the petition for the reception order.

Mr. Justice McCardie: It has been suggested that you were a party to a scheme to get your husband certified. Is there the slightest truth in that?—There was no conspiracy, or scheme, or plot. If I schemed at all I schemed to keep him out of the asylum.

Cross-examined, Mrs. Hume-Spry said there were worse things to be said about her husband than had already been said. He was a sexual pervert. He was always urging her to earn money for associating with men. His attitude was always that of an accommodating husband.

Sir Henry Maddocks: *If he had been scheming for your downfall, it is* very strange that the delusion that you had committed misconduct with Dr. Woods drove *him mad?—Yes, if he had not been mad before.* My sin was one of omission to get Dr. Woods compromised. If I had done that you wouldn't have had this case at all.

Continuing her evidence under cross-examination, Mrs. *Hume-Spry* said that when she and her husband were "hard up" in 1918 a young officer called upon her who said he had been asked by another man to visit the flat. Whilst he was there her husband appeared and asked the lieutenant "What the hell are you doing here with my wife?" The boy replied that her husband was the man who gave him her address as "a woman whom he might visit." Her husband admitted that night that what he had done was the act of a foul maniac. After her husband came out of the Old Manor House he told all her tradesmen at Westminster that she had been seduced by the whole of the Ministry of Pensions and half Harley Street. The witness added that everything that was foul and dishonourable appealed to her husband. In 1917 and 1918 it was quite clear that her husband wished her to make money by immorality.

Answering Mr. Justice McCardie, Mrs. Hume-Spry said she met Mr. Chetham-Strode, a barrister, when she was travelling to Belgium with her uncle, since dead, and there was not the slightest *foundation for the insinuation that she had misconducted herself* with Mr. Chetham-Strode.

Mr. Justice McCardie pointed out to Sir Henry Maddocks, counsel for the plaintiff, that he had said he had materials from which he could make reasonably definite charges against Dr. Woods, Mr. Chetham-Strode, and Dr. Stodart-Walker.

Sir Henry Maddocks: I say that I shall prove sufficient facts to show that the ordinary person would draw an inference that adultery had been committed. If I misled your lordship into thinking that I should prove actual adultery I never intended to do so. I meant that I should put before the jury such a state of circumstances that Mr. Hume-Spry had no delusion at all, but that he was entitled to draw the inference that adultery had been committed. Whether he was right or wrong is another matter.

Mrs. Hume-Spry, cross-examined on the contents of letters she received from Dr. Stodart-Walker, described them as "flippant rubbish." Her husband knew of the letters as they arrived; she kept them because there was nothing to hide. Witness said it was pure invention on the part of her husband that in 1922 she signed a confession of adultery with Dr. Woods. The confession her husband forced her to sign in 1918 was still with Mr. Francis, the solicitor.

On the instruction of the judge, Mr. Francis was sent for and, re-entering the witness-box, he produced the confession signed by Mrs. *Hume-Spry* in 1918. He explained that he had forgotten this confession when he gave his evidence. His recollection was that the plaintiff's solicitors asked him to produce a confession relating to Dr. Woods in 1922 which he did not remember having seen.

Continuing her evidence, Mrs. Hume-Spry described her interview with Dr. Percy Smith, one of the defendants. Dr. Smith put it to her quite straightly whether there had been any misconduct, and she replied that there had not been. He did not ask her whether she had ever given her husband cause for jealousy with any other man. At a later stage the witness said she saw her husband at the asylum on May 10th, 1923, and he begged her very hard to take him out. She saw no sign of his being cured: he was the same old Hume-Spry. She saw him again on September 5th, 1923, and was much impressed with the *improvement in him.* He thanked her for having had him certified because the shock of certification had made him realize the nature of his previous actions. In the course of answers to further questions by Sir Henry Maddocks, Mrs. Hume-Spry said she did not regard her husband's delusion about herself as proof of his insanity; *it was the mildest part of it.* At times he was dangerous, not only to himself, but to her and to the community generally. Asked if she considered him cured now, she said she would not go so far as to say that; she thought he was merely improved.

Mrs. Amelia Johnson, mother of the last witness, gave evidence of the bedroom incident—the alleged turning on of the gas by the plaintiff and the threats to his own and to his wife's lives with a carving knife. The plaintiff's temper, she said, was at times uncontrollable and he used filthy language. In the course of cross-examination she agreed that before strangers her son-in-law was always good-tempered. After she came to know that he wanted to blackmail Dr. Woods she continued to live with her daughter and the plaintiff. Her daughter would not leave the plaintiff—she had old-fashioned ideas about the duties of marriage.

Dr. James Cowan Woods, who was medical officer in charge of the special hospital for officers at Palace Green, Kensington, until it was closed in 1921, said that on the plaintiff's admission in 1920 he showed signs of general mental failure. Throughout the time the plaintiff was in the hospital he was a border-line case. The witness dined with Mrs. Hume-Spry at Pagani's Restaurant and at the Café Royal solely for the purpose of helping the plaintiff. Mrs. Hume-Spry showed him a letter from her husband from Dolgelly urging her to "get Woods compromised."

Mr. Neilson: Did you tell Mrs. Hume-Spry at any time that you were in love with her?—It is ridiculous.

Did she ever say that she reciprocated that feeling?—It is completely untrue.

The witness added that no patient was surreptitiously drugged at the hospital. He had no knowledge of the plaintiff's movements after 1921, except in March, 1923, when he was told that, in the opinion of the authorities at Latchmere Hospital, Ham Common, the plaintiff was dangerous to him. Later, the witness was told that the plaintiff had been certified. Asked by Mr. Neilson if people of unsound mind had delusions like this about sexual matters, Dr. Woods replied that they were the commonplaces of mental institutions.

Sir Henry Maddocks (cross-examining): Supposing a neurasthenic patient knew that a doctor had taken his wife out to dinner on three occasions, and had taken her back to the flat where she was living alone, do you think that he would be mad because he was jealous?—I cannot give you any answer to that.

That is what happened, is it not?—No; I met Mrs. Hume-Spry with her husband's full knowledge to discuss something at his repeated request.

On all the occasions on which we dined I was doing him a favour by devoting my time after my hospital work to communicating with his people with the object of *getting him a better regard from his mother.*

Is it not a delusion of neurasthenic patients that the doctors are paying attention to their wives?—*Not in any degree.*

Did you communicate with the Ministry of Pensions and tell them that one of your patients was accusing you of immorality with his wife, and that you would rather not keep him?—Within a few days he gave me a written apology. The whole thing was absolutely crazy.

Mr. E. D. Chetham-Strode, a barrister, in evidence, denied that *any misconduct had taken place between him and the plaintiff's* wife, and his lordship said the honour of the witness had been completely vindicated.

Dr. A. Stodart-Walker, in evidence, said he was assistant director of treatment and training at the Ministry of Pensions in 1922. He denied misconduct with the plaintiff's wife. "Mrs. Hume-Spry," he said, "is a woman whom it does not take long to know, and in a very little time we were in the midst of good-humoured laughter." The suggestion that there had been immoral relations was simply monstrous. In reply to Mr. Justice McCardie, who asked if there was the slightest ground for suggesting that he caused Mr. Hume-Spry's certification, the witness said he had nothing to do with it; he did not even know that the plaintiff had been certified. The head of Rotherfield Court, an officers' training centre near Henley, recommended that he should see Mrs. Hume-Spry. Her husband's welfare was a passion with her, and he was able to advise her whom to see at the Ministry of Pensions.

At the suggestion of the jury, the defence agreed to call Dr. Prideaux, Dr. Oliver, and Dr. Martin as their next witnesses.

Dr. J. F. E. Prideaux, Deputy Commissioner of Medical Services at the Ministry of Pensions, in his evidence, said that on December 11th, 1922, he saw the plaintiff at Rotherfield Court. His whole appearance—distracted, excitable, and agitated—was that of a very unstable person. From the reports the witness saw, and from observation, he concluded that it was unsuitable that the plaintiff should remain at Rotherfield Court, so he recommended his transference to Latchmere Hospital, which was then a "border-line" hospital. He was then of opinion that certification would probably have to take place later. On January 15th, 1923, the plaintiff called at the Ministry of Pensions and asked to be allowed to remain at Rotherfield Court. The witness then told him that he could not alter his decision, and the plaintiff was much upset. Mrs. Hume-Spry saw him (the witness) about the same time, and told him of the incident when her husband tried to poison her by turning on the gas in their bedroom. She was not in the least vindictive against her husband; on the contrary, she said that she did not want him certified. The story about the gas incident was consistent with Mr. Hume-Spry's condition at that time. The witness said he formed his opinion of the plaintiff's condition both on December 11th, 1922, and January 15th, 1923, quite irrespective of any accusations against Dr. Woods and the plaintiff's wife. At that time he knew nothing about the plaintiff's charges. While at Latchmere the plaintiff called several times on the witness at the Ministry, and told him that while at Palace Green Hospital Dr. Woods had drugged him so that he could go out with Mrs. Hume-Spry. The next time the plaintiff called he was almost in a state of mania. He burst into the office with his eyes bulging and was wildly excited, accusing the witness of being a friend of Dr. Woods and in league with him. The plaintiff also said he was going to thrash Dr. Woods, and then broke off the interview very abruptly and dashed out of the room. At the next interview the plaintiff was quiet and suspicious, and said that all the officers of the Ministry of Pensions were conspiring against him. At the last interview he was quiet, but said he would not remain at Latchmere, and that he would shoot Dr. Woods. The witness then came to the conclusion that he was definitely certifiable, whether his statements against Dr. Woods were true or not. He then telephoned to Dr. Woods and warned him, and also telephoned to Dr. Oliver at Latchmere Hospital, and Dr. Oliver agreed with the view he expressed. In April, 1923, the witness saw the plaintiff at the Old Manor House, Salisbury, and he thought that he had improved and might be on the way to recovery. He thought that Mrs. Hume-Spry was doing everything she could for her husband.

Dr. Prideaux, in the course of his cross-examination, was asked whether in January, 1923, he considered that the plaintiff ought to be certified in the public interest, and replied that he was not then prepared to make up his mind definitely. He agreed that if, in January, 1923, Mrs. Hume-Spry told her husband that the doctors at the Ministry of Pensions wanted to have him certified, that might have a tendency to disturb him, and if he were suffering from nerves that might tend to make him worse.

Dr. N. H. Oliver, a member of the Bar, and medical officer in charge of the officers' special hospital under the Ministry of Pensions at Latchmere, in his evidence said that within a few days of the plaintiff's admission to Latchmere he came to the conclusion that he was certifiably insane. The witness did not care about having him in his hospital, because he was very excitable and very suspicious, and had conceived a belief that there was a great plot against him *by everybody in the Ministry* of Pensions. The plaintiff even thought that the witness, as a doctor attached to the Ministry, was also concerned in it. The plaintiff asked him if he knew Dr. Woods, and when the witness replied that he did, the plaintiff said, "I thought you would." Later the witness heard reports that the plaintiff was threatening the other patients and the orderlies, and that the other patients objected to having him in the hospital. The day before he was certified the plaintiff went to London and stayed out all night without leave. On the following day the witness asked him what *he had been doing,* and he replied that he had spent a couple of hours on the previous night outside Dr. Woods's house. The witness asked, "What would you have done if you had seen him?" and the plaintiff replied, "I should have killed him. I intend to kill him." After that the witness had to take some step. At the witness's request Mrs. Hume-Spry came to the hospital, and he told her that her husband was too bad for his hospital. She did not wish him to be certified, and asked whether certification could not be postponed or avoided. The witness at that time formed the conclusion that if Mr. Hume-Spry was not dangerous then he would soon become so. He chose Dr. Percy Smith, the defendant, to see the plaintiff because of his eminence in the profession and of his independence of the Ministry, against whose doctors the plaintiff had made all sorts of charges. The witness took the steps for certification for the plaintiff's own benefit, as the witness thought he could not possibly get well in the circumstances in which he was. Compulsory discipline was the *only thing for him.* The day after Dr. Smith saw him (March 14th, 1923) the plaintiff left the hospital before breakfast, having told several people he did not intend to return. The witness looked upon him as being definitely and dangerously homicidal, and telephoned to Dr. Smith for an urgency order as soon as possible. It was a very anxious time.

Cross-examined, the witness said that what the plaintiff had said about his waiting outside Dr. Woods's house and intending to kill him impressed the witness more than anything else as to the urgency of certification. Mrs. Hume-Spry was opposed to certification, but at length she said to the witness: "If all you doctors think the same I am afraid that I shall have to give way." Asked by Sir Henry Maddocks what he would have certified the plaintiff for before March 13th, the witness answered: "Because *he was likely to be dangerous to others.*" He *added that the* plaintiff suffered *from insanity* of a delusional type. He believed that the whole Ministry of Pensions was in league against him. His reason was so distorted and warped that he was not always rational, and refused to be treated in any way, breaking all the rules of the hospital.

Mr. Justice McCardie: *Do you think that Dr. Smith was right in* certifying Mr. Hume-Spry on March 13th?—I think that he was absolutely right. I do not think that he could do anything else.

You yourself would have certified him on that date without hesitation? —Without hesitation.

Dr. S. E. Martin, the medical superintendent of the Old Manor House, Salisbury, said he received Mr. Hume-Spry into that asylum on March 15th, 1923. Two days later he saw Dr. Watson, the defendant, and told him that, in his view, Mr. Hume-Spry was a dangerous and possibly suicidal case. In his opinion it was quite proper to certify him, and he was not influenced by anyone in *forming that conclusion.*

Mr. Neilson: *Did you ever tell Mr. Hume-Spry that if he did not write* to Dr. Woods he would never get out of the asylum so long as he lived? —No.

It has been suggested that, thinking one thing, you expressed another because of your wife and child. Is there any truth in that?—No.

The witness added that Mr. Hume-Spry was kept in an observation ward, and the suggestion that he was put in a refractory ward was absolutely false. To say he was kept among raving lunatics was absolutely untrue. At one time the plaintiff maintained that his suspicions about Dr. Woods were without foundation. Mrs. Hume-Spry's attitude towards her husband was always very solicitous for his recovery. No pressure was ever brought to bear on the witness from any quarter to keep the plaintiff in the asylum, or to refuse him leave on parole. On August 28th the plaintiff wrote to the witness expressing appreciation of "your treatment of my case," and said that the Old Manor House had given him a perspective and enabled him to feel a much stronger man. On December 11th Mr. Hume-Spry was allowed on parole for a month to visit his sister. Although his condition was improved, he was not then fit to be discharged from institutional care. He did not return after the leave expired.

Cross-examined, Dr. Martin said the plaintiff was so manifestly insane when he was received by him that it would not have altered his opinion if he had known that the plaintiff had had grounds for believing his wife had misconducted herself with Dr. Woods.

As the witness was answering this question, the jury handed a note to Mr. Justice McCardie, who sent it to Sir Henry Maddocks.

Sir Henry Maddocks (after reading its contents): It is quite sufficient intimation for me. The jury for a long time have given careful attention to this matter. It has been gone into in great detail.

Mr. Justice McCardie: The jury say: "We are all of opinion that there must be a verdict for the defendants." I gather that after that you feel that it would be useless to proceed with the case.

Sir Henry Maddocks: I think that it would be wrong. The issue is one of fact for the jury. They have heard the evidence in great detail and they have acted on it. I have nothing to complain about.

Verdict for Defendants.

The jury then formally returned a verdict for the defendant doctors.

Mr. Neilson referred to the aspersions cast upon Mr. Chetham-Strode, Dr. Woods, Dr. Stodart-Walker, and Dr. Martin, and *expressed the hope* that it would be possible for his *lordship* and the jury to say that the characters of all these witnesses had been completely vindicated; also that, in view of what the last three witnesses who were called had said about Mrs. Hume-Spry's solicitude for her husband's welfare, she would be relieved of the baseless charges which had been made against her.

Mr. Justice McCardie said it was clear that the verdict of the jury had fully vindicated both the defendants from the charges of negligence and bad faith which were made against them. It was conceded by Sir Henry Maddocks that the honour of Mr. Chetham-Strode had been completely vindicated. It followed from the verdict of the jury that the honour of Dr. Woods had been completely vindicated. He also inferred that the honour of Dr.

Stodart-Walker had been vindicated, although his lordship had no doubt that the jury would like to express their regret at the careless and foolish letters he wrote. He must infer from the verdict of the jury—and he should hold it himself without the slightest hesitation—that there was not the faintest ground for the suggestion that there was a conspiracy by the officials and doctors of the Ministry of Pensions wrongfully to send the plaintiff to the asylum.

His lordship added: "I shall retain the documents in the custody of the court that the Director of Public Prosecutions may consider whether or not he shall take criminal proceedings against Mr. Hume-Spry for perjury, or such other offence as he may think fit."

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

BUSINESS in the House of Commons this week has included the second reading of the Cinematograph Films Bill, further discussion of the Navy Estimates, the second reading of the Consolidated Fund Bill, and certain Scottish business. In debating a London, Midland, and Scottish Railway Bill a number of members referred to the daily overcrowding of trains in East London and South Essex. The House of Lords has discussed the possibility of greater economy in national expenditure.

On March 22nd Dr. Fremantle presided over a meeting of the Conservative Health and Housing Committee, which discussed the Nursing Homes Bill, introduced by Mrs. Philipson. This bill is down for second reading on April 1st, as second order of the day. Its text was not available for the Committee, but it is expected to incorporate the recommendations of last session's Select Committee on Nursing Homes. The Health and Housing Committee was of opinion that the bill should be drafted so as to meet general approval and ease its passage into law this session, which is to be a short one. Emphasis on rigorous inspection of all nursing homes would probably be deprecated by those who wish to see the bill pass, but the need for registration of these homes is accepted.

A Mental Deficiency (No. 2) Bill has been introduced by Mr. Rhys Davies. It represents the Labour party policy on the question, and incidentally proposes to reconstitute the Board of Control.

The Mental Deficiency Bill.

Second Reading Carried.

In the House of Commons, on March 18th, Mr. Crompton Wood moved the second reading of the Mental Deficiency Bill. He said a mental disease which in its nature could be cured was dealt with in the Lunacy Acts, while the Mental Deficiency Act of 1913 dealt with those considered to suffer from arrested and incomplete mental development, and who, while likely to recover, required care, supervision, and control. The 1913 Act, though one of the most valuable social Acts ever passed, had the defect that only those mentally deficient "from birth" or "an early age" came within its scope. Those words, as generally defined by magistrates and medical practitioners, excluded several classes from the benefits of the Act. Encephalitis lethargica, and meningitis, and frequent epileptic fits might affect a person all through life, but unless these began at an early age the sufferers, though often rendered mentally deficient, could not come within the benefits of the Act. Another class suffered accidents causing damage to the brain. Cases in which the early history was lost were frequent. An instance had come before the Board of Control where a man, aged 36, was convicted forty times between 21 and 34 years of age, twenty times for indecent assaults. He had been imprisoned in all for five years between those ages. The cost in prosecution and imprisonment had been £1,000. No female was safe while he was at large, but his history before the age of 14 was unknown, and the magistrates could not make an order for his detention, as they held that the defect could not be proved from an early age. A bill introduced last session had been crowded out. The present bill had been so drawn up as to obviate any charge of interfering with the liberty of the subject; in its preparation the advice had been obtained of experts at the Ministry of Health and of the Board of Control, and with the assistance of the Association of Mental Welfare. The bill proposed the deletion from the Act of the words "from birth" and "from an early age," as recommended in the report of the Departmental Committee on Sexual Offences against Young Persons. A subsection defining mental deficiency, which was not in the Act, had been introduced. The bill of last session limited the period within which mental deficiency must appear to the ages of mental development, but in the present bill the age limit was put at 18 years. Many people wished the limit to be higher, but that age had been chosen to avoid opposition. From last year's provision that mental deficiency must be "induced after birth by disease, injury, or other cause," the words "or other cause" had been dropped. The original Act provided that a defective might be placed in an institution or under guardianship if "found neglected, abandoned, or without visible means of support, or cruelly treated." The bill provided that the good mother could apply to the magistrates for her defective child to be certified. It also provided that children incapable of receiving benefit in special schools or likely to be detrimental to others could be placed under supervision or sent to an institution. The bill would give education authorities power to recommend for supervision children who had been in special schools, in addition to their present power of certifying for guardianship or for committal to an institution. Mr. Wood remarked that he looked to supervision of mental defectives in their own homes as one of the great hopes of dealing with this problem. Of mentally deficient girls who had been allowed to go to their own homes under supervision of the London County Council during the first ten years of the Mental Deficiency Act, only 10 per cent. had children. Another clause in the new bill enabled a continuation order for a mental defective to be made by a doctor at the place where the boy was working. The boy would not be recertified by one medical practitioner alone. The case had to be investigated by three magistrates, with one or more women, and a medical practitioner added. A further clause made it the duty of local authorities to provide training and occupation for defectives who were at their own homes under supervision. Mr. Wood told the House how, at a recent visit to the Epsom Manor Institution for Mental Defectives, he had found a large number of young persons all working busily at trades. Their ages ranged from about 8 up to 25. In an adjoining mental hospital he found young sufferers from encephalitis lethargica among elderly people with no great provision made for their training. The children would benefit greatly by transfer to the special institution, and the bill was directed to empower such a transfer.

Sir Douglas Newton, in seconding, said that even under the extended provisions of the bill some mental defectives would not be covered. The medical profession had shown courage in the administration of the Act of 1913, but was not adequately covered by the present law. In 1925 there were 55,480 mental defectives in the country, or 1.46 per 1,000 of the population. Ascertainment tended to increase the figures. The argument that sterilization would prove a cheap alternative to segregation he did not think a sound one. Little expense would be saved to the community, and mental deficients nearly always led useless or harmful lives. Sterilization, if resorted to, would only result in 3 to 5 per cent. of those now in institutions receiving greater freedom. He urged that all cases of mental deficiency should be notified by local authorities before these cases reached the procreative age.

Colonel Wedgwood moved the rejection of the bill, and protested against the "detestable coercion" of taking into homes those defectives whose parents did not wish them to go. He referred to the case of a London labourer who had frequently been sent to prison for cutting off tresses of hair from girls on omnibuses. Under the bill that man, who ought to have visited a doctor, would receive a "life sentence" in an institution for mental defectives, though he would not be sent to one, because at present there was not adequate accommodation. He denied that statistics proved that persons called morally defective were sure to have mentally or morally defective children. The danger was that this bill would be used to prevent girls being on the streets. He would wager that most of the younger persons up to 25 who were in the homes for the mentally defective were women.

Mr. Crompton Wood intervened to say that most of them were boys.

Colonel Wedgwood said it was better to have an illegitimate birth rate which was diminishing than to hold over girls on the border-line of vice and immorality the fate of being enclosed in one of these institutions for life. He declared that the definitions in the bill were not of much importance; the expert would have his own way with the Act of Parliament, and would lock or unlock the door of the institution. He warned the House against building up a new worship of expert authority.

Mr. Rhys Davies said there were young persons in prison who should not be there, but were cases for sympathetic medical treatment. The same thing was true in the Borstal institutions. Greater powers should be given to the Ministry of Health to see that local authorities performed their duties under the Mental Deficiency Act. There was no place in the country where an adult suffering from "sleepy sickness" could be sent.

Mr. Chamberlain said he had received many letters from mental deficiency committees and organizations interested in mental welfare, all regretting that last year's bill had been dropped and urging its reintroduction in the same or a slightly modified form. He inclined to think that the definition of mental deficiency in the bill before the House was too narrow

and the limiting age of 18 too low. Defective children were happy in their institutions, and were treated with unvarying kindness, but were not suitable companions for non-defective children. The shortage of accommodation for these cases could be temporarily alleviated if other institutions now administered by boards of guardians could be handed over to the councils of counties or county boroughs. Meanwhile, let all be certified who ought to be. He did not think it necessary to provide special institutions for adult cases of encephalitis lethargica. He did not think the bill would require to be much amended, and hoped it would be carried.

Mr. Snell, as a member of the Royal Commission on Lunacy, thought that certification for mental deficiency should be the last resort. The first thing to do was to make sure that attention had been given to the physical health of the young person. Whatever good there might be in medical treatment for the mentally afflicted should be available for the adolescent. He was not satisfied that the bill sufficiently discriminated between temporary and permanent affliction. The House ought to have a healthy distrust of "medical omniscients." He declared that life in institutions for the mentally defective could not be happy. Mr. Charleton suggested that members and medical men did not understand the view of the working class woman on separation from her child. He had visited a number of mental hospitals and homes, and had noticed that in some cases the children cringed to the attendants. Attendants were far more eager to prevent the appearance of bruises on their patients than to treat them kindly. To a mother these institutions were asylums. His own boy had been mentally deficient from the age of 2, and had been kept at home. Though he (Mr. Charleton) had only been a fireman on the railway, all difficulties had been overcome by a mother's love.

Colonel James said that if Mr. Charleton had any charges to make against mental homes he should bring them definitely. To make insinuations in the House was most unjust. Many cases of mental deficiency were unwanted children, and at their homes got a cuff on the head rather than a mother's love. Many border-line cases suddenly "went off the deep end," and for them this bill was necessary. He hoped the bill would not be obstructed in Committee.

Mr. Smithers said one of the things of which they could be proudest in this country was the high standard of the medical profession. In the case of death or accident, or in the coroner's court, everyone seemed to accept the doctor's decision. Mr. March, in supporting the bill, paid a tribute to the way the London County Council had graded children in the various schools. He understood that there were 40,000 to 50,000 mentally defective children in the country, but only two or three schools for them. The local authorities should set about building institutions.

Sir George Hume gave details of what the London County Council was doing for the mentally defective, and said the Council was considering the provision of further accommodation, chiefly for criminal, intractable, and very immoral women. The bill introduced no new principle.

Major Crawfurd asked medical members of the House whether the ordinary medical practitioner was in fact duly qualified to give an opinion on cases of mental deficiency. Commander Williams thought that before passing the bill the House should be certain that there were means of training a staff adequate for the new institutions which would have to be provided. These modern institutions would be very costly. They might easily get an increased cost of £20,000,000.

Mr. Hardie, who had experience of schools for the mentally defective in Scotland, said the medical men of whom he had experience were not bigoted. He had cases of children, in the ordinary way looked on as hopeless, who had benefited wonderfully in the special schools. A boy who could not speak and could not add two and two was now a skilled designer in a carpet factory.

Dr. Vernon Davies said that no real opposition to the bill had been developed in the debate. Mental deficiency, or amentia, was absolutely distinct from dementia, and unfortunately cure could not be expected. Defectives could not be cured but might be improved. The bill did not mean that nearly all cases of mental deficiency must go to institutions. If they had to go, the liberty of the subject was efficiently guarded by the process which must be gone through. The whole idea of the Act of 1913 and of this amending bill was the benefit of the child. As to the cases of encephalitis in which arrested or incomplete development resulted, most people who were competent to judge agreed that these cases only occurred in adolescence, before the brain was completely developed. He protested that the medical men of the country were sometimes severely criticized from the Labour benches. Their knowledge was superior to that of a layman, and attention should be paid to them. Whether they were believed or not, they were doing the best for the patients. Mentally deficient children did not feel confinement in an institution as a normal child did. They were all one happy family, and when allowed to go home for a week or a fortnight had, he found, been delighted to return to their school, their games, and their playmates. In reply to the inquiry whether the medical men who were called in were duly qualified to give opinions on cases of mental deficiency, Dr. Davies answered "Yes, certainly." The first examination was by two medical men who had been approved by the Board. The second, at the end of twelve months or whatever the period might be, was by a local medical man who was perfectly competent to decide whether the child should continue under control or go free.

Dr. Fremantle said medical men were the last to declare at any moment that they were right in any decision. They might be empirics, as Mr. Charleton said they were, but they had information a little deeper and wider than that of other people, and they had to decide upon experience. Very often the restrictions provided greater freedom for mental defectives than they would otherwise have. Often the individual wished to stay when the officers of the institution suggested that he could go home. Mr. Charleton had suggested an intermediate type of institution where a patient could be kept for five days of the week and allowed home at week-ends. That system already existed in a number of institutions. There were 55,000 mental defectives in the country, and accommodation for only 5,000 in institutions, but a large number of institutions under the guardians were being set free by measures like the Widows' and Orphans' Pensions Act. In the interests of the mentally defective, of their parents, of the public, and of the future generation he hoped the bill would pass into law.

Mr. R. Morrison said he had spent many years in teaching mentally deficient children, and had seen the wonderful results achieved in the special schools. There were nearly always in these mentally defective persons some senses more acute than those of ordinary people. Sir Herbert Nield said that when on the Middlesex bench he had had border-line cases before him who could not be certified under the existing law. The bill would ensure that such persons received proper care instead of ordinary punishment, which, with or without hard labour, would tend to aggravate their condition.

The bill was read a second time without a division, and sent to a Standing Committee.

Midwives and Maternity Homes (Scotland).

The Midwives and Maternity Homes (Scotland) Bill was read a second time by the House of Commons on March 18th, without a division. In moving the second reading, Mr. Barclay Harvey said the bill was for the registration of midwives, to reduce the number of midwives who were not qualified, and for the registration and inspection of maternity homes. The infantile death rate was still high in Scotland. The efforts of certain local authorities had reduced it, but not the rate of maternal mortality, which was actually increasing in Scotland, being 6.2 per 1,000 births in the period 1915-22. A committee under Lord Salvesen had stated that the evidence it received was unanimous on the essential proposals of this bill. The births in Scotland were rather over 100,000 yearly, and 600 women died in maternity. The bill tightened up the provisions against the unregistered midwife, but made exception in cases in sparsely peopled districts or in emergencies which could not be foreseen. One clause entitled a midwife to be paid if she had been suspended from work owing to the possibility of her carrying infection through no fault of her own. The bill might be improved in committee.

Sir George Berry, in seconding, said the medical profession in Scotland entirely approved of the bill.

Mr. Maxton said the infant and maternal death rates in Scotland were disgraceful, and the heavy incidence was in the poor quarters of the big cities. In one ward of Glasgow the infantile death rate rose above 100 per 1,000 per annum; at the other end of the same city it was 32. City medical officers had proved that in the one- and two-roomed houses this death rate rose above the hundred, and in houses with five or more rooms it dropped to the twenties. The bill would have absolutely no effect. He did not see that the bill improved the inadequate arrangements made by the Act of 1915 for registration and training of midwives in Scotland. The Government had imposed the duty of doing this upon the Glasgow Maternity Hospital and similar institutions in Edinburgh, Aberdeen, and Dundee, but had made no allowance out of public funds.

Dr. Elliot said the bill was backed by members of all parties. All the points mentioned by Mr. Maxton could be threshed out in committee. The contributions from the child welfare centres of the Glasgow Maternity Hospital already amounted to £3,000 a year.

The bill, as already stated, was read a second time, and sent to a standing committee.

Tuberculosis.—During 1926, twenty-six officers and men were invalided from the Royal Air Force on account of pulmonary tuberculosis. Sir Samuel Hoare states that the figures for the last five years show a steady decrease in the numbers invalided for this cause. The number of men invalided from the Royal Navy for pulmonary tuberculosis in 1925 was 209, and in 1926, 179. No reliable figures exist on which to estimate the number of cattle in Great Britain which are affected with tuberculosis.

Boys in Mines.—A bill to prohibit the employment of boys under 16 at night below ground in coal mines was read a first time on March 16th, on the motion of Mr. Tinker, who stated that more than 25,000 boys below 16 years of age are working underground. He added that many mine managers considered it morally and economically unsound to work boys on the night shifts. Boys were prohibited from working on the surface between 9 p.m. and 5 a.m., but this prohibition had not been extended to boys below ground.

Opium in India.—Earl Winterton, on March 21st, informed Mr. Gardner that the number of licensed opium shops in British India in 1925-26 was 5,844. The latest figure of poppy cultivation in British India showed 114,198 acres in the year ending October, 1925; in addition there was a small area of 1,653 acres in the Punjab Hills.

Infant Welfare in Tropical Colonies.—On March 21st Mr. Amery informed Mr. H. Williams that measures were being taken in most tropical colonies on the lines that had been successful in reducing infant mortality in this country. In many of these colonies the results compared not unfavourably with what had been accomplished here. Infant welfare clinics had been established and women doctors, nurses, and health visitors, with experience in this branch of medical work, were being appointed in increasing numbers.

Gland Grafting.—Mr. Guinness, in reply to Sir H. Brittain, on March 21st, said he was aware of Dr. Voronoff's work on gland grafting, and he had arranged, with Dr. Voronoff's concurrence, for a small commission of scientific men to examine and report upon the experimental work on sheep which had been carried out at the Government breeding station in Algeria. The visit of the Commission had been postponed until October or November, when the grafted sheep would be available for examination.

Physical Condition of Recruits.—In 1926 1,028 men presented themselves for recruitment into the Royal Air Force. Of them, 258 were rejected on medical grounds, the principal causes of rejection being dental defects, deformity of feet, heart disease, poor physique, respiratory diseases, defective vision, and ear diseases. For the Royal Navy in 1926 an average of 5,100 candidates presented themselves each month, and the average rejected was 4,460, not all on medical grounds. The main medical causes for rejection were defects of vision, teeth, and hearing.

Poor Law Medical Relief.—Answering Sir Charles Oman, on March 22nd, the Minister of Health said he was aware of the recommendation of the Royal Commission on Poor Laws to the effect that medical relief should be made more readily accessible and of the evidence of a witness, speaking on behalf of the British Medical Association, to the effect that if doctors attended without an order the rule was that they did not get paid. He was not aware that at the present time any difficulty had arisen. He would be glad to consider any information which Sir C. Oman might have on the subject.

Infant Vaccination.—In an answer to Dr. Watts, Mr. Chamberlain said the total number of births registered in England and Wales during 1925 was 710,582, but the vaccination returns in regard to the children born in that year were not yet complete. Returns to hand related to a total of 708,500 children, and of these 37,728 died unvaccinated. Certificates of successful vaccination were furnished in respect of 313,450 children, and declarations of conscientious objection to vaccination in respect of 291,347 children. As regards the remaining 65,975 children, no such certificates or declarations were furnished. He had no information on the number of prosecutions.

Vaccination in Pensions Hospitals.—On March 21st Lieut.-Colonel Stanley informed Mr. R. Morrison that in consequence of the recent severe outbreak of small-pox in Monmouthshire, it was deemed necessary by the medical advisers of the Ministry of Pensions to take all possible steps both to protect the patients in the Ministry of Pensions Hospital at Chepstow and to obviate the closing of this important institution, which served the needs of pensioners in Monmouthshire and South Wales. Closure would have been the only possible course in the event of an outbreak of this disease in the hospital. Instructions had been issued to the medical superintendent advising him that in the case of any patient whom he considered not already adequately protected against small-pox, revaccination should be secured if he considered it necessary and medically practicable. If a patient refused or was not, on medical grounds, suitable for vaccination, the case was to be dealt with either by the temporary provision of alternative treatment, by isolation, or by other means, compatible with the welfare of the patient, which would obviate contact with other patients in the institution. These instructions had been carried out with careful regard to the well-being of all the patients concerned, and had so far been effective. Mr. Morrison asked whether any of the ex-service patients who objected to being vaccinated had since taken their discharge from the hospital. Lieut.-Colonel Stanley replied that three had left. Their time was practically up and they would have been leaving in any case.

Public-house Reform.—A Public-house Improvement Bill to amend the law relating to the sale of excisable liquors was presented in the House of Commons on March 16th by Dr. Fremantle, supported by Sir Herbert Nield and others, and was read a first time. It provides for the issue of an improved public-house certificate for premises intended to be used as a house of general public refreshment, including food and beverages other than excisable liquors.

Notes in Brief.

The Foreign Secretary understands that the publication of the League of Nations report dealing with the traffic in dangerous drugs is merely postponed temporarily pending revision.

The Commissioners of Customs and Excise are giving special consideration to applications for the delivery from bond of wine to be used in the manufacture of medicated wines.

The Minister of Education is informed that the London County Council has asked its inspectors to see, on visiting schools, that a sufficiency of towels is provided for the children. The Council is not aware of any complaints of insufficient supply of towels.

The Services.

HONORARY PHYSICIAN TO THE KING.

LIEUT.-COLONEL AND BREVET COLONEL J. A. HARTIGAN, C.M.G., D.S.O., R.A.M.C., has been appointed Honorary Physician to the King, vice Major-General O. L. Robinson, C.B., C.M.G., late R.A.M.C., who has retired.

ROYAL NAVY MEDICAL CLUB.

THE annual dinner of the Royal Navy Medical Club will take place at the Trocadero Restaurant, Piccadilly Circus, on Thursday, April 21st, at 7.30 for 8 p.m. Members who wish to be present are asked to inform the Honorary Secretary, Royal Navy Medical Club, Queen Anne's Chambers, Tothill Street, S.W.1, not later than seven clear days before that date.

NAVAL MEDICAL COMPASSIONATE FUND.

A MEETING of the subscribers of the Naval Medical Compassionate Fund will be held at 11.30 a.m. on April 21st at the Medical Department of the Navy, Queen Anne's Chambers, Tothill Street, Westminster, S.W.1, to elect six directors of the Fund.

DEATHS IN THE SERVICES.

Lieut.-Colonel William Richard Gore Hinds, R.A.M.C. (ret.), died on November 10th, 1926, aged 84. He was educated in the Queen's University, Ireland, where he graduated M.D. in 1863. Entering the army as assistant surgeon on March 31st, 1865, he became surgeon major, after twelve years' service, and retired with an honorary step as brigade surgeon in 1885. In the old regimental days he was with the Prince of Wales's Own West Yorkshire Regiment. He served in the Afghan war in 1878-80, when he took part in the defence of Kandahar, and received the medal.

Lieut.-Colonel Alexander Chalmers, I.M.S., has died of heart disease at Coimbatore, in the Madras Presidency, where he was civil surgeon, on October 27th. He was born at Ballarat, Victoria, on December 20th, 1872, and was educated at Aberdeen, where he graduated M.B. and Ch.B. in 1898. Subsequently he studied at Leipzig, and took the F.R.C.S.I. in 1909. He entered the I.M.S. as lieutenant on June 28th, 1900, and attained the rank of lieutenant-colonel on December 28th, 1919.

Surgeon Lieut.-Colonel William Patrick Smith, R.A.M.C. (ret.), died in London on January 3rd, aged 85. He was born on February 11th, 1841, and was educated in Dublin. He took the L.R.C.S.I. and L.K.Q.C.P. in 1862, and entered the army as assistant surgeon in September, 1863; he became surgeon major in April, 1876, and retired in October, 1888. As he had then over twenty years' service his title of rank was altered to surgeon lieutenant-colonel when the compound titles were introduced. In the old regimental days he served in the 35th Foot, now the 1st Battalion of the Royal Sussex Regiment.

Major Frank Stuart Tamplin, R.A.M.C., died at Chakrata on February 14th, aged 43. He was the only son of the late Dr. C. H. Tamplin, and was educated at St. George's Hospital, taking the M.R.C.S. and L.R.C.P. in 1910. After filling the post of house-surgeon, house-physician, and ophthalmic house-surgeon at St. George's Hospital, he entered the army as lieutenant on July 28th, 1911, and became major after twelve years' service.

Major Robert James McCormack, R.A.M.C. (ret.), died on January 2nd, aged 69. He was born on February 14th, 1857, and was educated at Belfast, taking the degrees of M.D. and M.Ch. in the Queen's University, Ireland, in 1881. He entered the army as surgeon on August 2nd, 1884, became surgeon major after twelve years' service, the title being altered to major in 1898; he retired in August, 1903. He served in the South African war in 1899-1902, when he was for some time principal medical officer at Durban, and afterwards took part in the relief of Ladysmith, being mentioned in dispatches (1901) and receiving the Queen's medal with a clasp, and the King's medal with two clasps. When on the retired list he was employed at Omagh from 1905 to 1916.

Medical News.

IN connexion with the Lister centenary celebrations in London a meeting will be held at King's College Hospital, Denmark Hill, on Monday, April 4th, at 3 p.m., when Sir Watson Cheyne, Bt., F.R.S., Sir Lenthal Cheatle, and seven others who served under Lord Lister will speak on his personality. Particulars of the reception of foreign delegates by the Prime Minister in the Great Hall of the British Medical Association, Tavistock Square, at 11.30 on Tuesday, April 5th, will be found at p. 579. Full details of the celebration in London are printed in a time-table published in the SUPPLEMENT (p. 104). The number of applications for tickets for the social evening of the Royal Society of Medicine on April 4th, when Sir StClair Thomson will give his recollections of Lister, has been so great that it has been found necessary to close the list and no further tickets can be issued.

DR. P. P. LAIDLAW, F.R.S., has revised the report of the Medical Research Council (No. 35) on the reaction of culture media, which was issued towards the end of 1919. Brief accounts are given of the principles involved in the determination of the hydrogen ion concentration, the preparation of standard solutions, and the adjustment of the reaction of media, with special reference to a colour comparator by the use of which greater accuracy is obtainable. The revised report (price 6d. net) is obtainable from H.M. Stationery Office or through any bookseller.

A MEETING in aid of the Society for the Provision of Birth Control Clinics will be held at 16, Grosvenor Street, W.1, on Wednesday, March 30th, at 5.30 p.m., under the chairmanship of Lord Dawson of Penn, G.C.V.O., M.D. Speakers: Mrs. Margaret Sanger (President of the American Birth Control League) and Mr. Harold Cox.

THE annual meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, Cavendish Square, W.C.1, on Friday, April 8th, at 5 p.m.

A COMBINED meeting of the Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions will be held at Oxford from April 7th to 9th. Professor Lyle Cummins will give an address on the bovine tubercle bacillus in immunization. A discussion of the defensive mechanism of the body against tuberculosis, from the physical and chemical, bacteriological, and immunological aspects, will be opened by Drs. Leonard Hill and John Freeman. Dr. A. G. Gibson will read a paper on the secondary infections in relation to the course of pulmonary tuberculosis, and Dr. A. D. Gardner will deal with the laboratory diagnosis. Dr. J Middleton Martin will detail gaps and flaws in the public health administration of tuberculosis. Visits will be arranged to the Wingfield Orthopaedic Hospital and the new Osler Pavilion. The annual meeting of the Tuberculosis Society will be held at Oxford on April 8th. Those who are not members of the two societies may attend as visitors, and further information may be obtained from the secretaries, Dr. F. J. C. Blackmore, the Tuberculosis Dispensary, Maxey Road, Plumstead, S.E.18, or Dr. J. R. Dingley, Darvell Hall Sanatorium, Robertsbridge. Those who wish to attend the meeting will be entertained at dinner, and those who wish to take advantage of this offer should notify the honorary secretaries not later than March 31st.

AT the meeting of the Harveian Society of London to be held in the Paddington Town Hall on Thursday, April 7th, at 8.30 p.m., a discussion on the treatment of Graves's disease will be opened by Mr. T. P. Dunhill, to be followed by Dr. C. M. Wilson and others.

PROFESSOR S. LYLE CUMMINS, C.B., C.M.G., will read a paper at the meeting of the North-Western Tuberculosis Society, to be held at the Public Health Laboratory, York Place, Oxford Road, Manchester, on Thursday, March 31st, at 3.15 p.m., on the bearing of recent laboratory research on clinical conceptions in tuberculosis. The meeting will be open to all medical practitioners, who are cordially invited.

DR. C. T. W. HIRSCH will lecture and give a demonstration for the Fellowship of Medicine on emergencies in anaesthetics at the Medical Society, 11, Chandos Street, W., on March 31st at 5 p.m. The same day, at 3 p.m., Mr. H. L. Attwater will give a clinical surgical demonstration at the All Saints' Hospital, Vauxhall Bridge Road, S.W. The lecture and demonstration are free to medical practitioners. From March 28th to April 9th the Queen's Hospital for Children will hold a special course. Also beginning on March 28th the Royal Eye Hospital staff will give a series of demonstrations during the afternoon for two weeks on diseases of the eye. The Fellowship of Medicine can arrange for practical courses in obstetrics and anaesthetics, and also for clinical assistantships in gynaecology; it provides also a general course of instruction at the associated hospitals. Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE course will begin at the Cancer Institute of the Faculty of Medicine in Paris on May 16th, and will include lectures and a series of practical and clinical demonstrations on the nature, diagnosis, and treatment of malignant disease. Further details may be obtained from the Secretary of the Scientific Section of the Faculté de Médecine de Paris, 21, Rue de l'École de Médecine, Paris (VIe).

A NATIONAL Conference on Maternity and Infant Welfare will be held in the Great Hall of the British Medical Association, Tavistock Square, on July 5th, 6th, and 7th, under the presidency of the Minister of Health. The subjects to be discussed include atmospheric pollution in relation to maternity and child welfare, the provision of efficient sick nursing in the homes of children under school age, respiratory disease in relation to infant mortality, the provision of adequate accommodation for childbirth, the development of dental clinics for mothers and children under 5, the incidence of venereal disease in ante-natal and post-natal clinics, the results of artificial light treatment of children under school age, and the pasteurization of milk in relation to surgical tuberculosis. Lectures and film displays will be given in the evenings, and the travelling exhibition of the Central Council for Infant and Child Welfare will be on view each day. Visits will be paid to a number of maternity and child welfare institutions in London. It is stated that the Minister of Health will sanction the payment of the reasonable expenses of one delegate from any local authority or board of guardians, but that no grant under the Maternity and Child Welfare Regulations will be payable in respect of such expenditure.

IN connexion with the forthcoming Whitsuntide Congress at Ghent of the Royal Institute of Public Health there will be a section devoted to industrial hygiene, of which Lord Leverhulme is the president. Special discussions are to be held on industrial cancer, rheumatism, and temperature and humidity in industrial health. Medical practitioners wishing to participate in these discussions are invited to communicate with Dr. A. Vernon Davies, O.B.E., M.P., House of Commons, London, S.W.1.

COLONEL ROBERT J. BLACKHAM, C.B., C.M.G., late Honorary Surgeon to the Viceroy of India, has been appointed Commandant of the City of London Police Reserve.

IN accordance with the age limit of 68 fixed by the new federal constitution in Germany several professors in the medical faculties have recently resigned, including the physiologist Rubner, the internists F. Krauss and Goldscheider, and the medical jurist Strassmann.

THE Board of the London School of Hygiene and Tropical Medicine has combined the existing departments of entomology, helminthology, and protozoology in a division of medical zoology, under the directorship of Professor Leiper, F.R.S.

IT is announced that the Civil Service bonus for the six months dating from March 1st, 1927, will be calculated on the basis of a cost-of-living figure of 80 as against the figure of 70 for the past six months. This is a return to the level of March 1st, 1925.

THE late Dr. F. O. Stedman, formerly of Hong-Kong, who died at Weybridge in February last, has left estate of the gross value of £107,195 with net personality £101,000. He has bequeathed £500 to the Weybridge Cottage Hospital.

PROFESSOR EHLERS of Copenhagen has been made a Grand Officer of the Legion of Honour, and Professor David Giordano, senior surgeon to the Civil Hospital at Venice, has been nominated Grand Officer of the Crown of Belgium.

A DENIAL of the allegation that syphilis is caused by vaccination has been issued by the three Surgeon-Generals of the United States Army, Navy, and Public Health Service. It is stated that though 5,650,000 individuals have been vaccinated since 1917 by the Army and Navy, in no single instance has syphilis developed as a result, and none of the 2,918,000 vaccinated by the Public Health Service have contracted syphilis thereby. A similar immunity followed the vaccination of over 2,000,000 persons by local health authorities. In the United States the calf vaccine used is prepared only in licensed establishments under special regulations, which provide for repeated inspections of the laboratories and for proper safeguards as regards filling and labelling the tubes.

VACANCIES for two medical officers in the Sudan Medical Service are announced in our advertisement columns. The candidates, who must be single and under 30 years of age, must have held a resident appointment in a large general hospital. The pay commences at £E.720 a year, rising to £E.1,200 after thirteen years' service.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

CHRONIC URTICARIA.

"A. F." writes: "Pruritus" should try small doses of thyroid, watching carefully the pulse. I had a similar case that went on for over a year, in spite of all treatment, including dieting, calcium, collosol manganese, etc. I noticed a very minor degree of hypothyroidism, and gave thyroid and iodine, with a very satisfactory result.

MORBID SHYNESS IN A CHILD.

"K. H. G." writes: In reply to my letter in the JOURNAL of February 26th (p. 410) asking for suggestions as to the treatment of a case of morbid shyness in a child of 8, Dr. R. MacD. Ladell (March 19th, p. 551) states that to treat the cause of the shyness one must be aware of what is passing in the child's mind, and this can only be done by a process of psychological analysis. This hardly seems practicable to me in a case of this nature, where the presence of a stranger (even a strange girl of about her own age) causes her to run away, hiding her face with her hands—all entreaties being unavailing.

INCOME TAX.

Wife's Income: Letting of Unfurnished Rooms.

"OVERTAXED" inquires whether his wife can claim repayment in respect of her separate income of £40, and whether he is liable to tax on receipts from letting unfurnished a portion of his own house.

*** (1) No claim can be made in respect of the wife's income; the income of husband and wife are aggregated, and presumably all personal allowances have been made from the husband's income. (2) Any liability to tax on the receipts from letting is covered by the assessment under Schedule A—sometimes referred to as the Property Tax—and the item need not be separately declared.

Income from Irish Free State.

"H. S.," who resides in England, understood that double taxation was done away with in 1926, but is informed that English tax will still have to be paid on the Irish property, although the income has already borne Irish tax.

*** The change made was in the direction of simplification, and it was certainly understood at the time that it would reduce the number of cases where both payments would have to be made. Assuming that the year in question is 1926–27, we suggest that "H. S." should ask the local collector to arrange for the English assessment to remain in abeyance until the Irish tax can be reclaimed and set against the English liability. A call at the office of the inspector of taxes might prove helpful.

LETTERS, NOTES, ETC.

THE NEWSPAPER REPORTER.

THE average newspaper reporter seems to be, in the strict etymological sense, incorrigible. In a report of an address to the Hammersmith Rotary Club a few days ago Sir Squire Sprigge was made to confuse the General Medical Council—a statutory body appointed in accordance with Acts of Parliament, and possessing, among other functions, certain penal powers with regard to registered members of the profession—with the Council of the British Medical Association—the executive of a purely voluntary body. He was also made to say that Britain was the only country where a man could not practise as a doctor unless he was on the *Register*. Of course, Sir Squire Sprigge never made any of these blunders, but they were passed by the editor of a news agency and published by a great London daily newspaper. If a reporter were to make blunders on the same scale about the Lincolnshire Handicap or Grand National, what would happen to him?

COINCIDENT HERPES AND VARICELLA.

TWO cases of the simultaneous occurrence of varicella and herpes zoster were reported in our columns on March 5th (p. 423), and an account of an another case is published by Dr. R. L. Thorold Grant in the *Medical Journal of Australia* for February 5th, 1927. A woman, aged 37, had had Hodgkin's disease for four years; it was kept in check by deep *x*-ray therapy, and signs of enlarging mediastinal glands had recently been treated in this way; shortly after the last irradiation a severe attack of herpes zoster along the course of the left sixth thoracic nerve began and was followed a few days later by an equally severe attack of herpes zoster along the course of the right seventh thoracic nerve; eventually the complete encirclement of the patient with a ring of herpes. At the height of the eruption she developed a profuse generalized varicella rash on the chest, back, abdomen, and scalp, with scattered vesicles on the extremities and face, and within the mouth. There was at that time in Adelaide a mild epidemic of chicken-pox, which the patient had not had in childhood.

ENLARGED PROSTATE APPARENTLY CURED BY COLD WATER APPLICATIONS.

DR. J. CORBET FLETCHER (London) describes a case of reduction in size of an enlarged prostate following continued applications of cold water to the perineum. He states that four years ago a man, aged 58, consulted him for difficult and painful micturition, the urine being tinged with blood. In addition to a large prostate, a ring of external piles was present. For the bladder condition a mixture of potassium bicarbonate, hyoscyamus, and camphor water was prescribed, and the patient was advised to bathe the piles with cold water twice a day. Last month Dr. Fletcher re-examined him and found that the piles had disappeared and that the prostate had returned to the normal size and gave no trouble. The patient has now no bladder difficulty of any kind, and attributes the cure to the cold water applications. Dr. Fletcher adds that in a long medical career he has never encountered another case of enlarged prostate cured except by operation.

CO POISONING.

DR. CHARLES W. CRAWSHAW (Ramsbottom) writes: In your issue of March 5th last Dr. Douglas J. A. Kerr, referring to the extreme toxicity of carbon monoxide, states that an individual breathing an atmosphere containing 1 per cent. of carbon monoxide will have 50 per cent. of carbon monoxide in his blood in fifteen or sixteen minutes. Thirteen years ago I received an urgent message to attend a fireman who had been taken suddenly ill whilst on his way to a fire. On my arrival at the warehouse to which he had been taken I found that he was dead. I was particularly impressed with the bright red colour of his lips and the pink tint of his skin. His fellow firemen informed me that he was apparently well when he took his accustomed place on the engine, but collapsed when about half a mile of the journey had been covered. The fire engine was a horse-drawn vehicle with a low chimney, and the deceased, whose seat was immediately behind the chimney, would be in a likely position to inhale the fumes. The *post-mortem* examination revealed no obvious cause of death, and at the inquest I stated, as my opinion, that death was due to carbon monoxide poisoning, basing this opinion on the rapidity of death and the *post-mortem* colour of the mucous membranes and skin. The interesting feature in the case was the fact that it was possible to inhale a poisonous dose of carbon monoxide in such circumstances — on a moving vehicle in the open air.

A DISCLAIMER.

DR. ALEXANDER BRYCE (Birmingham) desires to disclaim all responsibility in connexion with a paragraph—misleading in substance—which appeared in the London *Daily Mail* of March 19th, referring to his article on "Anaphylaxis and ultra-violet light treatment" in the BRITISH MEDICAL JOURNAL for that date.

VISUAL IMAGERY: CORRECTION.

PROFESSOR T. H. PEAR asks us to correct a technical term in the report of his lecture on visual imagery published in the JOURNAL of March 12th (p. 471). In line 13 of column 2 for "ideatic" read "eidetic."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 39, 40, 41, 44, and 45, of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *103*.

A Clinical Address
ON
SOME VARIETIES OF HEADACHE.*

BY
LORD DAWSON OF PENN, G.C.V.O., K.C.B.,
M.D., F.R.C.P.

In the address I have the honour to present to you to-night I propose to deal with certain forms of headache which, however distressing, are compatible with, and often characterize, an active life. That is to say, I am excluding from my purview the headache, on the one hand, of structural diseases such as nephritis and intracranial tumour, and, on the other hand, the headache which is a feature of certain infections.

Headache is a term of variable significance—the variability in its intensity suggests the best classification of pain with which I am acquainted—namely, (1) pain which one can forget, (2) pain which one cannot forget, and (3) pain which makes one forget everything else. Moreover, its character varies: it may be described as pain; as unbearable pressure; as throbbing, splitting; as a band of *compression*.

The origin of headache must lie in structures which are sensitive to pain. The dura mater and its extensions like the falx cerebri and the tentorium and the anterior two-thirds of the scalp are supplied by the trigeminal nerves. The posterior region of the scalp and the dura of the posterior fossa are supplied by sensory fibres coming from the upper cervical segments. Tension or stretching of the dura would, as in the case of the parietal peritoneum, produce pain, whereas the brain, like the intestines, is insensitive.

How is this tension set up? The skull is a rigid container which closely fits the brain, and the spare space for the expansion of the latter is strictly limited. If for any reason the spare space is inadequate for the brain expansion, it is suggested that tension results and pain may follow, referred to within the cranium, and, it may be, the scalp. The expansion may be produced by increasing the arterial inflow or retarding the venous outflow or by a swelling of the brain substance (an oedema). Sudden exertion will produce arterial flushing, and lowering the head below the level of the body venous engorgement.

By others it is thought that vasomotor instability is the cause of headache attacks—that is, spasm of cerebral arteries followed by dilatation. Widespread and obvious vasomotor disturbance occurs in many cases of headache; *contraction and dilatation* of the retinal arteries have been observed during attacks of migraine. Moreover, the pinched features, the cold nose and extremities observed before an attack, followed by polyuria as the attack eases, are suggestive of a vasomotor causal factor. Spasm of arteries offers some sort of explanation of localization of headache to one side of the head, or to the frontal, temporal, or occipital regions, and such phenomena as hemianopia and rarer manifestations of migraine like aphasia and paresis. The difficulty is that there is experimental evidence that the cerebral arteries are unresponsive to vaso-constrictor and vaso-dilator impulses.

We must admit that the precise mode of production of headache baffles us. Any valid explanation must account for its occasional rapid appearance and disappearance. I may exemplify this by the quick onset of headache from sudden anxiety and the rapid disappearance after evacuation of the colon.

In one's doubts as to pathogenesis there is a tendency to fall back on the endocrine system. There is no direct evidence of the latter's share in this problem, unless perhaps in relation to pituitary headache. The ductless glands do, however, seem to be a liaison between bodily and mental functions, and with headache this interaction is frequently seen. It is possible that the mechanism of headache may be set in motion by chemical rather than nervous stimuli.

The incidence of headache is variable. On the one hand there is the man of middle or old age who has never had a headache, and on the other hand the subject who seldom goes two or three days without one. Between these two extremes there is every variation. And this leads to the reflection that headache cannot be taken only as a measure of functional defect, but also as a feature of the patient's make-up or individuality; it is his reaction to environment. The same chain of events will lead to severe headache in one patient, slight headache in another, and in yet another no headache at all. Headache is like hyperpiesis: both are different varieties of responsiveness, of inborn trends which will develop or no according to the career of the possessor.

Given the innate nervous state with its characteristic impressionability and, with this, a responsible anxious life or such accessory factors as eye-strain, digestive or metabolic faults, and migraine will be your portion: you are a victim of physiological predestination.

If we call to mind cases of headache which fall into my category—namely, those which are compatible with and often characterize an active life—either they accord with the classic descriptions of migraine, or are associated with disorders of the alimentary tract, or are the result of physical or mental exhaustion, of anxiety states, or other psychical conditions.

I seek to show that there is a close interrelationship between apparently different clinical pictures.

The conception of migraine has been clouded by the dramatic features of its classic form of attack or by over-emphasis of one or other of its manifestations. In one person there is the characteristic hemicrania, with or without visual phenomena; in another the headache is bilateral and is associated with nausea and vomiting; in yet another there is no headache and the manifestations are abdominal. The form may vary in the lifetime of one individual and in members of the same family. The cyclical *vomiting of childhood* may give place in the twenties to the classic hemicrania with its aurae, and this in turn may give place in middle life to recurring general headache associated with gastro-intestinal disturbance.

The clinical pictures are equally variable and suggestive. There is the disciplined man with a high-strung nervous system who has had a heavy week's work and perhaps is congratulating himself how well he has stood it. He plays a game of golf on Sunday. He may then plume himself on the fact that he is as young as ever and play a second round. He then eats freely. Then comes the downfall—migraine. What happens? He is a man in whom the burden of fatigue falls on his plain muscular tissue. As the week advanced his stomach and intestine lost tone, and the functional capacity of digestion and metabolism deteriorated. The physical fatigue of the golf on the top of the week's duties lowered his blood pressure and put his digestion out of business. Here the sequence of events was: exhaustion—*failure of digestion*—toxaemia—headache. One round of golf followed by a light meal and recumbency would have done him good.

In very marked cases of gastro-intestinal responsiveness to fatigue, associated as they often are with low blood pressure, the only way is to let the man rest on the Saturday, take his exercise on the Sunday, and then he will be a king on Monday.

Let me give another example. A spare man of efficiency and conscience (this ilk so often suffers) works all day in the city, and in order to "keep fit" walks home, say, two or three miles at night. He complains of dyspepsia and frequent headaches of the migraine type. Why? The physical exercise following his mental labour was too much for him; the motility of his upper alimentary tract gave out, indigestion followed, and this provocation—perhaps a toxaemia—caused, in a man with an inherent tendency to headache, migraine attacks sometimes conforming to classical description and at other times atypical. Had he not possessed this innate liability to headache, he would have been a flatulent dyspeptic, and perhaps had his appendix or gall bladder out, or had colopexy performed. If he had not possessed a gastro-intestinal tract over-responsive to fatigue he would probably have had recurring attacks of hemicrania with visual phenomena. What cured him? Driving instead of walking, resting for half an hour in the recumbent position, careful attention

* Delivered before the South Staffordshire Division of the British Medical Association.

to warmth of his extremities, and a dinner of light solid first-cooked food with a small amount of good wine. This patient took his exercise exclusively at the week-end and with benefit; he was one of those who could not stand physical and mental effort at the same time.

Such patients often do not tolerate cooked fats. This means that their *hepatic capacity is naturally poor*, or is rendered so for the nonce by fatigue. They can take uncooked butter and even cream, but not cooked fats, and the latter will sometimes produce acetonuria. This is one of the reasons why sodium bicarbonate in full doses is the best remedy for some cases of migraine. For cyclical vomiting alkali and glucose by the rectum are sometimes followed by striking success.

The order of the symptoms will vary. In some the gastro-intestinal upset precedes the headache and in others the reverse order prevails. A recent letter in the BRITISH MEDICAL JOURNAL, signed "Consulting Surgeon," describes the association of acetonuria with cyclical vomiting in one of his children and with migraine in himself. The former he cured by magnesium carbonate and glucose, and the latter he relieved by sodium bicarbonate.

I will pass to another clinical picture. Given a proclivity to headache, and a responsive abdomen, and let it happen that the feet and hands become cold and the abdomen uncomfortable—beware! Warmth must be restored and only the lightest of food eaten. If not, the next movement of the bowel will be ineffective and the motion broken up. The bowel, though it opens, does not empty; there is retention of contents, the defences of the colon seem to weaken, and migraine—of classical or irregular type—will follow. If such a patient be given an ordinary aperient pill, especially a strong one, there is a liability of making him worse, for thereby the bowel is irritated and the defences further weakened, and he feels a worm—a condition described by the victim as "poisoned."

What happens? Provoked by cold, fatigue, or worry (and the worry need not be real, for these patients are sometimes of the "worriting" sort), there is spasm of arteries and of colon. The function of the latter fails—emptying is incomplete, toxic products get through, then follows headache. If no such proclivity to headache existed the patient would get an attack of so-called "colitis."

Abdominal Migraine.

A patient, aged 30, had periodic attacks coming on suddenly, and often in the night, with upper abdominal pain and vomiting. They lasted two or three days. A thorough abdominal exploration showed stomach, duodenum, gall bladder, and appendix to be normal. The latter was removed. Both the father and mother of the patient had been victims of classical migraine. Many such cases have been reported, and in some of them a phase of typical migraine attacks has given place to that of abdominal attacks.

ETIOLOGY.

In the understanding of the headaches we are considering, a number of factors, variable as to their presence and influence, have to be considered. These factors vary in different individuals and even in the same *individual* at different periods of life.

1. A proclivity to headache. Thus migraine is hereditary in more than one-third of the cases, and can sometimes be traced in one form or another through several generations.

> Dr. Yeatman describes himself as "One of the fifth generation of sufferers, propagated through the female line, complicated by gout, and always precipitated by exposure to cold or irregularity of meals, preceded by a feeling of cerebral discomfort, closely followed by general headache, a boring throb at the back of one eye, subsequent sickness, and gradual recovery, accompanied by free secretion of watery urine."

2. Anxieties, fears, repressions, and other psychical conditions.
3. Fatigue and exhaustion.
4. Gastro-intestinal: proneness to fatigue, leading to failure of motility and perhaps secretion, as already set forth. The brain and solar plexus are in error, the proportion and order of their responsibility varying.
5. Hepatic insufficiency.

In some cases several of these factors may contribute, whereas in others one will dominate. Thus you may have the subject troubled neither by fatigue nor anxieties, but the liver can only deal with the lightest food and will not tolerate alcohol; such persons will have periodic attacks of migraine, have a tendency to high blood pressure, and in middle life substitute gout for their headaches, though in these days the acute gouty arthritis is less common. On the other hand, migraine may result from half an hour's *acute anxiety* without any apparent association with digestive or metabolic changes.

DIAGNOSIS.

When we get beyond the precise boundaries and coherency of organic disease into disorders of function the aim of diagnosis is not to seek a label but to search out the why and the wherefore in each patient. The illness will be the result of reaction between external conditions and that particular patient's physiological and psychological make-up. The physician needs first to investigate the present disorder of function by all the tests at his command; next he must know the patient's physiological and psychological habit and workings; and lastly the circumstances of his mode of life and career.

I have given examples of states of body, and will now pass to the brief consideration of states of mind.

The victims of these headaches are often well educated and capable people in whom achievement counts for much, with the pride and hidden vanity that accompany its pursuit. At the same time they are sensitive to the dictates of conscience and duty, which easily become exaggerated and exacting. They thus keep their minds under the lash, and if fatigue supervenes they do not rest but lash themselves more. They strive for superiority; they try to avoid inferiority, and, if they fail, seek to disguise the fact from themselves by psychological pretext. If one adds that they are people of self-control and sometimes of reserve, it is easy to see that repressions and conflicts sometimes hidden under a plausible explanation lead to various failures of adjustment to daily life. Such "conflicts" come out in the pursuit of career, in sex relationships, in social ambitions. Headache is often an expression of the conflicts—with or without *concurrent* abdominal disturbance.

What the doctor has to do is to read and unravel the lines of force within the patient's mind when the latter is up against a concrete difficulty or trial. The treatment should be *ad hoc*. The doctor can then help the patient to understand himself, and point the way to the truth rather than crudely disclose it. So does diagnosis become the best treatment.

TREATMENT.

Treatment is in large measure a study of causes which are variable for different people but fairly constant for one individual.

In those people in whom the headache stands alone, and is the result of responsibility and stress, the day of rest is needed, but still more the right way of using it. So often the day of rest sees the same strenuousness and feverish activity as the day of work. It is relaxation which is needed, and its art requires study. Exercise to be beneficial must bear relation to the frame, physiological habit, and the week's work. There are times when the subject prone to headache needs a day or half a day in bed with windows open, the lightest of diet, and a diverting book. It is to be remembered that some headache victims have no twilight, no forewarning of fatigue, and in extreme cases their lives alternate between orgies of activity and prostration.

The best treatment is to show them the nature of the problem. In some cases an unusual somnolence, with or without yawning, in others an exaltation of fitness, may be danger signals, but often there is no warning. Some people must have fresh air. In the war many migraine subjects during their time in the trenches were immune from attacks. Eye-strain is an accepted exciting cause which needs no comment. Tobacco may be a cause, also alcohol, and—which is interesting—some victims are vulnerable to certain kinds of alcohol and not to others.

As regards the alimentary tract, I have already mentioned the importance of first-cooked foods, the avoidance of cooked fats, and in some cases restriction of sugar. Investigation in each case is needed.

People in whom the gastro-intestinal tract manifests their

fatigue should be careful to be warm when eating and to partake of light food when tired. Many an attack could be avoided by such precautions.

A word on aperients. Patients who are strong, of the gouty type, and whose headaches are mainly due to hepatic insufficiency, are benefited by routine administration of calomel and saline every ten days, but for many, if not most, headache subjects strong aperients are harmful. The dose of salts which would cover a sixpenny piece or a shilling, in the early morning, is sound because it stimulates the ampulla of Vater, but no fuller dose. Castor oil in doses of 1 to 3 drachms once or even twice a week helps many, and others can take the lighter aperients like cascara or senna.

I will not stay to discuss palliative measures; each subject must find his own best—an important thing, because the rule for the headache subject is to "carry on" if possible. Any palliative must be taken at the onset. Salicylate and bromide and sal volatile suits many. Phenacetin is invaluable; pyramidon for the few; cachet Faivre has staunch supporters, but is too depressing for some.

For those prone to acidosis sodium bicarbonate is the indication. Luminal is in some cases helpful, but its effects need watchfulness, because there are some patients it does not suit; thus now and then a blueness of lips may be noted, or again, a dullness or slight perversion of mental outlook.

Skilled massage of the head and neck, and manipulation which includes gentle traction of the head from the trunk, bring great relief to some people. But enough. Headache illustrates a problem which will increasingly occupy the attention of the medical profession—namely, the keeping of man in the path of "physiological righteousness."

Note.—A list of references given by Lord Dawson will be found at the back of the JOURNAL (p. 652).

THE SURGICAL TREATMENT OF PARALYSIS OF THE VOCAL CORD AND OF PARALYSIS OF THE DIAPHRAGM.

BY

LIONEL COLLEDGE, M.B., B.CH., F.R.C.S.,
SURGEON, EAR AND THROAT DEPARTMENT, ST. GEORGE'S HOSPITAL;

AND

SIR CHARLES BALLANCE, K.C.M.G., M.S., F.R.C.S.,
CONSULTING SURGEON, ST. THOMAS'S HOSPITAL.

II.—ELECTRICAL STIMULATION OF THE RECURRENT LARYNGEAL NERVE.

WHEN the recurrent laryngeal nerve is divided previous to the anastomosis of its distal end to the phrenic or some other nerve it has been the rule to stimulate it while the vocal cords have been observed through the laryngoscope. Abduction and adduction of the vocal cord on the side on which the recurrent laryngeal nerve is being stimulated are plainly visible. If, however, the undivided recurrent laryngeal nerve is stimulated both vocal cords move equally. The movement of the opposite vocal cord is obviously induced by a sensory reflex reaching the respiratory centre from the site of stimulation. Possibly also both vocal cords are moving in obedience to the sensory reflex. The movements of the two cords appear to the eye to be synchronous, the vocal cord of the opposite side not moving later in time than the one on the same side as the stimulation. In another experiment, in which on the side opposite to the stimulation an end-to-side recurrent laryngeal-phrenic anastomosis had been done nine months previously and the vocal cord on the side of the recurrent laryngeal-phrenic anastomosis had been for three months moving rhythmically with the opposite or normal cord, the stimulation of the undivided recurrent laryngeal nerve was followed by movements of both vocal cords, but the movement of the opposite vocal cord was much more pronounced than the movement of the vocal cord on the site of stimulation.

This result brings this experiment into line with other experiments already described, and indicates that the nerve current passing through the phrenic nerve is stronger than that which passes along the recurrent laryngeal nerve in normal circumstances. Stimulation of the appropriate area of the cerebral cortex always induces a movement of both vocal cords and never of the opposite cord alone. The above experiment shows that the same obtains from stimulation of the undivided recurrent laryngeal nerve; the reflex causing movement of both vocal cords in this case probably comes from the medullary respiratory centre and not from the cerebral cortex.

There is, however, a possible source of error in interpreting all these results of stimulation of the recurrent laryngeal nerve. It is not possible for the arytenoideus muscle to contract without causing adduction of both cords, while contraction of the crico-arytenoideus lateralis muscle of one side will cause adduction of the corresponding cord. The general result of the stimulation of the recurrent laryngeal nerve is that when a very weak current is applied to the peripheral end of the divided recurrent laryngeal nerve adduction of the cord on that side only occurs, and it may be supposed that this movement is induced by contraction of the crico-arytenoideus lateralis, but if a little stronger current is used both cords adduct, so that the arytenoideus may be supposed to be contracting. These observations have been made on the monkey, the cat, and the dog. Sometimes the cord movements have been seen from above and sometimes from below.

Following the adduction of both cords abduction occurs, but why the cord on the opposite side should abduct it is difficult to understand, except that the cords in normal circumstances always move rhythmically together. No doubt the crico-arytenoideus posticus on the side of stimulation receives a stimulus to contract, but why is it that the corresponding muscle of the opposite side also contracts? The abduction excursions appear to be as active as the adduction movements.

The division of the superior laryngeal nerve does not make any difference, though it was thought before the experiment was done that the intimate anastomosis of the superior and recurrent laryngeal nerves in the larynx might enable a reflex stimulus via the superior laryngeal nerve to reach the respiratory centre. Stimulation by a weak current of the proximal end of the divided recurrent laryngeal nerve produced no movement of the vocal cords.

It is noteworthy that in a paper by H. K. Anderson[4] on "Paradoxical pupil dilatation" in lesions of the sympathetic on both sides of the neck, the conditions that evoke the paradoxical effect are stated to be excitement, dyspnoea, anaesthesia, and death. These conditions are also associated with paradoxical movements of the vocal cords.

III.—THE PARADOXICAL MOVEMENTS OF THE VOCAL CORDS.

Haldane writes:[5] "The respiratory centre is a small area situated in the medulla. When this area is destroyed all rhythmical respiratory movements cease. No definite anatomical group of nerve cells has been defined at the position occupied by the respiratory centre. It seems clear that it is at about the position which is sensitive to chemical respiratory stimuli. The central paths for the innervation of inspiratory and expiratory movements must be different, but in what sense the centre itself is double is still obscure."

Negus states[6] that he and McDowell have proved in cats that the contraction of the laryngeal and diaphragmatic muscles is not synchronous. The glottis opens before inspiratory movement of the diaphragm commences and closes before expiration begins. It is clear that at the end of expiration a stimulus causes inspiration to begin, while at the end of inspiration a signal causes expiration to begin. The contraction of the diaphragmatic, intercostal, and abdominal muscles in expiration is associated with the closure of the laryngeal channel, while the relaxation of the above muscles and the contraction of other inspiratory muscles in inspiration are associated with the opening of the glottis. Evidently these events are very closely and intimately connected. They are, as John Hunter said of the lungs and heart in life, in sympathetic connexion; and any alteration in rhythm or timing must interfere with the perfection of these organic life movements. Negus adds: "The obstruction offered by the glottis to passage of air causes prolongation of the time

taken to fill or empty the lung and thereby causes suitable delay in the timing of the signals for emptying or filling of the lungs—namely, the Hering-Breuer reflex." However this may be, and it appears to be true—and we are not now discussing the CO_2 content of the air in the lungs or blood or other chemical problems—either the diaphragm or the muscles of the vocal cords must be the factor in maintaining the respiratory rhythm. We are inclined to think that the diaphragm, the principal muscle of inspiration, must be the factor. We do not forget that the first respiratory act after birth is inspiration. The metronome in music sets the time: the question is, does the movement of the diaphragm or that of the vocal cords act as the metronome of the respiratory movements?

In our experiments the diaphragmatic contractions, as observed by Professor Elliot Smith, some months after certain anastomoses had been performed were quite normal; but in some instances, in which a double anastomosis had been carried out months previously on both sides of the neck, the vocal cords exhibited a paradoxical movement—with inspiration adduction and with expiration abduction. Before the second anastomoses were done on the left side of the neck the vocal cord on the right side of the neck was moving well with the opposite cord; but when the vocal cord on the left side began to recover from the paralysis it not only started to work in wrong time with the diaphragmatic contractions, but it prevailed on the vocal cord on the right side, which had for months been moving in a normal manner, to join it in a paradoxical movement.

Again, in another experiment (monkey) an end-to-side recurrent laryngeal-phrenic anastomosis was done on the right side and an end-to-end recurrent laryngeal-phrenic anastomosis on the left side. Six months after the first operation the right half of the diaphragm was contracting normally, and so was the vocal cord. On the left side the distal end of the divided phrenic nerve was not anastomosed to any other nerve, and the left half of the diaphragm remained completely paralysed. Six months after the recurrent laryngeal had been anastomosed end-to-end to the phrenic nerve the left vocal cord was moving in a normal way with the other cord. Why in this monkey is there no paradoxical movement of the vocal cords? Indeed, in this monkey there never has been any trace of stridor or difficulty of breathing. The answer seems to be that though the left half of the diaphragm is completely paralysed, the right half is working naturally through nerve influences passing down the phrenic nerve, and the suggestion is made that this half of the diaphragm is acting as a metronome of the respiratory signals.

When both halves of the diaphragm are contracting in consequence of stimuli passing through the descendens noni-phrenic anastomoses and both vocal cords are moving in obedience to signals traversing the recurrent laryngeal-phrenic anastomoses, some factor, it appears, may arise—for example, deep anaesthesia—which disturbs the normal timing of the contractions of the laryngeal and diaphragmatic muscles. No one of these groups of muscular fibres is working under normal conditions, though under such conditions their life and movement are in intimate and sympathetic connexion. There may be delay in the receipt of one or more of the appropriate signals; the longer distance which the nerve current has to traverse and the possible obstructions *en route* may have some adverse influence; or it may be, and it is probably true, that the laryngeal and diaphragmatic muscles get out of step because no one of these four groups of muscles is able, in the new and strange circumstances of their active life, to act as the metronome of the complicated respiratory movements.

IV.—THE DIAPHRAGM.

When the experiment was performed of dividing the phrenic nerve and uniting the end of the proximal segment to the divided end of the distal segment of the recurrent laryngeal nerve, the question arose how best to anastomose the distal end of the phrenic nerve to some other nerve, so as, if possible, to provide for the recovery from paralysis of the corresponding half of the diaphragm. The problem was solved by dividing the descendens noni and uniting the proximal end to the distal end of the phrenic nerve.

In the monkey experiments, when the main trunk of the phrenic nerve is mentioned, the main trunk formed by the union of the roots coming from the third and fourth cervical nerves is meant, as the root derived from the fifth cervical nerve has never been demonstrated during an experiment. In the dog, when the main trunk of the phrenic nerve is referred to, the main trunk formed by the union of the roots coming from the fifth and sixth cervical nerves is meant; the root, a considerable one, which arises from the seventh cervical nerve or brachial plexus, is placed at the upper opening of the thorax, and has never been seen during an experiment.

In the monkey, presumably as in man, the root of the phrenic from the fifth cervical nerve is variable, and when present small. In the dog, however, the root of the phrenic from the seventh cervical nerve is of fair size, and can easily be demonstrated by dissection. It is of much interest to note that in the monkey division of the phrenic trunk formed by union of the roots derived from the third and fourth cervical nerves, and in the dog division of the trunk of the phrenic nerve formed by union of the roots derived from the fifth and sixth cervical nerves, is followed in each instance by complete paralysis of the corresponding half of the diaphragm. The root of the phrenic from the fifth cervical nerve in the monkey when present probably innervates a special area of the diaphragmatic muscle. The same is probably true in the dog concerning the root of the phrenic nerve from the seventh cervical nerve. If this is correct then these special areas of the diaphragm ought to be the first to recover function—that is, if they ever really lost their power to function.

It may be suggested that if one cervical root of the phrenic nerve is divided the recovery of the contractile function of the whole of the corresponding half of the diaphragm is due to the spread of the healthy terminal filaments of the phrenic nerve to the paralysed area of the muscle. This is contrary to what is known of the recovery or continued palsy of muscular tissue in all other parts of the body. As in end-to-end anastomosis of the phrenic nerve to the recurrent laryngeal nerve there follows after a time a recovery of function of the vocal cord muscles, so in descendens noni-phrenic anastomosis it is reasonable to believe that the recovery of the diaphragmatic muscle is a direct consequence of the anastomosis. Besides, by experiment we know that in a monkey fifteen months after the division of the trunk of the phrenic nerve formed by the union of the roots from the third and fourth cervical nerves the corresponding half of the diaphragm remains completely paralysed. Further, the microscope demonstrates that the phrenic nerve distal to its anastomosis with the descendens noni nerve recovers its normal anatomical structure, just as the recurrent laryngeal nerve distal to its anastomosis with the phrenic nerve resumes its normal microscopical appearance. Electrical stimulation also of these anastomoses gives rise to the normal corresponding muscular contractions.

Keith[8] describes the origin and development of the diaphragm.

> "The branchial muscles which formerly forced water through the gill slits are now transmuted into pharyngeal muscles and help to pump air into the lungs, thus acting as muscles of inspiration. The muscles of the body wall are modified to form muscles of expiration. It is worthy of notice that each half of the mammalian diaphragm is developed from two embryonic muscular sources:
>
> "(*a*) *A sterno-costal portion* derived from the ventral longitudinal musculature of the embryonic neck. These muscular sheets give rise also to the rectus abdominis and the depressor muscles of the hyoid bone and larynx.
>
> "(*b*) *A special or vertebral portion* arising from the bodies of the vertebrae and arcuate ligaments, and derived from the cervical part of the transversalis.
>
> "The nerve supply of the diaphragm also points to the fact that there are two distinct muscular elements in the diaphragm. The phrenic nerve when it reaches its corresponding half of the diaphragm divides into two branches—a vertical to the right and left ventro-lateral parts (from the third and fourth cervical nerves) and a dorsal branch (from the fourth and fifth cervical nerves) to the right and left dorsal parts."

Notwithstanding the complicated story of the evolutionary history of the muscle of the diaphragm there is no evidence that any portion of the muscle has a double nerve

supply. It is of interest to note that the depressor muscles of the hyoid bone and larynx and the rectus abdominis are so closely associated in development with the sterno-costal portion of the diaphragm, all these muscles being associated with the respiratory movements.

As in the monkey the roots of the phrenic arise from the third, fourth, and fifth cervical nerves, and in the dog from the fifth, sixth, and seventh cervical nerves, the site of section of the descendens noni nerve for the purpose of doing a descendens noni-phrenic anastomosis may be different. In the monkey the descendens noni nerve is divided above the origins of the branches to the depressor muscles of the hyoid bone and larynx, and the proximal end is united to the distal cut end of the phrenic nerve. It is then desirable to do another anastomosis—namely, to unite the distal cut end of the descendens noni nerve to the lower border of the hypoglossal nerve (end-to-side anastomosis)—so as to obviate permanent paralysis of the omo-hyoid, sterno-hyoid, and sterno-thyroid muscles. (Fig. 22.) This anastomosis has been performed in man, and in animals many times, and always with success. The distal cut end of the descendens noni nerve has in some instances been united, not to the hypoglossal nerve, but to the phrenic nerve, end-to-side, above the recurrent laryngeal-phrenic end-to-end anastomosis. In the dog the descendens noni nerve can be divided below the origins of the nerves to the omo-hyoid, sterno-hyoid, and sterno-thyroid muscles; the proximal cut end can then be united, end-to-end, to the distal cut end of the phrenic nerve. In these circumstances it does not appear necessary to provide for the anastomosis of the distal end of the descendens noni nerve with any other nerve. Whether it would be best in all circumstances to sever the descendens noni above the origins of the nerves to the depressor muscles of the larynx and hyoid bone, when the object in view is the recovery of diaphragmatic paralysis, is not clear.

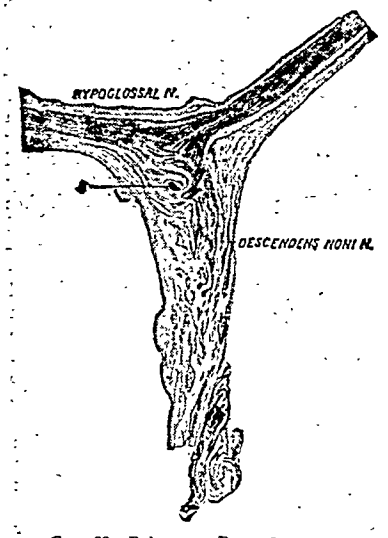

FIG. 22.—Baboon. Descendens noni-hypoglossal anastomosis, end-to-side. Specimen obtained fourteen months after the operation. Strocbe stain; *s*, remains of suture. Complete recovery of function of sterno-hyoid, sterno-thyroid, and omo-hyoid muscles.

In the dog recovery of the functions of the diaphragm is obtained by dividing the descendens noni nerve below its branches. The descendens noni nerve must certainly have many more nerve fibres, and nerve fibres too definitely associated with muscular action, above the origins of the nerves to the depressor muscles than below them. In the monkey the nerve below these branches is very small, but in the dog it is of fair size, and continues its course through the upper opening of the thorax. In man if it was necessary to divide the phrenic nerve there can be little doubt that it would be the right practice to divide the descendens noni nerve proximal to the place where its first branch is given off.

The descendens noni nerve, like the facial artery, has a tortuous course, as it lies among structures which are always in movement and constantly altering their length and position; hence when the nerve is dissected out it is of sufficient length so that it can be made to extend to any desired place.

In some instances one of the roots of the phrenic nerve was divided (instead of dividing the main trunk of the phrenic nerve), the proximal cut end of the root being united end-to-end with the distal cut end of the recurrent laryngeal nerve, while the distal cut end of the root of the phrenic nerve was anastomosed end-to-end with the proximal cut end of the descendens noni nerve. If the descendens noni nerve had been divided above the origins of the nerves to the depressor muscles then, as described above, a further anastomosis of the distal end of the descendens noni would be carried out.

In one instance an end-to-side anastomosis was performed, the end of the recurrent laryngeal nerve being united to a root of the phrenic nerve; the result being a partial paralysis for some months of that portion of the diaphragm supplied by the nerve fibres of the injured root.

It does not appear that there is any advantage in choosing a root, instead of the main trunk, of the phrenic for anastomosis with the recurrent laryngeal nerve; indeed, in one experiment the final recovery of the function of the diaphragm appeared to be delayed by the employment of this plan of anastomosis.

EXPERIMENT XII.—*Baboon.*

In this instance when the main trunk of the phrenic nerve on the *left* side had been divided and its proximal end sutured, end-to-end, to the divided recurrent laryngeal nerve, it was noticed that a large nerve was arising from the fourth cervical nerve close to the origin of the root of the phrenic nerve from the fourth cervical nerve. This large nerve received also a smaller root of origin from the third cervical nerve and passed down the neck for some distance near the phrenic nerve. It was the descending superficial cervical nerve which afterwards divided into suprasternal, supraclavicular, and supra-acromial branches. The trunk of this nerve was divided and its proximal end was sutured end-to-end to the distal cut end of the phrenic. (Fig. 23.) This union of the phrenic nerve with a sensory nerve seemed to be justified by the surprising results obtained by union of the lingual, glosso-pharyngeal, and cervical sympathetic nerves with the facial nerve. It would seem that the actual pathway of a nervous impulse is not of such moment as has been hitherto generally believed, as long as the nerve cells from whence issue the nerve impulses (in this case the nerve cells of the respiratory centre) and the nerve fibre endings (in this case in the muscle elements of the diaphragm) are intact. Sir David Ferrier was present at this operation.

A week after the operation some anaesthesia in the region of the distribution of suprasternal, supraclavicular, and supra-acromial nerve branches was demonstrated. *Five months* after the operation no anaesthesia of the skin in the region of distribution of these nerves could be made out, but the monkey was difficult to examine and the examination was not very satisfactory. *Eight months* after the operation the left vocal cord was moving in tranquil respiration rhythmically with the vocal cord of the opposite side and to an equal extent.

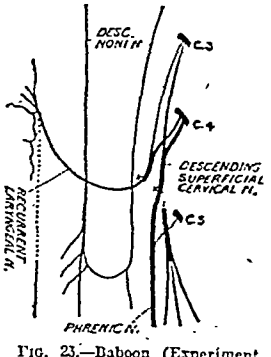

FIG. 23.—Baboon (Experiment XII). Recurrent laryngeal-phrenic end-to-end anastomosis. Descending superficial cervical-phrenic end-to-end anastomosis.

The Diaphragm.—Dr. Eidinow, with his radiographic screen at the Hampstead Research Institute, reported that the left half of the diaphragm was contracting well; in fact, there was no difference in the contraction movements of the two sides of the diaphragm.

This experiment remains a single one and therefore must not be too much relied upon. Unfortunately a week after Dr. Eidinow's examination the baboon became ill and had to be destroyed.

In other instances the cut end of the recurrent laryngeal nerve was united, end-to-side, to the main trunk of the

phrenic nerve, either to a small lateral incision made in the side of the phrenic nerve, or to a small median incision made in the middle of the phrenic nerve. In these cases no further anastomosis was necessary. An immediate partial paralysis of the corresponding half of the diaphragm results, and in all probability after a few days the cellular invasion at the site of anastomosis causes an anatomical division of the trunk of the phrenic nerve, so that complete paralysis of the corresponding half of the diaphragm ensues. But this paralysis is evanescent and passes off in three or four months.

This method of anastomosis — recurrent laryngeal-phrenic anastomosis, end-to-side—appears to be the method of choice for operations on man, as has been said in the previous remarks on the vocal cords. It simplifies the operation; it avoids the making of more than one anastomosis; it is satisfactory in that it promises recovery of the movement of the vocal cord, and in that it promotes recovery of the function of the diaphragm by regeneration of the phrenic nerve itself.

On one occasion, when the descendens noni and hypoglossal nerves were exposed, the hypoglossal nerve was stimulated. The thyro-hyoid muscle contracted and the depressor muscles relaxed; thus a typical Sherringtonian phenomenon was observed of contraction and relaxation of opposing muscles. The reverse experiment, of stimulation of the descendens noni nerve, which caused contraction of the omo-hyoid, sterno-thyroid, and sterno-hyoid muscles, should have been associated with relaxation of the thyro-hyoid muscle, but this could not be determined with certainty because of the overlying structures.

It is not possible to determine with accuracy whether half the diaphragm is in part or completely paralysed by observing or palpating the movements of the abdominal wall and costal arches. Dr. Eidinow kindly made some examinations at the Hampstead Institute for Research by means of the radiographic screen, and the results were also observed by Sir David Ferrier, the late Sir Frederick Mott, and Professor Leonard Hill. It was believed in each instance that the previously paralysed diaphragm was contracting again.

It was then decided to take some of the animals to the radiographic department of the Anatomical Institute of University College, Professor Elliot Smith having kindly promised to examine and report on the condition of the diaphragms in these animals. Dr. Beattie and Mr. Melville also observed the contractions of the diaphragmatic muscle through the radiographic screen. It will be seen from the reports of experiments that recovery of the muscular contraction of the diaphragm had taken place in each case.

V.—The Method Employed for Filming the Cords. (See Figs. 24 and 25.)

We are much indebted to the British Instructional Film Company for the painstaking effort which they made to film the vocal cords. The following are the chief points of the method employed:

1. A special high and solid table was made so that when the animal was anaesthetized and placed on it the eye of the observer, when standing, was on a level with the vocal cords.

2. A powerful beam of light from an arc lamp, A, was directed on and reflected from a small mirror through a special laryngoscopic tube, X. In length this tube was 5 inches along the upper border and 4 inches along the lower. The beam of light, before it reached the mirror, was caused to pass through a film of water, B. In this way the heat rays were cut off.

3. The inner extremity of the laryngoscope was a little larger than would ordinarily be employed for examination considering the size of the animal. It measured three-quarters of an inch from side to side and a millimetre more than half an inch in the vertical direction. The whole tube was oval in shape, and gradually increased in size till at the outer extremity it measured 2 inches from side to side and $1\frac{5}{8}$ inches in the vertical direction. The oval shape facilitated the passage of the beam of light, F, down the tube to the region of the vocal cords. The tube itself was blackened inside so as to prevent any reflection of light except from the vocal cords. A black oval screen, Z, was fitted around the outer extremity of the laryngoscope. It projected $1\frac{1}{2}$ inches on either side of the outer extremity of the laryngoscope, and in the vertical direction the screen extended $1\frac{1}{3}$ inches above the opening of the tube and three-eighths of an inch below.

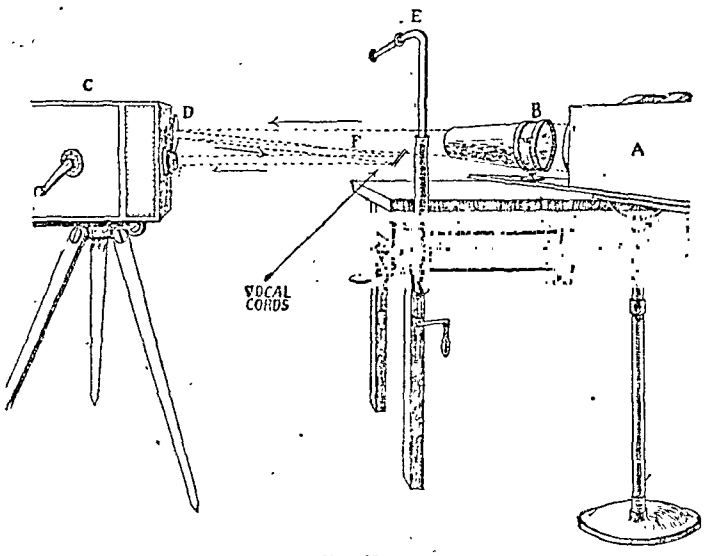

FIG. 24.

4. The laryngoscope was fixed to the ordinary suspension apparatus of Killian, E, by a metal rod. Thus unnecessary movement was avoided. In this rod was a hinge, Y, which could be fixed. The hinge allowed of the inner extremity of the laryngoscope being tilted a little upwards and downwards so as to facilitate the best exposure of the vocal cords.

5. The reflector, D, was attached close to the lens of the cinematograph camera, so that the light was reflected down the laryngoscope as nearly parallel as possible to the optical axis of the camera, C.

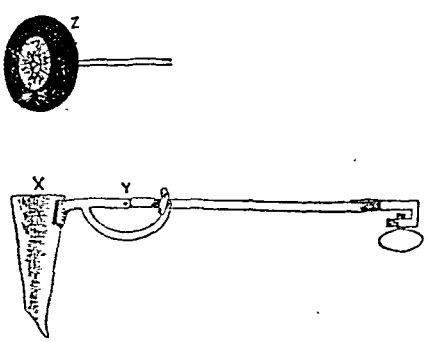

FIG. 25.

6. The anaesthetized animal was fixed approximately in position with a number of small sandbags. Then fine adjustments were made by means of the vertical and horizontal movements of the suspension apparatus and the hinge already referred to situated close to the laryngoscope.

7. One of us (L. C.) found it easy to manipulate the apparatus.

CHOLECYSTOGRAPHY.

BY

D. P. D. WILKIE, M.Ch., F.R.C.S.,
PROFESSOR OF SURGERY, UNIVERSITY OF EDINBURGH;
AND
C. F. W. ILLINGWORTH, M.B., F.R.C.S.E.,
CLINICAL TUTOR AND SENIOR CLINICAL ASSISTANT, ROYAL INFIRMARY, EDINBURGH.

IN the two years which have elapsed since Graham introduced the method of cholecystography a very large amount of evidence has accumulated as to its value and the discomfort or dangers which may attend its use as a routine method of clinical diagnosis. When any new method is on trial, particularly when it is one requiring the intravenous administration of a new chemical compound the manufacture of which is not fully standardized, there are apt to be a few instances of alarming disturbances which further experience proves to be readily avoidable.

In our earlier cases we used a dose which was larger than that recommended by Dr. Graham, but which in our hands gave rise to no alarming symptoms. The record of a fatal case, where this larger dose was used, has led to a certain apprehensiveness in regard to the use of the method which we greatly regret, and it is due to Dr. Graham to say that no case of serious complication has followed an injection of the drug as practised and recommended by him. Our own experience has been that the larger dose (5.5 grams) which we used in our first 50 cases, having based our practice on that of the Parisian hospital where we first saw the method employed, is unnecessary, and that sufficiently good shadows can be obtained with a smaller dose (3 to 4 grams). It cannot be too strongly emphasized that the solution (40 c.cm.) must be freshly prepared, and must be injected slowly and with care. In our last 60 cases there have been no severe reactions, and in the vast majority no noteworthy disturbance of any kind. Whilst in some clinics the oral method is that in general use and gives satisfaction, we have seen no reason to abandon the intravenous use of the drug, and believe it to be the more certain and accurate method.

As to the value of the test as an aid to diagnosis there can no longer be any doubt. The total absence of a shadow, in a case with the clinical symptoms of gall stones, is reassuring and convincing evidence of the necessity for operation. The presence of a perfectly normal gall-bladder shadow, in a doubtful case of dyspepsia, is strong, if by no means absolute, evidence that the gall bladder is not at fault. Perhaps the most beautiful piece of evidence is where, in the doubtful case, the gall bladder is outlined and in it is visible a negative shadow where a cholesterin stone has displaced the dye. The faint and poor shadow indicating defective concentration is almost pathognomonic of a cholecystitis with or without stones. Hardly less useful in diagnosis is the displaced or deformed gall-bladder shadow, in the case of a swelling in the right hypochondrium, indicating a growth or other swelling in an adjoining viscus. With increasing experience we find ever more numerous the helpful points of evidence furnished by this radiographic test.

Before analysing the clinical material at our disposal we give an exact description of the method now employed by us. In the evening, twenty-four hours before the injection is given, the patient takes a dose of liquorice powder. The following day a skiagram of the upper abdomen is taken. At 9 p.m. 3.5 grams of tetra-iodo-phenol-phthalein (British Drug Houses), freshly dissolved in 40 c.cm. of distilled water, is given slowly into the median basilic vein, great care being exercised that not a drop escapes into the subcutaneous tissues. At 9 o'clock the following morning a skiagram is taken. A small barium meal is then given, and as the barium is escaping into the duodenum another skiagram is taken to demonstrate the relation of the shadows of gall bladder and duodenum. At 1 p.m. a meal rich in fat is given, and at 3 p.m. a final radiogram is taken to show the emptying power of the gall bladder.

We have now examined 158 cases, and in 132 of these the data obtained have been controlled by subsequent operation.

Normal Gall-bladder Shadow.—In 58 cases the gall bladder presented what was judged to be a normal shadow. In 50 of these a normal gall bladder was disclosed at operations carried out for a variety of upper abdominal lesions. In one case several very minute calculi were present in a gall bladder of normal colour and texture. In one case a single cholesterin stone, the size of a pea, was removed from what appeared to be a healthy gall bladder. In 3 cases there was definite evidence of a mild chronic cholecystitis, confirmed by microscopic examination, and in one of these, where the gall bladder was removed, a small lipoid papilloma was present. In the remaining 3 cases there was a mild but undoubted catarrhal cholecystitis, and streptococci were grown on cultures made from a portion of the wall. It is thus seen that an apparently normal cholecystogram is not quite conclusive evidence that the early stages of disease in the gall bladder are not present.

Absent Gall-bladder Shadow.—In 50 cases no shadow could be detected in the radiogram. In 44 of these the gall bladder was grossly diseased. In many the cystic duct or neck was occluded by a calculus, in others the viscus was completely filled with stones, in yet others it was shrivelled and functionless. In 13 of these 44 cases there was obstruction of the common duct and the patient was jaundiced. In 6, although no dye entered the gall bladder, calculi were clearly visible in the film. In 6 cases, in spite of the absent shadow, a normal gall bladder was disclosed at operation. These cases were very difficult to explain, as in all the ordinary technique had been followed. Possibly a temporary kinking of the cystic duct was responsible for the failure of the dye to enter the bladder. Certainly in two of them normal cholecystograms were obtained some weeks later. Most of them occurred in our earlier cases, and we are inclined to attribute the fault more to some mismanagement than to any inherent weakness in the test.

Faint Gall-bladder Shadow.—In 10 cases the gall bladder was faintly visible, but there was obviously defective concentration of the dye. In 3 of these there were negative areas due to stones. In all of them a very definite chronic cholecystitis was found at operation and the gall bladder was removed. It is obvious that only after considerable experience with a particular technique and with a well established standard for comparison can conclusions be drawn from mere variations in the density of such shadows.

Shadow of Gall Bladder and Calculi.—In this group are included 11 cases; in 5 the gall bladder was clearly outlined and in addition there were positive shadows of calculi. In 6 cases negative areas in the shadow of the dye indicated the presence of cholesterin stones. Operation was carried out in all these cases, and the *x*-ray evidence was correct in each instance.

Displaced or Distorted Gall-bladder Shadow.—In this group there were 5 cases. In all the presence of a swelling below the right costal margin made the diagnosis of a distended gall bladder a possibility. In two cases the shadow of the gall bladder was visible below the swelling, which in one instance was a sarcoma, and in the other a hydatid of the liver. In two cases the gall-bladder shadow was present as a concave shadow lying over and above the swelling. In both instances this proved to be a growth of the hepatic flexure of the colon. In the fifth case the shadow lay in front of the swelling, which was later shown by pyelography to be a hydronephrosis.

Toxic Symptoms following Injection.

It may be stated at once that in no instance in our series of 158 cases have toxic symptoms, giving cause for alarm, been noted. In one case symptoms of collapse supervened during the injection, which was stopped before quite one-half of the usual dose had been given. The patient rapidly recovered with no untoward after-effects.

In 93 cases there were no toxic symptoms.
In 27 cases there was some nausea.
In 33 cases there were nausea and vomiting.
In 2 cases the patient complained of tingling in the limbs.
In 1 case a rigor followed the injection.
In 1 case nausea with headache was complained of.

There can be no doubt that with the reduction of the dose which we have made in our last 60 cases the toxic

symptoms have been markedly reduced and the radiographic results no less valuable, if not quite so striking. An injection of 4 grams for a stout subject and 3 grams for one of slender build, in each case dissolved in 40 to 60 c.cm. of distilled water, may be reckoned a perfectly safe dose. We have been unable to recognize any particular benefit from special preparation, or from the regular dosage with alkalis, which was followed scrupulously in our earlier cases. We have as yet had no opportunity to test the newer drug, phenol-tetra-iodo-phthalein, which, in Graham's clinic, is found to be less toxic than the tetra-iodo-phenol-phthalein.

Conclusions.

Cholecystography is a method of real clinical value in the diagnosis of diseases of the gall bladder. Not only does it show whether the gall bladder is functioning, but also how well or how ill it is functioning. It will frequently disclose the presence of gall stones which do not show in the ordinary radiogram. It may, by showing the relation of the gall bladder to an abdominal tumour, give strong presumptive evidence as to the site of the growth and the possibilities of surgical treatment.

Using pure sodium tetra-iodo-phenol-phthalein in a dose not exceeding 4 grams, freshly dissolved, and injected intravenously very slowly, no disturbing toxic symptoms need be feared. *X*-ray films made twelve hours after injection and six hours later, after a meal containing fat, should give reliable evidence as to the functional capacity of the gall bladder.

The method has its limitations, and an apparently normal cholecystogram does not exclude the possible presence of a small cholesterin stone or mild degrees of infective cholecystitis.

CHOLECYSTOGRAPHY.

THE RESULTS OF 125 CONSECUTIVE CASES EXAMINED BY THE ORAL ADMINISTRATION OF THE SALT.

BY

J. H. MATHER, B.Sc., M.B., CH.B., D.M.R.E.LIVERPOOL,

ASSISTANT LECTURER IN RADIOLOGY, UNIVERSITY OF LIVERPOOL; HONORARY RADIOLOGIST, ROYAL SOUTHERN HOSPITAL, LIVERPOOL;

AND

W. ROBERT WILLIAMS, M.D., CH.B.LIVERPOOL, F.R.C.S.ENG. AND ED.,

SENIOR ASSISTANT SURGEON, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

THE existence of such divergent views as to the relative values of the intravenous and oral methods of cholecystography has led us to believe that our results will be of interest.

The difficulty of oral administration appears to be due to the fact that the compound is decomposed by the hydrochloric acid of the stomach, converting the soluble salt into the insoluble free acid, which acts as an irritant and may be vomited. Endeavours were made, therefore, to provide for its passage through the stomach and liberation in the small intestine, where it would be absorbed and carried by the portal system directly to the liver. Stewart[1] of New York reported recently that he had obtained successful cholecystograms by enclosing the dye in keratin-coated gelatin capsules and using *x* rays twelve hours later. Other observers, however, do not seem to have met with the same success, and presumably their difficulties have been due to the unreliability of the preparation used, and also to the unsuitable nature of the capsule and its coating. In many cases the drug appears to have been liberated in the stomach, and vomiting has ensued, or the coating has been so resistant to the digestive juices that the capsules have been passed on into the colon intact.

In our early cases the results were similar. A British preparation of sodium tetraiodo-phenolphthalein, made into capsules by the manufacturers, was used. The capsules were not dissolved, as many as eight and even fourteen being seen in the large bowel next morning. We next obtained capsules of the iodine salt prepared in the United States. The results obtained were good but the cost excessive. Finally, an American preparation of sodium tetraiodo-phenolphthalein made up into capsules by the dispenser of the hospital seemed to be the most suitable. Different coatings were tried, but the best results were obtained by the following method.

Preparation of the Capsules.

The drug used is the sodium tetraiodo-phenolphthalein obtained from Messrs. Kodak, Ltd.; 0.3 gram of the salt is placed in a gelatin capsule, which is then given three coats of a keratin solution, made (using Merck's keratin) according to the *British Pharmaceutical Codex* formula. The capsules are allowed to dry in the air after each coat without heating. They are now prepared by a Liverpool firm of wholesale druggists from the salt supplied by Messrs. Kodak.

It is important (1) that the salt be obtained as fresh as possible and carefully stored, and (2) that the capsules be made up freshly. If capsules are kept for more than seven days the coating is not dissolved readily in the small bowel.

Technique Employed.

Twenty-four hours before administering the drug the patient is given an aperient, preferably one ounce of castor oil. On the day preceding the examination the patient takes an ordinary diet containing fats. No food is allowed after 6 p.m. and no further aperient is given. Between 9 and 9.30 p.m. the capsules are swallowed whole with sips of water. (For an average patient fifteen capsules are taken—that is, 4.5 grams of the salt.)

At 9.30 the following morning the first radiogram is taken, using the Potter-Bucky diaphragm, the patient being in the prone position. The patient returns at 12.30 p.m., and the second radiogram is taken. If the gall bladder appears normal at both these examinations the patient is told to take a meal containing fat and to return between 3 and 4 p.m. for a third radiogram. Should the gall bladder be empty or nearly so the examination is concluded. If it has not emptied, the patient is asked to return the following day. But in those cases where there is no suggestion of a gall-bladder shadow on both the 9.30 a.m. and 12.30 p.m. radiograms the examination is carried no further and a "pathological gall bladder" is reported.

If the gall bladder is normal a definite shadow is visible on the radiogram taken twelve hours after administering the dye. At the end of fifteen hours the shadow is denser and usually smaller. The radiogram taken two or three hours after the meal containing fat shows either no gall-bladder shadow or one very much reduced in size. If the gall bladder is not markedly smaller the patient is examined the following day.

Using the method outlined above cholecystography is as satisfactory as with the intravenous method, and it has the advantage that the preliminaries are very much simpler. Though the shadow with the oral method appears a little later, it is equally dense and yields equally satisfactory evidence of the form and function of the gall bladder.

It is important to realize the theoretical considerations involved in the use of this test. It demands a liver capable of secreting the dye into the bile capillaries, a patent cystic duct to allow of its passage into the gall bladder, and, finally, a mucous membrane sufficiently healthy to concentrate it by the reabsorption of water. It follows, therefore, that the normal gall bladder yields the densest shadow. At the same time it is obvious that a variety of conditions—adhesions and tumours pressing on the cystic duct or gall bladder, infections of the mucous membrane interfering with its power of concentration, thick tenacious debris in its interior—in addition to stones either in the cystic duct or gall bladder itself, can cause all degrees of variation from the normal density to complete absence of shadow. In actual practice, however, as seen from Table I, a definite and unequivocal complete absence of shadow occurs in 77 per cent. of the cases reported as pathological. Probably the only contraindications to cholecystography by this method are (1) advanced disease of the liver—for example, cirrhosis, secondary carcinoma—and (2) pyloric stenosis. Both these conditions, however, should be discovered by other methods, and there is little likelihood of their being present to confuse the issue in the type of case in which this investigation is being carried out.

Toxic Effects.

In our own series of cases we have seen no severe reactions. In two instances there was a slight rise of temperature, but in neither did it reach 100° F. Eight patients complained of nausea lasting a few hours, but only one of them actually vomited. This patient stated that she had vomited "purple material," but subsequent radiograms demonstrated a normal gall bladder which was unusually well defined on the *x*-ray film. Two somewhat

nervous patients vomited almost immediately after taking the capsules, which were returned whole, but this can hardly be attributed to any toxic effect of the drug. In one other case there was slight diarrhœa, the bowels acting three times during the night. All the other patients were apparently quite unaffected by the drug, and in no single instance did a patient fail to appear at the appointed time for the first *x*-ray examination.

Group 5:			
	Dense mass of adhesions at neck of gall bladder...		1
	Total cases operated on		35
	Total cases where *x*-ray diagnosis was confirmed ...		33
	Total cases where *x*-ray diagnosis was not confirmed		2
	Percentage of cases where *x*-ray findings were correct		94.3

Comments on the X-Ray and Surgical Findings.

The cases here reported were consecutive, arising in private and hospital practice, and have not been selected in any way. It will be observed that in a large number a normal gall bladder was outlined on the *x*-ray films. An interesting example in this group was seen in the case of a patient in whom a normal gall bladder containing three opaque stones was visualized; concentration occurred in the usual way and it also emptied after the fatty meal had been taken. From this it would appear possible for the gall bladder to function in a perfectly normal way despite the presence of stones. The patient's only symptom was occasional nagging pain under the right costal margin. The instance in this group where the *x*-ray diagnosis was not confirmed at operation was one of our earliest cases. Only a faint shadow was shown, but owing to our inexperience of the oral method it was interpreted as being normal. A similar finding now would undoubtedly be reported as pathological.

Of the cases falling into Group 2—that is, those where no shadow is seen—the *x*-ray and surgical findings point definitely to a non-functioning gall bladder. Although the *x*-ray finding is a negative one it is most valuable, and, if the preliminaries have been carefully carried out, can be definitely relied upon. Where the clinical signs have not been very suggestive of cholecystitis, it has been our practice to repeat the examination in those cases where no shadow was seen at the first examination. In two such instances a normal gall bladder was outlined at the second *x*-ray examination, the explanation in one case being that the patient had taken a breakfast of bread-and-milk before the 9.30 a.m. film was taken—the radiologist was not informed of this at the time. We were unable to account for the failure in the other case. Of the twenty-five cases falling into this group which were operated upon, the gall bladder was found to contain stones in 76 per cent.; in a further 8 per cent. there was marked cholecystitis, while in another 8 per cent. adhesions around the gall bladder were the most obvious pathological finding. In one of these latter cases, where the adhesions were merely divided and the gall bladder was allowed to remain, the dye test was repeated a fortnight later and a perfectly normal gall bladder was revealed. In one case only of this group the gall bladder was found to be normal at operation; it was not removed, and this patient's symptoms were not relieved.

It is well known that a considerable degree of cholecystitis and even stones can exist undiscovered until the gall bladder is opened and examined, either *in situ* or after removal, and in view of this we consider it the surgeon's duty to remove the gall bladder when the *x*-ray evidence points definitely to disease being present in the organ, even though its external appearance seems normal.

Of the three cases occurring in Group 3 there was one example of an hour-glass gall bladder, and one where the gall bladder filled slowly and had an irregular outline. The third filled and emptied normally, but was abnormal in shape and position. The patient was operated upon and found to have a pyloric ulcer with adhesions to the gall bladder, to account for the *x*-ray findings.

Of the eight cases in Group 4 where a shadow indicative of non-opaque stones was seen, four patients were operated upon and the *x*-ray diagnosis was confirmed. Usually the stones are very definitely outlined by the dye, and in Stewart's[2] opinion this is the most positive finding of all. But in a later paper[3] he expresses a warning against the diagnosis of stones by mottling alone, giving his reason that small circular bubbles of gas in the duodenum often overlap the gall bladder and closely resemble non-opaque stones.

It is in Groups 3 and 5, as Graham points out, that most errors of diagnosis occur. Among our cases which fell into the latter group the gall bladder was still outlined at periods varying from eighteen to thirty-four hours, although several fatty meals had been taken by the patients. In the case of the patient operated upon there was a dense mass of adhesions at the neck. It seems probable that a similar condition will be responsible for the delay in emptying in the case of the remaining instances of this group.

It is perhaps worthy of mention that only in six instances out of our series of 125 cases were opaque gall stones seen on the *x*-ray films.

Conclusions.

1. The success of the oral method depends on obtaining a reliable salt, careful coating and preparation of the capsules, which must be freshly used, together with first-class *x*-ray technique and intelligent co-operation on the part of the patient.

2. Cholecystography by the oral method is easier than the intravenous so far as the preliminaries are concerned, and yields equally satisfactory results from a radiographic point of view.

3. The proceeding is devoid of risk, and the toxic effects are practically negligible.

4. The surgical findings confirm the *x*-ray diagnosis in 94.3 per cent. of the cases.

We wish to thank Dr. R. E. Roberts for allowing us to include some of his private cases, and Mr. D. Douglas-Crawford and Mr. O. Herbert Williams for permission to use the findings in the cases operated on by them.

EPIDEMIC ENCEPHALITIS: THE PROPORTION OF PERMANENT RECOVERIES.*

BY

A. GARDNER ROBB, M.B., D.P.H.,

VISITING PHYSICIAN IN CHARGE OF THE BELFAST FEVER HOSPITALS.

I THINK it may be said that, after the passing of the earliest outbreaks of epidemic encephalitis of which this generation of physicians has had experience (six to ten years ago), the percentage of complete recovery was estimated by most writers on the subject at 20 to 30. Later writers express a more guarded opinion and generally record a much lower complete recovery rate. My own experience has been that in every outbreak the complete

* Abstract of a paper read before the Ulster Medical Society on January 27th, 1927.

recovery rate has been very considerably lower than 20 per cent. if the estimate be made, say, two or three years after the acute attack.

In the spring of 1924 an outbreak occurred in Belfast. In the three months April, May, and June 173 cases were admitted to the fever hospitals under my care. Though this outbreak was extensive and sudden it could not be said to have been of more than average severity as the death rate in the acute stage was 12.1 per cent.

These 173 cases form a compact group. Last autumn—that is, after two and a half years—with the assistance of Dr. W. B. Shane I made an attempt to ascertain the then condition of the 152 cases who had recovered from the acute attack. A paper of questions was sent out and replies received from the majority of the patients. Had these replies been taken as correct the figures would have been very different from those finally accepted. Our experience showed that statistics compiled upon such reports are altogether unreliable. Many patients who reported that they had remained quite well from the time of leaving hospital were found on examination to be very far from well; some who had so reported were found to be frankly Parkinsonian, some mentally deficient, etc.; 11 cases could not be traced. We were able to examine over 80 per cent., and received medical reports of the small remainder.

Epidemic Encephalitis: Results 2½ Years after Attack.
(Total cases 173.)

Died in acute stage	21	
Recovered from the acute attack... ...	152	
Of the 152 who recovered:		
Untraced	11	
Examined after 2½ years	141	
Of the 141 examined:		
Apparently well (after 2½ years)	13= 8.8	per cent.
Died of effects (within 6 months, 2; between 6 and 12 months, 3; between 1 and 2 years, 2)	7= 4.9	,,
Suffering from nervous symptoms of mild type	10= 7.0	,,
Showing "changed character"	18=12.7	,,
Showing mental symptoms (in mental hospital, 6; not in mental hospitals, 13)	19=13.4	,,
In other medical institutions	19=13.4	,,
Subject to convulsive attacks (epilepsy?)	2= 1.4	,,
Showing Parkinsonism (Stage I, 21; Stage II, 42; Stage III, 20)	83=58.8	,,
Partially incapacitated for work or school	29=20.5	,,
Totally incapacitated for work or school	84=59.5	,,

It will be seen that of those who survived the acute attack 8.8 per cent. were found to be well after two and a half years. I have no doubt were these cases again examined at the end of, say, five or six years from the onset this percentage would be further reduced.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PURULENT PERICHONDRITIS OF THE LARYNX.

CASES of purulent perichondritis of the larynx, when secondary to constitutional disease such as syphilis and tuberculosis, are not of common occurrence. When present as a complication the diagnosis may not be difficult. If secondary to malignant disease it is conceivable that the condition may not be easy to diagnose and the results to the patient may be disastrous. If confronted with a case of this nature when neither syphilis, tuberculosis, nor malignant disease can in any way be used as a guide, then a very careful process of exclusion, in the absence of previous experience, may have to be invoked; in any case the medical man should take the earliest opportunity of calling the laryngologist to his aid. The following case amply illustrates the urgency of these cases.

A woman, aged 61, had been attending her doctor for five weeks, first with hoarseness, and latterly with difficulty in breathing, which had become very much worse; she was sent to hospital with a view to admission.

I found there was marked stridor and slight pain on swallowing; the larynx was more or less fixed and appeared to be pushed forward, and pressure over the front of the larynx caused pain. There was a swelling on the right side of the thyroid cartilage which gave deep fluctuation. On laryngoscopic examination the left ventricular band was found to be red and swollen, obscuring the view. The right vocal cord could be seen to move slightly in abduction and adduction over a yellow swelling which extended across the middle line from right to left in its posterior half. No swelling could be seen in the pharyngeal portion of the cricoid or arytenoid region. The temperature was 101° and the pulse 140. No history of foreign body was elicited: tubercles were not present; the Wassermann test was not performed. A diagnosis of purulent perichondritis was made and immediate operation advised. Under general anaesthesia tracheotomy was performed and an incision made over the site of fluctuation; pus was evacuated and some escaped into the pharynx, but not into the larynx. There was no sequestrum, but roughened cartilage could be felt with the handle of the scalpel through the incision. There can be little doubt that there was a communication with the interior of the larynx; this suggests the importance of a preliminary tracheotomy in these cases.

The tube was removed on the third day. With the exception of a slight collapse four days after admission, from which she soon recovered, her convalescence was gradual and uneventful. She left hospital on October 23rd looking and feeling well, with voice and breathing normal, and the larynx functioning well.

Although I had no doubt as to the actual condition, the important guides, apart from the appearance of the swelling in the larynx, were (1) deep fluctuation felt on the right side of the thyroid cartilage, (2) the pulse, (3) the temperature. Rise of temperature may be absent when pus is established and locked up, but its presence in this case was an indication of urgency.

If there is a lesson to be learnt it is that the laryngologist should be called to see these cases before the stage of stridor is reached; at any moment a disastrous end may result.

TRANSPOSITION OF VISCERA.

THE following two cases of dextrocardia and transposition of organs, which were found in Arabs of the Sudan, seem worthy of record.

CASE I.

An Arab girl, aged 11, was brought to me suffering from malaria. While feeling for the spleen under the left costal margin I detected what I took to be the clear cut edge of the liver, and palpation of the right side revealed the spleen extending for the breadth of five fingers under the costal margin, with the typical notch opening to the left. The apex beat of the heart was visible in the fifth right interspace, one centimetre inside the right nipple line, and auscultation proved it to be a case of true dextrocardia. The girl was quite unaware of her condition, and the mother, father, and two sisters, who were examined, were found to have the heart in the normal position on the left side.

CASE II.

Within a week of seeing the first patient, a man, aged 25, came to me because of chest trouble. I found tuberculosis of the left apex, but could hear no heart sounds on the left side. Inspection revealed a faint apex beat in the fifth right interspace, half a centimetre inside the right nipple line. Percussion on the left side showed an area of dullness identical in size with the normal hepatic dullness, and in the corresponding position. The edge of the liver could just be palpated under the left costal margin. The spleen was not felt on the right side. The patient was fully aware of the abnormal position of the heart, but had kept the knowledge of it to himself fearing ridicule.

I can find no references in the literature to suggest that this condition is more common among the coloured or less civilized races, and the discovery of two such cases within so short a period and in the same locality may be pure coincidence.

I have to thank the Director of the Sudan Medical Service for permission to publish this note.

LABOUR RETARDED BY HYDROCEPHALUS TERMINATED BY DRAINING A SPINA BIFIDA.

I WAS called by a midwife to attend a woman in her third confinement. She had been in labour for six hours. The os was fully dilated. The presentation was a breech with extended legs. Under anaesthesia the legs were brought down and delivered with the body. A spina bifida was present with complete absence of the posterior arch of the spinal canal in the lower dorsal and upper lumbar region. No progress was made in labour, and a large hydrocephalus was diagnosed. Having a ready track to the ventricles it was deemed advisable to try to use it. The inner tube

of a Collins uterine douche tube was passed up the spinal canal into the ventricles and two quarts of fluid were drawn off. The uterine contractions immediately became strong and the flattened head was delivered. The puerperium was normal.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

STAFFORDSHIRE BRANCH.

Ovarian Endometriomata.

A MEETING of the Staffordshire Branch was held at Walsall on March 17th. In the absence of the President (Mr. W. C. Allardice), Dr. J. A. M. CLARKE took the chair.

Mr. S. W. MASLEN JONES read a paper on ovarian endometriomata and showed specimens which he had removed at operation. He discussed the causation of these tumours and summarized the rival theories held by Vernon Bailey, Sampson, and other workers. He explained the pathology of such tumours and emphasized the fact that the aberrant endometrium, which was the basis of the pathological condition, exercised its effect principally by a production of menstrual flux at a time which corresponded with the ordinary period of menstruation in the uterine mucosa. This production led to the formation of cystic cavities containing a chocolate-coloured fluid. A discussion followed regarding the significance of the occurrence of endometriomata in sites other than the ovary.

Lead Treatment of Cancer.

Dr. S. C. DYKE read a paper on the lead treatment of cancer. He recounted his experiences at Professor Blair Bell's clinic at Liverpool, and explained that the reasoned basis of the treatment was the special toxic effect of lead upon cancerous tissue. One of the greatest difficulties in the treatment was that the general deleterious effect upon the patient might outrun the specific local effect upon the tumour; the best results would be obtained consequently when a lead product was found which had a minimum general toxicity combined with a maximum local effect upon malignant cells. Dr. Dyke reviewed several cases which he had seen undergoing lead treatment, and he mentioned the particularly good results which had been produced in some cases in which partial removal of an inoperable tumour had been combined with treatment by lead. A discussion followed which related particularly to points in the technique of the treatment.

Medicine in the Past.

Dr. F. G. LAYTON read a paper on mediaeval medicine. He emphasized the benefits which would accrue to practising physicians if they had a greater knowledge of the history of medicine than was commonly the case, and he contended that many of the old procedures were much more logical than many methods of therapy which were practised at the present day. He indicated the lines upon which the ancients arrived at a diagnosis, and held that a knowledge of human nature was perhaps even more common among the old-time Egyptian physicians than it was among present-day medical men. He made a plea for treatment by dietetics and regimen, both of which he considered should have a more important place in therapy than was at present the case. A discussion followed contrasting modern with more old-fashioned methods.

The Eyes in Diagnosis.

Dr. G. F. HAYCRAFT read a paper on the pupils as an aid to general diagnosis, and gave a brief but very informative summary of the anatomy and physiology of the iris. He then recounted important points in the causation, diagnosis, and treatment of iritis. Turning from inflammatory conditions, the speaker showed how the iris might be affected in a large number of general diseases. The subsequent discussion centred round the effects of tuberculous disease on the iris, these effects being produced either by local interference with the nerve supply of the iris musculature or by the general asthenic condition seen in late stages of the disease.

Reports of Societies.

RETROPERITONEAL FIBROID.

AT a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland on March 11th, the President, Dr. D. G. MADILL, in the chair, Dr. D. CANNON read notes on a case of retroperitoneal fibroid, and showed a specimen.

A woman aged 36, with enlargement of the abdomen, had been married for four years, but had no children. She had been operated on for appendicitis. She looked worn, tired, and rather older than her years. Her periods were normal, except for slight dysmenorrhoea, and her heart, lungs, and kidneys appeared to be quite normal. Inspection and abdominal palpation revealed a *symmetrical semi-solid tumour, which filled the whole of the* abdomen. On bimanual examination the tumour appeared as a swelling of the posterior fornix, extending more to the left than to the right. By vaginal examination its stony hardness contrasted with the almost cystic feeling of the abdominal wall. The cervix uteri could be recognized high up underneath the symphysis to the right side. The diagnosis lay between an ovarian cyst complicated by a cervical fibroid, or a cervical fibroid or broad ligament fibroid which had enlarged to such an extent as to become an abdominal tumour. When the abdomen was opened the latter condition was found. During the process of enucleation severe bleeding was encountered, and so a rapid enucleation of the upper pole of the tumour was performed. Towels wrung out of hot saline were packed into the bed from which a portion of the tumour had been enucleated. The patient suffered from shock at this stage of the operation, but recovered after a short time. The lower pole of the tumour was enucleated with ease, and with scarcely any bleeding. The left ureter, which was displaced outwards, was followed to its disappearance into the parametrium, and was intact. The uterus, which had reached the level of the umbilicus, was pushed well over to the right side and the cervix was elongated. The peritoneum of the posterior wall of the left broad ligament and Douglas's pouch was spread over the intestines like a thick apron, and was adherent to them. All bleeding points were carefully secured. At this stage the peritoneum was separated quite easily from the intestines, and omental adhesions were tied and divided. The excess of peritoneum was removed, and the margin of the rent which was oozing blood was sewn all the way round with continuous catgut. The thickened peritoneum presented the appearance of the thickened tunica vaginalis seen in chronic hydrocele. The cavity from which the tumour had been enucleated was now considerably reduced. It was obliterated by mattress sutures, and rubber tubing which had been split and threaded with gauze was inserted into the obliterated portion of the cavity and taken out at the lower angle of the wound. The abdomen was closed, and the patient left the table in fair condition, but collapsed some hours later and died. There was no evidence of bleeding from the tubes.

Dr. Cannon thought that death was due to secondary shock as a result of haemorrhage; the patient had certainly not died from primary shock. He believed that she would not have died if he had performed a complete hysterectomy after the tumour was enucleated. In this way he could have tied off the main source of blood supply to the pelvis, and could have drained the retroperitoneal space through the vagina. The uterus could easily have been removed in the circumstances; it was only left because the patient was very anxious to have a child. During the time that Dr. Cannon had charge of the Gynaecological Department of St. Mary's Infirmary, Highgate, he had encountered four retroperitoneal tumours. They were all small; three were parovarian cysts, and one was fibroid. They had presented no difficulties. The present case belonged to a different category. Owing to the size of the tumour, the cavity from which it was enucleated was difficult to obliterate; it was undergoing degenerative changes, and had probably been infected; the cavity was therefore probably a vascular one.

The PRESIDENT said that this was one of the largest fibroids he had ever seen which had been enucleated without removal of the uterus. It was difficult to say what more could have been done, as there must have been severe haemorrhage through the bed of the myoma.

Dr. GIBBON FITZGIBBON thought that the position of the tumour and its size made the case similar to that of full-term ectopic pregnancy. He had recently seen a case of this, and had done exactly the same as Dr. Cannon. When the patient left the operating table he was very satisfied with her, but she died later, and he thought the cause of death was venous bleeding from the parametrium. When a patient came round from an anaesthetic, and venous oozing of blood started, it was frequently the cause of

death. In a case such as Dr. Cannon's he would certainly have saved the uterus.

Dr. LOUIS CASSIDY did not agree that it was wise to leave the uterus behind in this case. In patients who had a tumour of this nature he thought that the probabilities of pregnancy after removal of the tumour were extremely small. He mentioned the importance of testing the patency of the tubes before opening the abdomen, since unless the tubes were patent pregnancy could not take place. He thought that trusting to the closing of the bed of the tumour had proved to be ill founded. He would have performed complete hysterectomy in this case. If the tubes were not patent, the only reason for leaving the uterus was to preserve the menses. Myomectomy was quite a safe operation, but should be preceded by testing the tubes.

Dr. BETHEL SOLOMONS said that in such a case it was impossible to say whether hysterectomy or myomectomy should have been performed without being present. When there was reasonable doubt at the time of operation, hysterectomy was preferable in spite of the wish of the patient that the uterus should be preserved. Many myomas were infected, and this must be borne in mind when considering the question of radical or palliative measures. Secondary haemorrhage was the cause of death in this case. Haemorrhage during the operation of myomectomy could be overcome by the use of Bonney's clamp and applying a ring forceps to the ovarian vessels; it would, however, have been impossible to use the former in this instance.

Dr. A. H. DAVIDSON believed that in a case of cervical myoma, where the cervix was elongated, this elongation would be a point against preserving the uterus. He doubted whether lengthening of the cervix was likely to be reduced after removal of the myoma. Dr. Schiller had stated that myomata were signs of ovarian disease, and that if the ovary of a woman who had myomata was transplanted into a woman who had not, myomata would grow in the uterus of this latter patient.

Dr. CANNON, replying, said that the view in Vienna was that sterility and fibroids were associated. After he had enucleated the tumour he could not see the uterus for a long time, and he then found that it was high up in the abdomen on the opposite side. It was difficult to know whether the uterus would remain hypertrophied after the operation or not. The patient had certainly died from secondary haemorrhage, and this haemorrhage was, he thought, due to ovarian dysfunction.

Hyperemesis Gravidarum.

Dr. LOUIS CASSIDY read a report on three cases of hyperemesis gravidarum. He said that vomiting in pregnancy must be distinguished from affections of the gastro-intestinal tract, uraemia, tumours of the brain or spinal cord, meningitis, and latent pyelitis, and from symptoms of some other toxaemia of pregnancy, such as pre-eclampsia. The term must be reserved for those cases where vomiting and pregnancy were synchronous and where no associated cause other than pregnancy existed to account for the vomiting. Statistics of the occurrence of morning sickness were given to show that it was more frequent in primiparae than in multiparae; it occurred between the eighth and sixteenth weeks. He suggested that it affected those carrying a male rather than a female child. He quoted Lindemann's *post-mortem* findings and Miller's work in connexion with vagus control as it affected reflex cases. The psychical nature of some cases was stressed, but as against this it was shown that dogs and cats suffered from a similar affection in pregnancy. Blame had been laid at the door of the endocrine system, and some authors (principally French) had mentioned deficiency in the corpus luteum, which organ was supposed to counteract the toxins generated by the chorionic villi. The occurrence of hyperemesis in conjunction with vesicular mole was as high as 19 in 27 cases, according to Pinard. Van den Bergh's test for bilirubin in the blood had, in the hands of Seitz, shown increase in the case of hyperemesis over and above the normal increase during pregnancy. In those cases of neurotic or reflex origin the clinical picture was intense thirst, bodily weakness, and emaciation; these, though distressing to the patient, gave no real cause for alarm, and disappeared as pregnancy advanced. In the toxic variety, on the other hand, the pulse rate was increased in spite of rest in bed; the tongue was furred and dry; the skin was dry; the urine was diminished in quantity, and contained pathological elements such as albumin, casts, acetone; coma, delirium, and insomnia might occur, and the condition was very grave. Clinical notes of three patients treated within the past twelve months were given, each of whom recovered, though treated on different lines.

The PRESIDENT referred to a discussion on hyperemesis in early pregnancy at the Obstetrical Section in the previous year, and to the fact that Dr. FitzGibbon had then laid great stress on the neurotic element in these cases, and their treatment by psychotherapy. Very many of these cases were probably toxic in origin. The President had tried the administration of thyroid extract in two cases, but had not found it of any value. He was interested to note that in one case mentioned by Dr. Cassidy the use of corpus luteum had not been beneficial, though the injection of the patient's own blood had been effective; in another case potassium bromide had brought about cure. It was always taught that if starvation, thorough elimination, and rectal enemata did not stop the vomiting in these cases that pregnancy should be ended; yet Dr. Cassidy's three patients had been treated in different ways, and it had not been necessary to stop pregnancy in any of them.

Dr. BETHEL SOLOMONS said that if women were unaware that vomiting occurred in pregnancy few would suffer from it. Patients were often in doubt as to their condition, because they had been told by their friends that they ought to vomit, and this symptom was absent. He was a firm believer in the neurotic or psychological element as an etiological factor in the mild and severe forms of vomiting. Irrigation of the stomach had a good effect in all; when performed gently it caused no shock, and it had the excellent effect of removing the backflow from the liver and of curing hysterical patients because of its unpleasantness. Another advantage was that purgatives could be left in the stomach. He believed also in the value of removing such things as basins from the patient's bedside, and in putting the patient on a full diet free from all fats. While holding the view that most patients were of the psychological type, he admitted that there were a few who were toxaemic and must be treated as such. The need to perform therapeutic abortion seldom arose.

Dr. GIBBON FITZGIBBON thought the psychical element in these cases was very strong. Patients fell into the habit of vomiting, and therefore thought they should vomit. He had found, while Master of the Rotunda Hospital, that patients generally responded to starvation, elimination, and enemata, and he had had to induce abortion in only two cases. In one case, even after abortion, the patient had died. These cases seemed to him to respond to all sorts of treatment, and the more he saw of them the more he was convinced of the psychical element in them. In some cases there was reflex vomiting; sometimes, in cases of retroverted uterus, after the uterus was put back the vomiting ceased. Some patients suffered from excessive salivation, as well as vomiting. He did not think that there was any reason at all for believing in the toxic element in these cases. Vomiting was always more severe in multiparae than in primiparae. In one case he had tried injecting human blood into the patient, but without any result. He thought there was far too much fear of letting these patients carry on, and that pregnancy should be allowed to continue up to the fourteenth or sixteenth week; different methods of treatment should be tried till then to stop the vomiting before abortion was induced.

Dr. D. CANNON asked if any effort had been made by gynaecologists to visualize the mechanism of the stomach in these cases. He had seen two cases which had been investigated on these lines; it had been proved that achlorhydria was present, and that there was not much hydrochloric acid in the stomach. He referred to work by Professor Wilkie in this connexion, and also to a German investigator, who had shown that over-regurgitation of bile into the stomach would cause morning vomiting and other symptoms in these cases, and who suggested the administration

of atropine sulphate. He considered these cases functional in nature, and not toxic. He wondered how a retroverted uterus could cause gastric symptoms, and yet he had often found that simple correction of the uterus did effect a cure in these cases. An American investigator had also proved that duodenal stasis was present.

Dr. G. TIERNEY thought it was very difficult to decide which cases were toxic in origin and which were not. He considered that a number of these cases were associated with a psychic element, as well as with a toxic element. He mentioned a paper recently published by Dr. Leavy of New Orleans, in which it was stated as evidence of toxaemia that acetone was found in the urine, and diminution in the blood sugar and in the CO_2 combining power of the blood. He reported six cases in or about the fourth month of pregnancy. After ineffective treatment on general lines he had treated them with insulin and glucose. One patient who was four months pregnant, and had been vomiting continuously for three weeks, was in such a state that he thought he would have to resort to therapeutic abortion, but after the intravenous injection of insulin and glucose the vomiting ceased, and she went on to full term. The glucose was given in a 10 per cent. solution intravenously.

Dr. E. HARVEY believed that in the cases which were helped by insulin acidosis had been the cause of the vomiting, and therefore insulin would cure them; he did not think that it would necessarily work in other cases in which acidosis was not the cause of the vomiting.

Dr. CASSIDY, replying, did not think the psychical effect of washing out the stomach in these cases would be sufficient to justify the distress which it would cause to patients. Most of these patients were of a neurotic type. In most cases vomiting developed about the eighth week, and improved about the sixteenth week. It seemed to him that as the resisting powers of the body were increased the vomiting ceased. In any case of starvation acetone would be found in the urine, and therefore he did not think that finding it should be taken as pathognomonic of hyperemesis gravidarum. An increase of bilirubin in the serum was, he thought, a sign that the case might be toxic. From the clinical point of view it seemed to him that the important thing was to distinguish between the toxaemic and the purely neurotic case.

MEDICAL ASPECTS OF THE MATERNAL INSTINCT.

AT a meeting of the London Association of the Medical Women's Federation, held on February 22nd, at the British Medical Association House, with Miss E. BOLTON, the President, in the chair, Dr. ELIZABETH CASSON read a paper on maternal instinct in medicine.

Dr. Casson suggested that, while the immense strides made in neurology by the careful observations of facts and their subsequent study were frequently acknowledged, the study of instinctive behaviour was considerably neglected in medicine. Just as in the spinal cord, medulla, and mid-brain certain tracts were laid down in every individual, so certain definite instinctive responses to set stimuli would occur. Although it was not yet known exactly in what area of the brain these neuronic patterns were prepared, yet it seemed certain that they were as definitely laid to develop at various stages in the life of the animal as were the rubro-spinal and pyramidal tracts. A low-grade mental defective had no instinct for obtaining food, no curiosity, and no sense of fear, and had, in consequence, to be cared for as an infant all his life; but the normal infant developed all these instinctive reactions at the right time, and as he grew up, and during his whole life, every activity depended on these same primitive instinctive reactions common to all members of the human race, and, to a large extent, to all mammals. To the modern psychologist the play of primitive instinctive reactions was as unceasing in every activity as was that of the nerves governing the limbs. In every instance of behaviour, normal or abnormal, primitive instinct was demonstrable, and its recognition and study was necessary for diagnosis and subsequent treatment of any abnormal behaviour. McDougall had pointed out that certain unmistakable specific primary emotions could be observed in animals. They were best classified according to the three great ends of the life force—self preservation, race preservation, and the herd instinct. There were also certain other instinctive reactions with less specific ends. These were anger, aroused when any instinct was thwarted; curiosity, with its impulse to investigate anything outside the previous experience of the subject, which formed the basis of all intellectual development and provided the impulse for all research; joy, felt when any instinct was gratified; and grief, when any instinct had failed in its gratification. The best exposition of the parental instinct was that given by McDougall.

Discussing what was meant by the maternal instinct, Dr. Casson remarked that there were three processes in every reaction occurring in the nervous system—stimulus, appreciation, and either action or a strong impulse to action. The appreciation usually showed itself in what was called emotion. The stimulus and the resulting action might vary according to the experience and mental make-up of the individual, but the emotion—for example, of fear—was specific and unmistakable. The emotion specific to the maternal instinct was a yearning to cherish. There was unfortunately no word for it, but it would be heard expressed as an inarticulate sound by the women in a cinema audience when a child suddenly appeared on the screen. The mental patient, whether neurotic or psychotic, was to a physician in the position of a child, and provided a stimulus to the parental instinct. This might be the basis of the resentment felt by the doctor at the slightest interference with his or her treatment. Who had not met the angry parent, when someone suggested that she might bring up her child differently? In suggesting the maternal instinct as a subject for research there were a few points to be noticed—the age at which it appeared, its physical basis, its abnormalities, its relation to infanticide, its absence in advanced states of dementia. Sometimes the return of affection and pity for fellow sufferers or nurses was the first sign of recovery in mental patients. It was not easy to provide suitable stimuli for the maternal instinct in a mental hospital. Babies were scarce, and except for fellow patients there was no one to mother. Dogs and cats were the best substitutes. Where they could not be persuaded to mother people, patients might be able to express the allied instinct of nest-building and home-making in crafts and other branches of occupational therapy. An instinct might be abnormal in its unusual strength—for example, in cranks who kept twenty cats or pestered their friends for subscriptions to antivivisection societies. It might be aroused by an abnormal stimulus, or express itself unusually—Mrs. Jellyby (in *Bleak House*) was a notable example. A patient who had lost a baby, or had been nursing some other relative who had died, might thereafter lavish upon herself all the care and attention she had been giving to the child. Sometimes when the instinct was unsatisfied or repressed, the patients lost all touch with reality: they had babies in fantasy; in a mental hospital one might find an old dement gently nursing a pillow. One of Dr. Casson's patients, who had been aggressive, noisy, and abusive, became a different person after she was given a doll.

The outcome of Dr. Casson's experience was that, while it was not a waste of time to investigate blood pressure and knee-jerks, it was equally worth while to investigate the primitive instincts. If a doctor had been called in to discover early that the instincts of sleep and taking food were deranged in the puerperal cases investigated so carefully later at Broadmoor, then the babies would not have been killed by their insane mothers. If investigations were made of the maternal instincts of disgruntled women patients, much would be discovered. The profession was willing to supply artificial limbs; it might equally well be their job to supply an artificial baby. The maternal instinct was at least as strong as the mating instinct in most women, and the doctors must be on the look-out for its repression or wrong expression. Some women realized their need and knew why they were fretting.

Others did not know what was wrong with them, and did not realize that they needed the natural outlet of devoted service. They were the kind who kept well by doing war work and collapsed when they were left without it. For them a cure must be found; they must be persuaded to adopt a child, or guided into teaching, nursing, police, infant welfare work, management of working-class houses, or even into politics. By this means a selfish, self-centred, miserable woman might sometimes be transformed into a happy, useful citizen.

PATENT VENTRICULAR SEPTUM.

A CLINICAL meeting of the Devon and Exeter Medico-Chirurgical Society was held on March 17th, the President, Mr. A. L. CANDLER, being in the chair.

Dr. F. A. ROPER showed a boy, aged 9, admitted to hospital complaining of shortness of breath; it was stated that he had been "born with a bad heart." The apex beat was in the mammary line in the fifth space; there was a well marked systolic thrill and a loud to-and-fro precordial murmur. The pulse rate was regular at 90, and the blood pressure was 124/52. There was no cyanosis.

Dr. T. R. WHIPHAM said that from the point of view of diagnosis the more such cases were studied the more difficult the interpretation seemed to be. In the present case patency of the ductus arteriosus appeared to be the more probable solution. He based his opinion upon the intensification of the murmurs in the pulmonary area, but said that a previous patient with similar signs had entirely misled him, owing to the fact that the diagnosis was made during the first of two separate residences in hospital when the temperature was afebrile throughout, in contrast with the second period in hospital, when a high temperature and other constitutional phenomena were present. Eventually the case proved to be one of infective endocarditis. The *post-mortem* examination had revealed a clot in the pulmonary artery, but no congenital lesion.

Dr. G. L. THORNTON called attention to the wide disparity in the readings of the systolic and diastolic blood pressures, and asked Dr. Roper if this could be reconciled with a diagnosis of patent ductus arteriosus.

Dr. ROPER replied that he would hesitate before making a diagnosis of patent ductus arteriosus on the grounds that there was no cyanosis; there was no polycythaemia as evidenced by the blood count; the murmurs were spaced rather than appearing as one continuous rumble; there was wide separation of the blood-pressure readings. He suggested that patency of the ventricular septum was the most probable diagnosis.

Syringomyelia.

Dr. R. N. CRAIG showed a case of syringomyelia in a boy, aged 16, with a history of loss of power in both thumbs for some months. Then followed difficulty in holding things and in appreciating heat and cold. There was well marked wasting of the small muscles of both thumbs and the interossei of both hands, which were cold and cyanosed. No other neurological signs were present, and the diagnosis lay between syringomyelia and juvenile progressive muscular atrophy.

Dr. T. R. WHIPHAM did not consider that the tests for heat and cold were sufficiently conclusive in this case to warrant a diagnosis of syringomyelia. The signs present would, in his opinion, fit in quite well with juvenile progressing muscular atrophy.

Dr. F. A. ROPER considered that the juvenile type of progressive muscular atrophy occurring in the hands must be very rare, if not altogether unknown. He had also observed scars on the fingers which might well be attributed to blistering of the skin.

Dr. R. N. CRAIG remarked that there was absence of fibrillary muscular twitching, but did not agree that the age made the diagnosis of progressive muscular atrophy impossible. In addition to the signs already mentioned the boy had a definite scoliosis, which was so often found in association with syringomyelia.

Cerebral Embolism Secondary to Mitral Stenosis.

Dr. CRAIG showed also a boy, aged 16, with cerebral embolism secondary to mitral stenosis, who gave no history of rheumatic fever or other febrile complaint. Two and a half years ago he "fainted" and was unconscious for thirty-six hours; on recovery of consciousness he was found to have paralysis of the right arm and leg. This had gradually cleared up, but there remained wasting of the small muscles of the thumb, and to a lesser extent of the interossei of the right hand. There had been no change in sensation. Examination of the heart showed a characteristic thrill and murmur. The embolus was probably auricular in origin.

Other Clinical Cases.

Mr. G. P. HAWKER showed a middle-aged man with paresis of the right seventh, sixth, and third nerves. There was a fortnight's history of diplopia, and ptosis had been present for a week. Six weeks previously he had complained of pain over the right side of his face, but there was no record of any rash, vomiting, headache, or catarrh of the upper respiratory tract. The pupils were equal, but sluggish in their reaction to light; accommodation was normal. The movements of the right eyeball were very deficient, and of the left unimpaired. Both fundi were normal. The knee-jerks were exaggerated, but there was no inco-ordination or Rombergism.

Dr. CRAIG suggested treatment by a combination of iodides and mercury by the mouth, and neosalvarsan by injection, if a syphilitic diagnosis was established. Mr. HAWKER said he had found potassium iodide and mercury by mouth only, to answer well in similar affections.

Mr. R. WAYLAND SMITH showed, on behalf of Mr. DYBALL, a young unmarried woman with an enlarged submaxillary gland of several months' duration. The swelling varied in size from time to time, but not in relation to meals. The subjective symptoms were slight. The PRESIDENT remarked upon the difficulty in discriminating between an enlarged submaxillary salivary gland and an enlarged lymphatic gland beneath the jaw, and quoted a case where calculi were found on incision of what had seemed to be an inflamed lymphatic gland. Dr. SHAW had seen an obscure case where the correct diagnosis eventually proved to be endothelioma of the salivary gland.

Mr. NORMAN LOCK and Dr. MILLER MUIR showed a woman, aged 68, with atrophic scirrhus of the right breast of some seven or eight years' duration. There was a small lump in the left breast also. In spite of the extensive ulceration of the right breast, there was but slight invasion of the axilla. The patient was being treated by deep *x*-ray exposure. Dr. SHAW inquired if there was any risk of the *x*-ray treatment lighting up the growth. Dr. MILLER MUIR did not think there was any danger as regards stimulating the carcinoma, and he considered that the prognosis was hopeful with continued *x*-ray treatment, the surface being maintained aseptic and the growth at bay.

Mr. NORMAN LOCK showed a girl, aged 6, with ischaemic contraction of the left leg and scleroderma of the arm. The condition was first noticed after whooping-cough in the autumn of 1925; there was no complaint of pain. On admission to hospital the knee was stiff and swollen; there was three-quarters of an inch wasting of the left calf and slight wasting in the thigh also, the muscles of the latter being hard and stiff. There was scleroderma of the right side of the abdomen. Mr. Lock had exposed the external iliac artery, which was found to be very small; the periarterial coat was injected with absolute alcohol. The left arm had become affected last December. The patient was now being treated with radiant heat. Dr. R. N. CRAIG suggested a lesion of the suprarenals as a possible cause. The PRESIDENT commented on the small size of the artery, and said that sometimes it was wise in such cases to ligature the vein coincidently, thus avoiding a reflux through the venous channels. Mr. LOCK thought that the injections of alcohol had resulted in raising the temperature; he suggested a sympathetic cause. Nothing was found to support the possibility of a tumour or lesion of the spinal cord being responsible.

Mr. R. WAYLAND SMITH showed a case of uterine fibroid undergoing mucoid degeneration in a spinster, aged 49, who had suffered from haemorrhage but not dysmenorrhœa. When first seen there was a hypogastric tumour of the size of a five months pregnancy. Eventually the tumour, weighing 5½ lb., was removed, there being considerable oedema in the left broad ligament.

Mr. Wayland Smith showed also a man, aged 56, with osteo-arthritis of the left hip and spondylitis of the cervical and lumbar regions of the spine. Dental treatment, massage, radiant heat, and iodolysin had all proved futile, but marked improvement in movement and relief of pain had followed ultra-violet radiation. Dr. MILLER MUIR stated that, although structurally no improvement could be seen by radiographic examination, yet undoubtedly the symptoms of inflammation had been relieved. Careful dosing of ultra-violet rays was necessary, since otherwise this treatment might actually increase the pain. Mr. WAYLAND SMITH said that benefit had been noticeable after three weeks' treatment.

The PRESIDENT exhibited a fibrosarcoma of the mesentery from a man aged 68. The growth caused intestinal obstruction of a chronic type and was found to arise from the mesentery of the ileum, the mesenteric vessels being thrombosed, and the gut of a plum colour. The President showed also, with Dr. ADDINGTON DATE, a right testicle—becoming gangrenous from torsion—which had been removed from a man aged 52. He was first seen forty-eight hours from the apparent onset and in great pain; the scrotum was red, but the testicle was not enlarged.

THE INCIDENCE OF PNEUMONIA.

AT a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine held on March 25th, with the President, Dr. S. MONCKTON COPEMAN, F.R.S., in the chair, Dr. W. STC. MCCLURE read a paper on the incidence of pneumonia.

Dr. McClure called attention to the heavy mortality due to pneumonia and bronchitis and the unfavourable contrast between the north and south of England in this respect. By means of statistical tables and charts he indicated the correlation between mortality from pneumonia and air temperature, and pointed out that the statistical relation between mortality from respiratory diseases and fogginess was not clear-cut. He referred to the importance of the occlusion of ultra-violet light, quite apart from obvious fogs, which was a disadvantage of many northern cities. Dr. McClure presented much statistical evidence to the effect that domestic overcrowding and overcrowding upon the unit of area were important etiological factors of pneumonia. In his opinion "every additional open space provided in our towns, every slum area demolished, whether large or small, every effort made to clear the centre of our cities and to rehouse under hygienic conditions, will tend to reduce the mortality from these diseases."

In the course of the subsequent discussion Sir WILLIAM HAMER commented upon the analogy between the present position and one of Sydenham's epidemic constitutions. Dr. M. GREENWOOD quoted evidence to the effect that the pneumonia of childhood and adult life, but not of old age, was highly correlated with indices of domestic overcrowding. Dr. G. C. TROTTER thought the importance of nursing, its provision in overcrowded areas, was very great. Other speakers emphasized the importance of habits of life and adequate housing.

JAMES MACKENZIE INSTITUTE.

The Normal Temperature and Pulse Rate.

DR. PATON, on March 8th, read a paper on the normal temperature and pulse. Referring to the common belief that 98.4° F. was the normal temperature of the body, he said that it was not generally appreciated that this figure represented the mean of continuous readings during the twenty-four hours. Morning and evening records, as taken clinically, so rarely reached this degree in health that a reading of 98.4° F. should be looked upon with suspicion. In his school work he recorded the temperature night and morning of any pupil who might possibly have been exposed to infection, and he isolated the child if 98.4° F. was reached, provided any other symptom of departure from health was detected. By this plan he had often segregated cases of the exanthemata before they had given rise to infection, epidemic outbreaks being thus averted. In support of the view that a temperature of 98.4° was rarely recorded in health, the lecturer exhibited charts from sixty-one healthy girls in whom the morning and evening temperatures had been recorded for sixteen days. The temperatures were taken orally with standard thermometers, and the actual observations made numbered 2,169. A reading of 98.4° F. or upwards was obtained only on 225 occasions. Ten of the girls examined did not reach 98.4° once during the sixteen days. This agreed with his clinical observation that a temperature of 98.4° was commonly an early sign of a disturbance of health. The level of temperature in convalescence from illness, usually regarded as subnormal, was the same as that exhibited by these healthy girls. As a result of his observation his considered opinion was that the normal temperature from the clinical point of view must be regarded as nearer 97.4° than 98.4°. He suggested that the most valuable guide in deciding whether a border-line temperature was a healthy phenomenon, or was due to the invasion of disease, was obtained by observation of the pulse. If this was increased in rate, or if respiratory arrhythmia was absent, a temperature of 98.4° could not be regarded as physiological. Charts were shown from cases of measles illustrating the fact that a rise of pulse rate usually accompanied, if it did not precede, the initial rise of temperature, and that an increase of rate persisted after the temperature had reached its natural level in convalescence. Occasionally, however, a rise of temperature might occur before the pulse rate was disturbed. He added that it was obvious from these facts that the increase of pulse rate was not due to the pyrexia alone, but that both were due to the presence of toxins. It would appear that the mechanism regulating cardiac action might be more sensitive to some of these toxins than were the processes regulating bodily heat.

Herpes Zoster.

In a communication to the Institute on March 15th, Dr. BRYSON described a series of cases of herpes zoster which had come under his observation during the past seven years. In contrast to Head's record of age incidence, he had found the condition more frequent in patients over 25. He had found no evidence of epidemicity or relation to chicken-pox. Pain was usually a marked symptom and increased in severity with the age of the patient. The pain might be referred to a position apart from the rash. In one of his cases the attack was heralded by severe pain on the radial side of the left forearm accompanied by hyperaesthesia, whilst the rash appeared on the chest over the distribution of the second and third dorsal nerves. The disease had many years ago arrested the attention of Sir James Mackenzie. The definite skin and nerve lesions with the associated sensation provided peculiar opportunities for the study of symptomatology. If the symptoms of herpes zoster could be accounted for we should be well on the way to explain all symptoms. The lecturer pointed out that all afferent pathways were the afferent tracts of reflexes having some other end-result than sensation; that sensation was the concomitant of a reflex, and that the reflex involved in the nerve lesion was probably a skin capillary reflex. The skin lesion occurred over papillae where the capillaries were most numerous. It was curious that tactile sensation was not interrupted considering the nature of the lesion. Anaesthesia was not a symptom; indeed, hyperaesthesia was usual. Dr. Bryson threw out the suggestion that pain arose on the same reflex to which the thermal sensations were concomitant, in all likelihood a vascular one. Hyperalgesia was due to an interaction occurring in the "neopallium" between the impulses of normal tactile sensation and those arriving from the site of a lesion, not, as has hitherto been represented, occurring in the cord.

THE AUSTRALASIAN MEDICAL CONGRESS
OF THE
BRITISH MEDICAL ASSOCIATION,
DUNEDIN, NEW ZEALAND.

(*Continued from page 587.*)

THE SCIENTIFIC SECTIONS.

THE scientific and clinical part of the Congress programme included meetings of the twelve Sections; fourteen joint meetings, in which several Sections combined; a special evening discussion on the mutual relations of the State, the hospitals, and general practitioners; and clinical demonstrations each morning from 8 to 9.30.

SECTION OF MEDICINE.

In addition to taking part in seven combined meetings, this Section devoted two sessions to renal and blood conditions respectively. In the first of these sessions Dr. W. RAY (South Australia) described an epidemic of streptococcal nephritis, and Dr. S. D. RHIND (New Zealand) discussed renal efficiency with reference to the value of the various tests. The biochemical tests in common use were not very satisfactory in medicine, but served to distinguish between functional and post-nephritic albuminuria, and to assist in regulating the diet in nephritis. In obstetrics they indicated the cases of albuminuria in which pregnancy had to be terminated, and in surgery the suitability for operation in urinary cases. The estimation of nitrogen in the saliva was an easy and rapidly completed experiment from which the blood nitrogen could be inferred with a high degree of accuracy.

Dr. J. V. J. DUHIG (Queensland) dealt with the subject of diet in renal disease.

Professor WITHERINGTON STUMP (New South Wales) demonstrated the process of blood formation. Microphotographs were shown to illustrate the production of white and of red blood corpuscles in the ends of developing long bones. The stages were shown from a syncytial arrangement to a differentiated cell, the nucleus of which underwent changes resulting in the appearance of the red and white cell series. The development of giant cells was also shown. The special cells of developing bone were contrasted with the blood elements.

Dr. D. E. FENWICK (New Zealand) outlined the existing speculations as to the cause of pernicious anaemia, with special reference to the part played by the achlorhydria. A cure could not be claimed unless there was a return of hydrochloric acid secretion, with assurance that it was not merely a prolonged remission. The merits of the different means of treatment were discussed—the administration of sufficient hydrochloric acid, the treatment of focal sepsis, the administration of arsenic, preferably by mouth, and blood transfusion as a means of tiding a patient over a critical period. He doubted the value of splenectomy, but he had had no personal experience of it.

Dr. D. W. CARMALT-JONES (New Zealand) regarded the treatment of pernicious anaemia by repeated blood transfusions of about ten ounces of suitable blood at intervals between two and four weeks, for six months if necessary, as a most important addition to ordinary arsenical medication. A patient who did not show marked and sustained improvement with this treatment was probably suffering from some disease other than pernicious anaemia.

SECTION OF SURGERY.

A discussion on the surgical aspects of goitre was opened by Mr. BASIL KILVINGTON (Victoria), the President of the Section. He said that the surgical treatment of goitres centred mainly around those enlargements associated with toxic symptoms; of these there were two main types—the exophthalmic and the hyperfunctioning adenomas. Toxic goitres, with the exception of very mild forms, had now become entirely a surgical problem; the results of medical treatment were unsatisfactory, since when rest and iodine were stopped the symptoms recurred. He had not seen any benefit from *x*-ray treatment, and thought that subsequent operation was rendered more difficult from fibrosis around the lobe. With proper precautions the operative risk in thyroid surgery was only about the same as that in other major surgical operations. There should be preliminary rest and treatment with iodine, the dose of which varied with the toxicity. The anaesthetic should be nitrous oxide and oxygen. Only in exceptional cases should an attempt be made to remove all the necessary thyroid tissue at one operation. A single lobectomy, though it improved the patient, was never sufficient. Often the patient was satisfied, but she should be urged to have further operation. Removal of a single lobe was always followed by a slow relapse of symptoms, and this might result some years after removal of most of the thyroid tissue. A small amount of thyroid tissue should be left; this should be the posterior strip of the lobes, which distribution minimized the risk of traction and damage to the recurrent laryngeals. An exception to removing more than one lobe was where a hyperfunctioning adenoma was single or, if multiple, the nodules were confined to one side.

Mr. H. C. TRUMBLE (Victoria) dealt with the value of observations of the basal metabolism in the surgical management of goitre. He said that the basal metabolic rate for any organism was the minimum rate of change which could be induced by the exclusion of factors which normally tended to speed up the metabolism. These factors were digestion, exercise, excitement, and menstruation. At the time of estimation of the metabolic rate the state of the subject should approach that attained in peaceful sleep some twelve hours after the last meal. Normally the basal metabolic rate, when properly estimated (and several estimations on different days might be necessary to arrive at a reliable reading), should fall within certain limits. The thyroid gland apparently produced a substance which, when present in the blood, had the property of augmenting the metabolism. In disease of the thyroid gland the secretion might be deficient, or absent, or increased above the normal level. When there was no thyroid secretion the basal metabolic rate fell to about 40 per cent. below normal, and the organism existed at a very low level, both mental and physico-chemical activity being depressed to an extreme degree. A persistent increase in the amount of thyroid activity produced the well known syndrome generally entitled exophthalmic goitre and toxic adenoma of the thyroid gland. The basal metabolic rate might be increased to 100 per cent. above normal. In many cases the diagnosis was not in doubt, and estimations of the basal metabolic rate might be regarded as a luxury. There were many border-line cases where the diagnosis was not clear, and here the accurate measurement of the vital change might establish the diagnosis and direct treatment.

Gastric and Duodenal Surgery.

Mr. H. B. DEVINE (Victoria) gave a very interesting paper on the status of gastro-enterostomy in gastric surgery, illustrated by a cinema demonstration. He compared the views of English surgeons who favoured gastro-enterostomy with those of the Continental surgeons who favoured partial gastrectomy in the treatment of gastric and duodenal

ulceration. In his own opinion the results of routine gastro-enterostomy for gastric and duodenal ulcer were not satisfactory because the operation did not generally lead to the healing of the ulcer, gastro-jejunal ulcers were not a very unusual complication of the operation, and haemorrhage from an unhealed ulcer was fairly frequent. His criticism of the sanguine view of gastro-enterostomy results was that the surgeon often regarded a case as a perfect cure, whereas the patient felt that the operation had been a miserable failure because since his operation he had become afflicted with a train of very unpleasant nauseating but obscure symptoms almost worse than those of the original ulcer. These symptoms, regarded by the surgeon as neurasthenic or negligible, were very real, for when the "successful" gastro-enterostomy was undone the patient was delighted with the relief obtained. It was only fair to point out that the advocates of gastro-enterostomy contended that in such cases the patients had not been properly selected, and there had been an absence of the requisite knowledge of physiology and pathology, and the operative judgement, skill, and precision which were demanded in this operation almost more than in any other. In his view the curative action of gastro-enterostomy depended almost entirely on its effect on the mechanism of retention of the stomach—namely, on its emptying time. It depended also, but to a lesser extent, on the increase of alkaline regurgitation, but this to a large degree went *pari passu* with the emptying time, so that the fundamental physiological aim in gastro-enterostomy was to regulate this evacuation. The emptying time depended upon the "gradient" of the stomach and intestine, and possibly also upon the distance of the stomach from the pylorus. He distinguished two kinds of duodenal ulcer. The very chronic "acid-produced ulcer" occurred in sthenic persons, and was perhaps exclusively due to a very high acidity, the result of disordered gastric physiology. It was the same sort of ulcer as Mann had produced in his experimental dogs. The less chronic "debility ulcer," in which a lowering of resistance played the principal part, was comparable with the experimental ulcer that Rosenow had produced by infection. Mr. Devine thought that in gastric ulcer the acidity was of less importance; gastric stasis and depression of tissue resistance from local or general causes played the major part. In the application of gastro-enterostomy for the cure of ulcer there were two fundamental considerations: the abnormal physiological and pathological conditions which produced the ulcer, and the gross degenerative tissue changes brought about by prolonged secondary infection in the chronic ulcer. These fibrous changes and local devascularization would preclude the healing of an ulcer even in the absence of acid and even under the most favourable physiological conditions which an ideal gastro-enterostomy could give. Of unsuccessful gastro-enterostomies in his own clinic 14 per cent. were due to ulcer formation and 10 per cent. to gastric motility errors. The gastric motility patient was completely relieved of the symptoms of ulcer, but as a direct effect of the gastro-enterostomy he suffered from most distressing symptoms after meals, such as nausea, sinking sensation, vomiting, and, in addition, from diarrhoea with copious "explosive" motions and from great loss of weight and energy. Other errors of motility were attributable to excessive spur formation at the anastomosis, or to twisting in its long axis of a too long or too short afferent loop. Mr. Devine's investigations had led him to believe that an error in gastric or intestinal motility was the fundamental basis of even the "high acidity failures." With regard to his technique in gastro-enterostomy, the following points differed from the usual practice: collapsing the stomach with an air-pump to get in the undistorted stomach the proper point for the stoma; the stoma was curved to get some intestinal regurgitation; he did not use clamps, but prevented leakage by using the electric air-pump aspirator: a three-layer anastomosis with catgut was made. He recommended the following post-operative measures: an x-ray determination of the emptying time; a fractional meal to ascertain reduction of acidity; written instructions to the patient as regards diet.

Mr. ST. JOHN W. DANSEY (New South Wales), discussing the acute perforation of gastric and duodenal ulcers, said that there was probably no condition in surgery where successful treatment depended more on early diagnosis and prompt operation than acute perforation of gastric and duodenal ulcers. In figures taken from the records of the Royal Prince Alfred Hospital for the last ten years, perforation of gastric ulcers occurred in 39 males and 12 females, and of duodenal ulcers in 91 males and 7 females. Perforation of an acute ulcer of the stomach and duodenum hardly ever occurred. The investigation of all gastric ulcers operated on at this hospital during the last ten years showed that the anterior situation was more common in the male in the proportion of four to one. The average age for perforation of a gastric ulcer was 41 years, and for the duodenal between 40 and 49. Acute perforation of malignant ulceration occurred only once in this series of 149 ruptured gastric and duodenal ulcers. After the chronic ulcer had reached the peritoneum, the exciting cause of the rupture might be physical exertion or the powerful contractions of the stomach associated with hunger pain. The treatment of ruptured gastric and duodenal ulcers was essentially surgical. Under medical treatment the mortality was said to be 95 per cent. The abdomen was opened through the linea alba above the umbilicus. The perforation was closed by three mattress sutures of chromic gut. A posterior gastro-enterostomy was performed, except where the condition of the patient was very bad. Clamps were not used. Among fifteen cases of perforation of gastric ulcer treated by closure of the perforation and gastro-enterostomy there was only one death, and no death occurred among forty-one cases of duodenal ulcer.

Genito-urinary Surgery.

The surgery of the epithelial bladder tumours was the subject of a joint paper by Mr. GORDON CRAIG and Mr. R. K. LEE BROWN (Sydney). Tumours of the bladder had been recognized as early as 1551, but no treatment had been thought possible until Sir Henry Thompson, in 1880, removed successfully a growth through a medial perineal cystotomy. French surgeons introduced the thermo-cautery, and later the operating cystoscope was developed. High-frequency currents were first used by Edwin Beer of New York in 1910. The value of radium and *x* rays in this connexion was still uncertain. All epithelial bladder growths were to be considered malignant. Men were more liable than women in the proportion of four to one; infants were never attacked. A few cases in children had been recorded, but the incidence began definitely after the age of 20; it increased in each decade up to the sixties, from which time it declined. In Broders's classification of malignant growths of the bladder into four groups the malignancy was assessed on the proportion of the differentiated cells resembling bladder epithelium to the undifferentiated irregular cells with prominent nucleoli. In most cases of the lesser degrees of malignancy painless terminal haematuria was the first sign of the disease; it was due to portions of the growth being caught in the vesical sphincter at the end of micturition. Large growths were crushed by the bladder contraction and so the urine was never free from blood. With a greater degree of malignancy the tumour might be fairly advanced before blood appeared in the urine. In the less malignant cases surgery held out good hope of cure, though repeated examinations were necessary during the subsequent five years. Small papillomatous growths could be dealt with by diathermy through the cystoscope, except when situated around the vesical neck in men. The more malignant sessile growths gave very poor response to surgical treatment, and diathermy was preferable.

Mr. S. H. HARRIS (New South Wales) gave a cinematograph demonstration of prostatectomy.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

At the first session the President of the Section, Dr. J. W. DUNBAR HOOPER (Victoria), delivered an address on the present position of obstetrics and gynaecology. He was followed by Dr. C. F. MORKANE (New Zealand), who contributed some observations on Rubin's transuterine insufflation. The second session was devoted to a discussion of the problems of Caesarean section. This occupied both

morning and afternoon, and included a paper by Dr. H. JELLETT (New Zealand) on the abuse of Cæsarean section. Professor J. C. WINDEYER (New South Wales) read a paper entitled "The trial labour," and Dr. A. BONAR LINDSAY (New Zealand) discussed pubiotomy. On the following day a cinematograph demonstration of uterine prolapse was given by Dr. NORMAN McARTHUR (Victoria), and Dr. CONSTANCE ELLIS (Victoria) described work in connexion with venereal diseases. On the last day a paper on pelvic lymphangitis was read by Dr. H. H. SCHLINK (New South Wales); in the afternoon a discussion on puerperal sepsis was held, and Dr. MARY DE GARIS (Victoria) read a paper on uterine inertia.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

Dr. C. H. KELLAWAY (Victoria) read a paper on ascending renal infection. He said that the general trend of modern opinion was to regard nearly all renal infection as blood-borne, and in a number of cases the evidence did not admit of any other interpretation. If the bladder innervation was deranged, or if there was mechanical obstruction to the outflow, ascending infection might occur either by lymphatics or along the lumen of the ureter. He described the work of many who had attempted to prove ascending infection, but all this work was inadequately controlled in regard to the possibility of blood infection. His experiments had been performed on guinea-pigs, rabbits, and cats in which partial obstruction of the urethra or disorganization of the nervous mechanism of micturition had been produced. In guinea-pigs micro-organisms were introduced into the bladder, while in other experiments suspensions of "oil-blue" were used. In some of the experiments on rabbits and cats carmine and lamp-black suspensions were used, but later lycopodium suspensions were found to be the most efficient. He described his experiments in detail, and said that it was clear that in cats and rabbits the conditions upon which ascent along the lumen depended were very different from those which obtained in the guinea-pig, in which ascent readily occurred if the nervous mechanism was disorganized. The ascent of organisms was regularly demonstrable in their experiments. With regard to the lymphatics, his experiments with carmine were strongly opposed to the view that ascent in guinea-pigs could be explained in this way, since the particles were invariably found in the lumen of the ureter and pelvis and never in the wall of the ureter and its accompanying lymphatics.

Professor J. B. CLELAND (South Australia) contributed some considerations of the anæmias, leukæmias, leucosarcoma, and other allied conditions. He was unable to throw any further light on the etiology of pernicious anæmia. A high colour index with megalocytosis was diagnostic, the latter being the more important. Carcinoma of the stomach gave rise to an anæmia closely resembling pernicious anæmia. In 1923 a patient in Adelaide Hospital showed a typical blood picture of pernicious anæmia, and at necropsy a large gastric carcinoma was found. For many reasons this case was regarded as one of pernicious anæmia with independent gastric carcinoma. The association of achlorhydria with pernicious anæmia was well recognized, but in very few cases was free hydrochloric acid found. The hæmolytic anæmia of pregnancy was rare, and although it resembled pernicious anæmia closely it appeared to be quite distinct. Several patients had been treated in Adelaide for aplastic anæmia. He had found blood transfusion to be the most beneficial treatment. These anæmias were probably all of toxic origin. There were three views which might be taken as to the nature of leukæmia, taking lymphatic leukæmia as an example. The disease might be: (1) a hyperplasia of lymphoid tissue with eventually an overthrow of cells into the circulation, the result of a dyscrasia; (2) a hyperplasia of lymphoid tissue with overflow due to the stimulant action of some toxin or the establishment of a virus; (3) the leukæmias had been likened to malignant neoplasms, and it had been suggested that they actually did represent such arising in lymphatic tissues or from certain constituents of the bone marrow and spleen. There was, however, a kind of malignant condition—lymphosarcoma—the behaviour of which was quite unlike that of lymphatic leukæmia. He illustrated his remarks with case histories, and said, in conclusion, that he thought the leukæmia picture was only incidental to the disease, and not the essential characteristic.

Poliomyelitis.

Dr. C. M. HECTOR (New Zealand) read a paper on poliomyelitis, with special reference to the outbreak in New Zealand in 1924-25, experimental work at Otago Medical School, and the essential nature of the disease. He said that before the first epidemic in New Zealand in 1914 there had been scattered cases of poliomyelitis, but the second epidemic of 1916 was practically confined to the Wellington district of the North Island, the proportion of non-paralytic to paralytic cases being twelve to one. The 1924-25 epidemic was more extensive, affecting the warmer parts of the country more than the cooler; an account of it had appeared in the *Medical Journal of Australia*. In conjunction with the New Zealand Branch of the British Medical Association the Health Department had published a memorandum on diagnosis, and this, together with preventive measures, resulted in a low paralysis rate, though the case mortality was high. The virulence of the infection was found to increase when restrictive proceedings were imperfect. The percentage of non-paralytic cases increased towards the end of the epidemic, in consequence probably of the better recognition of pre-paralytic cases and the earlier administration of serum. Dr. Hector summarized the replies to the questionary issued by the Health Department in 1925. The average recovery rate of notified cases was found to be 84 per cent. Infection occurred chiefly from personal contact with patients or carriers; there was no evidence of insects being concerned or other intermediate agents. About 89 per cent. of the patients were under 16, and the average estimate of abortive cases was eight to one. No relation to social circumstances or population density was found. Human convalescent serum had proved to be a specific in promoting rapid recovery and in preventing paralysis if given in the pre-paralytic stage. Dr. Hector then described the experimental work in Dunedin, and said that attempts to inoculate monkeys and rabbits with the virus had failed, owing probably to its low virulence. Discussing the nature of poliomyelitis and its relation to allied diseases, he said that it appeared to be distinct from encephalitis lethargica, though the boundary lines were ill defined. He referred to Topley's work on the conditions governing the development of immunity in a limited herd, and to Dudley's discovery of the importance of crowding in relation to infection. Subminimal infective doses might accumulate until they exceeded the minimal infective dose; when they collected faster than the defensive mechanism could resist, disease ensued. With less velocity of infection immunity might be produced without there having been any obvious illness.

Dr. JEAN MCNAMARA (Victoria) and Dr. F. G. MORGAN (Victoria) described the collection of blood from human donors, the preparation of antipoliomyelitic serum, and the results of its employment in treatment.

Resistance to Tuberculosis.

Professor J. B. CLELAND (South Australia) described the tuberculous lesions found in 800 Australian necropsies. During recent years it had been the custom to record at the conclusion of every necropsy whether tuberculous lesions were present, together with full particulars of such lesions. In 800 records the results were: Number of tuberculous foci detected, 527 (66 per cent.); slight lesions present, possibly tuberculous, 43; tuberculous lesions present, 230 (28.7 per cent.); healed calcified tuberculous lesions, 103 (13 per cent.); small quiescent or healing lesions, 11; extensive pulmonary tuberculosis, 51; extensive tuberculosis elsewhere than in the lungs, 7; tuberculous meningitis, 6; miliary tuberculosis, 4; pulmonary lesions, slight or semi-quiescent, death due to other causes, 48. He concluded that tuberculous lesions were less frequent in Australia than in Europe. Nearly half the tuberculous lesions found were small and quite healed. Healed calcified tuberculous lesions of glands in the abdomen or thorax did not necessarily protect against fatal pulmonary

tuberculosis. There was in the community a natural tendency for the patient's tissues to surround and overcome the tubercle bacilli. There was a close resemblance between the nature of lesions due to tubercle bacilli and those due to toxic, non-immunity-producing, colloid silica particles. Tubercle bacilli, coal pigment, and silica particles must always be carried in fluid or in an ingesting cell. Rapid proliferation of firm connective tissue could close all avenues of escape to tubercle bacilli. If these processes could be accelerated the figures of "*healed calcified* lesions" would increase. Calcification occurred more readily in necrosed tuberculous foci than in necrosed silicolic ones. Extensive tuberculous lesions of the lungs did not prevent the successful inoculation by ingestion of the intestines. There was no evidence that the control of the tuberculous process had been due to an immunity response rather than to a fibrosis unrelated to immunity. Susceptibility to tuberculosis was probably due to the possession of a connective tissue which responded too slowly and too feebly to the presence of tubercle bacilli, so that these were carried further afield *before fibrosis could wall* them in.

Various Papers on Pathology.

Dr. C. H. KELLAWAY (Victoria) discussed the specific *localization of streptococci*. His experiments had related to the alteration in the cultural characteristics and specific localizing tendency of streptococci caused by repeated animal passage. He described fully his methods and results, and said that organisms which tended to localize in one tissue might have superadded a tendency to localize in another tissue, while their original localizing tendency remained unaffected.

Professor CLELAND read a paper contributed by Mr. L. B. BULL, D.V.Sc., on the value of comparative pathology in the problems of human disease. Advances in animal pathology had in the past, and would in the future, interact on and profoundly influence human pathology. Investigations of filterable viruses had included those associated with disease in lower animals. One virus which had been closely studied was that causing pleuropneumonia in cattle; Heslop had shown that there were at least two types of this virus present in Victoria. Systematic research into the toxaemias of pregnancy in sheep was very necessary, since it might throw much light on the causation of human disease. Inflation of the udder with air had proved very successful in treating "milk fever," which might possibly be associated with hypoglycaemia. *Lambs were subject to* dysentery of unknown origin, but recent work seemed to point to *B. welchii* as a possible causative factor. He referred to osteo-arthritis in lambs and dealt in some detail with botulism. Every accurate observation of a pathological process in an animal was of value in the study of human disease. This was illustrated by the report of a case of a form of conjunctival granuloma in horses which had been *fully investigated*; a case in a human subject had been subsequently detected.

Dr. E. F. D'ATH contributed a comparative study of the Kahn and Wassermann tests in 6,000 cases. As regards untreated patients there had been total agreement of the results of the two tests *in 5,369* cases and disagreement in 60 cases—an absolute agreement of 98.9 per cent. With patients under treatment there had been absolute agreement in 541 cases, relative agreement in 20, and disagreement in 70—an absolute agreement of 85.7 per cent., and a relative agreement of 88.9 per cent. The main advantages of the Kahn test were its *simplicity* and economy. The disadvantage was that the results were occasionally hard to read and still more difficult to interpret. From his results it would appear to give more false reactions than the *complement fixation test*. In the results obtained in cases under treatment the Kahn reaction became negative first in 41 cases and the Wassermann in 29 cases. He concluded by saying that the Kahn test was a reliable control to the complement fixation test. The latter was the more valuable, but to obtain the best results both tests should be used.

Dr. W. M. MOPPETT (New South Wales) described experiments with an *x*-ray spectrometer and the chorio-allantoic membrane of the chick embryo at eight to nine days' incubation. He had exposed areas of the allantois to small beams of *x* rays of known wave-lengths, scattering being reduced to a minimum. Further incubation for four days was necessary to develop the changes. Such conditions as atrophy, hypertrophy, epithelial invasion, leucocytosis, myxomatous changes, and the formation of fibrous tissue were observed. From his experiments he concluded that certain wave-lengths had the potential properties of affecting living tissues, these properties being antagonized by the presence of other wave-lengths. He added that the *wave-length and homogeneity of a primary beam of x rays* were very important factors.

SECTION OF PREVENTIVE MEDICINE AND TROPICAL HYGIENE.

This Section held three discussions on the school and administrative sides of the work of the public health nurse, epidemiology, and industrial hygiene. It took part in six combined meetings, and, in addition, various papers on special subjects were read.

The Public Health Nurse.

Dr. HARVEY SUTTON (New South Wales) dealt with the school aspects of this subject and said that the school nurse was a home or health visitor, whose duty was to "follow up" children found defective by the school medical examination, thus establishing a personal link with the home. She also visited the school before the doctor, testing the children's vision, and referring any child for medical examination. She also made a "clean survey" for pediculosis and impetigo, visiting and reporting on many homes. *Children notified were later inspected again.* This home visiting was independent of the doctor, and directly related to the head office. Occasionally she was called on to perform special duties, such as Schick-testing and vaccinating. To provide a closer control for infectious diseases and school epidemics more nurses were needed, and the pre-school children should be included under their care; Dr. Harvey Sutton showed how better control of infection would thus result. He outlined a scheme of training for the public health nurse; pre-graduate teaching to include experience in home visiting, district nursing, and in an infectious disease hospital, while the *post-graduate instruction should* consist of specialized work, such as infant and school health. He advocated the drawing up of a definite course for health nurses in Australia and New Zealand.

Dr. M. H. WATT (New Zealand) considered the matter from the point of view of administration. Public health, in the past limited to external sanitation, had now become personal in its application, attention being focused on the individual rather than on his environment. Under the new régime a new link, the public health nurse, was required, as the connecting link between the public health administrator and the home. The most important function of the public health nurse was to ensure the health and well-being of the mother during pregnancy, and of the child during infancy and the pre-school and school ages. Such duties were best performed by a *woman who* had had hospital and midwifery training, followed by a post-graduate course in preventive medicine. For organization he advocated the generalized system of public health *nursing, combining* preventive and curative nursing in restricted, and especially in rural, areas. Dr. Watt gave details of the public health nursing service of New Zealand at the present time.

Infectious Diseases.

Dr. MARY CHAMPTALOUGH (New Zealand) described her investigation with Dr. Baker McLaglan of the incidence of tuberculosis among school children. A group of 1,268 average children, between the ages of 5 and 15 years, in the Wellington and Canterbury districts, had been tested by the Moro percutaneous tuberculin method. Those giving positive reactions (14.1 per cent.) formed a selected group for further investigation by radiologists and chest specialists. Necropsies during the past ten years on children of this age period also *indicated 14.1* per cent. of tuberculous lesions in children dying from other causes. Including those whose deaths were due to tuberculosis, 28.2 per cent. showed lesions. The age incidence varied

with the locality, Canterbury giving a higher incidence in earlier years. Exposure to infection was found to have greater influence than family history. The test did not show that a proportion of children of subnormal nutrition had latent tuberculosis. Of the total group investigated, 9.15 per cent. had active disease, while 2.36 (or 16 per cent. of positive cases) had latent tuberculosis, which might under adverse conditions become an active lesion. These children were being kept under observation, and had been placed on suitable treatment.

Surgeon Commander S. F. DUDLEY, R.N., dealing with the possibility of forecasting outbreaks of diphtheria, said that the Schick test made it easy to determine whether any individual could contract clinical diphtheria when exposed to ordinary doses of the specific organisms. Thus immune and susceptible persons were distinguished—Schick negatives and positives respectively. Similarly a group of people could be considered immune or susceptible according as the percentage of immunes in the group was above or below a certain figure. The spread of parasitic infection depended, not only on the actual density of the susceptible hosts in an area, but also on the ratio which existed between them and the immune hosts in the same area. The Schick-positive percentage also gave the relative number of immunes to each susceptible. When the percentage of immunes was above a certain value, which would vary with every environment and every complex of host and parasite, the resistance of the herd to the spread of symptomatic infection became so high that epidemics were unable to start or continue, even when many susceptible hosts and infecting parasites remained in the environment. This degree of herd immunity, in the case of diphtheria, could be ascertained for certain population groups. Once ascertained Schick-testing would show when an epidemic was to be feared, when a diphtheria epidemic in progress might be expected to cease, and how many individuals in the community must be rendered immune to raise the resistance of the herd to a safe point.

Fatigue in Industry.

Dr. J. S. PURDY (Sydney) considered the question of fatigue in industry. He said that to attain maximum efficiency in industry it was necessary to prevent excessive fatigue beyond the point recoverable by a reasonable period of rest. He had noted the effect of two days' rest weekly, in contrast with one, or with one and a half days' holiday. By means of figures and graphs from Sydney statistics, he showed that where the forty-four hours week obtained, a small reduction in accident incidence followed, and a marked reduction in absence from work through sickness. Overtime, with its resultant over-fatigue, led to increased absence from work, due especially to neurasthenia; two days' rest weekly had resulted in less absence attributable to this cause.

SECTION OF NEUROLOGY AND PSYCHIATRY.

Four discussions were arranged by this Section, the subjects being: the physical basis of mental disorder, the social aspect of mental disorder, the university teaching of psychiatry, and the voluntary patient. At the end of the commencement of the first session, Dr. O. LATHAM (New South Wales) delivered his presidential address on the place of pathology in mental disorder. After some preliminary remarks on the history of the development of pathology in mental hospitals, Dr. Latham referred especially to the work of the late Sir Frederick Mott, the late Professor Kulchitsky, and the late Dr. R. G. Rows. Froude Flashman, after visiting the laboratories of France, Germany, and England, had established the first neurological laboratory in the southern hemisphere. The President then referred in some detail to the need of pathological research in the mental hospitals and the scope of the work; he outlined a course of pathology suitable for candidates who were proceeding to the diploma in psychiatry. He then dealt with the duties and uses of the central laboratory of the mental hospitals. There was a great field for research in the changes that resulted in the nervous system from various forms of poisoning, and the work of Hunter and Royle had greatly stimulated interest in the sympathetic system. Some of the histological work of these two investigators had been carried on in Dr. Latham's laboratory. More attention ought to be given to the basal ganglia, both in connexion with encephalitis lethargica and its sequels, and also to disseminated sclerosis. Dr. Latham concluded that the duties of the pathologist were to aid the psychiatrist in his problems and to help the psychologist to realize how much mental function depended on neuronic activity by providing as many clearly defined pathological specimens as possible, together with histories accurately recording the mental states associated therewith, at the same time respecting the conception of a mental trauma.

The Physical Causes of Mental Disorders.

Dr. G. P. N. PRIOR and Dr. A. L. KINNA (Sydney), in a joint communication, referred to the effects on the mind of physical illness, neoplasms in the cranium, and drugs such as alcohol and opium. They quoted their own experience in the relation of septic foci to mental disorder. By eradicating the foci of infection and administering autogenous vaccines they had obtained good results. They also gave details of cases treated successfully by endocrine therapy, in which the mental disorder seemed to depend on endocrine dysfunction.

Dr. J. BOSTOCK (New South Wales) discussed the "composite" viewpoint in relation to the causation of mental disorder, with particular reference to sepsis and endocrine derangement. He referred to the work of H. H. Cotton and quoted some of his own cases which seemed to support Cotton's view, but an experiment on twenty-five cases of dementia praecox with Plombière douching produced negative results, and his own experience in the main could not support Cotton's results. His attention had then been turned to endocrinology, 40 per cent. of cases in one series showing thyroid deficiency, and he had been led to the hypothesis that thyroid secretion was necessary for the proper functioning of the vagal nucleus, and that possibly this combination also included the thalamus (as the seat of the emotions), giving a thalamo-thyro-vagal balance. Such a conception would account for the fact that in an individual psychosis there might be at the same time changes in the emotions, thyroid gland, digestive system, and circulatory system, together with an obscure reaction to thyroid administration owing to the variety of factors involved, while sepsis might also exist owing to change in digestive system, and accompanied by the presence of indicanuria and intestinal stasis.

Dr. H. M. NORTH (New South Wales) confined his remarks to the "focal sepsis" side of the subject. He reviewed the work of H. H. Cotton, and said that his claims were extravagant and could not be supported by the facts. A carefully controlled experiment by Kopaloff and Kirby failed to show any relation between focal sepsis and the functional psychoses. Dr. North was more in favour of the existence of a specific toxin from a specific organism causing a specific lesion, as in the case of encephalitis lethargica. From his own experience he concluded that patients had received too much surgical attention.

Dr. S. J. MINOGUE (New South Wales) referred to the fact that, though many of the patients suffering from functional psychoses showed evidences of endocrine disturbance, the results of endocrine therapy were very disappointing. The search for the basic factor must be extended further than endocrine disorders. He said that Cotton's dogmatic assertion that focal sepsis was at the bottom of all mental disease could not be established by the evidence adduced in support of it. The riddle of psychosis was still unsolved and the treatment remained empirical and symptomatic.

The Voluntary Boarder System in Mental Hospitals.

Dr. E. JONES (Victoria) quoted from a report of the British Royal Commission on Lunacy and Mental Disorders (1926), and outlined the differences between the British

and Australasian procedure, giving figures to show to what extent the system was in use in Great Britain, Victoria, New South Wales, and New Zealand. He considered that rather more than 50 per cent. of the voluntary boarders could have been certified. It rarely happened that marked cases of mental disorder were admitted as voluntary boarders. The whole movement tended in the direction of facilitating the early treatment of mental disorders and would pave the way towards general hospital treatment.

Dr. RALPH NOBLE (New South Wales) emphasized the advantage which accrued from the operation of the voluntary system in the way of earlier treatment of patients, and discussed the effect of hospitalization of the mental patients. Mental hospitals ought to be run on similar lines to general hospitals. He classified nervous and mental patients into (1) those anxious to receive treatment, (2) those who were indifferent, (3) those who had no insight into their illness. Patients in the first two groups would go to hospital if they were made comfortable in congenial surroundings. Well organized psychiatric clinics would do more than any other procedure to supply treatment of mental illness in its earliest stages and could be a powerful factor in breaking down public prejudice against mental hospitals. Such clinics would also be extremely valuable in the teaching of psychiatry to medical students, and also in the training of social workers. He had found in the Sydney psychiatric clinics that the majority of the patients who presented themselves voluntarily fell into the group labelled "neurasthenia," while there were also many cases of hysteria. There was always a proportion of mental defectives and epileptics; lethargic encephalitis and syphilis accounted for many of the cases of organic lesion leading to mental disorder. Thus these clinics tended to break down the barrier which had so long existed between diseases of the mind and of the body, and gave to psychiatry and neurology their proper place in the field of preventive medicine.

Dr. ST. LEGER GRIBBEN (New Zealand) briefly considered the system from the point of view of the patient, of his friends and the general public, and of the medical practitioner. Regarding the patient, the system was eminently successful because the patient came under treatment much earlier than he otherwise would do, with correspondingly better chances of favourable recovery. The whole outlook in mental hospital administration to-day favoured an extension of the voluntary system. From the point of view of the patient's friends and the public generally, he was convinced that the voluntary system had done much to break down the old prejudices against mental hospitals, which prejudices had only too often resulted in individuals being kept at home so long that their chances of substantial improvement became remote. The system benefited the general practitioner because it furnished a basis on which he could co-operate with the mental hospital authorities in the early treatment, without formality, of those cases which would be most likely to benefit from institutional treatment.

The University Teaching of Psychiatry.

Dr. D. W. CARMALT-JONES (New Zealand) opposed proposals to teach systematic psychiatry to medical students. In his view such teaching was premature and destructive of sound professional training, if given to those who were not well grounded in organic disease. Owing to the difficult nature of psychology it was impossible to give adequate training in the subject during the existing course. No more than a smattering was possible, and a smattering of psychology was that little knowledge which was a dangerous thing; it had frequently led to serious harm being done to patients and contained the risk of an objectionable pruriency. Psychiatry was a post-graduate study for mature minds.

SECTION OF PEDIATRICS.

This Section took part in three combined meetings, and papers were read principally dealing with therapeutics. One afternoon was devoted to a visit to the Karitane-Harris Infants Hospital. Dr. A. JEFFERIS TURNER (Queensland) delivered his presidential address on infant feeding, and another address was given by Sir F. TRUBY KING.

Dr. JEFFERIS TURNER said that the prevention of disease depended on research and the practical application of the results of research. A fairly constant percentage of infants either died early, or survived only as bodily or mental defectives. Ante-natal supervision and treatment should prevent much infant wreckage. Breast-feeding was the most important preventive of infant mortality during the first year, and the infant clinic should be utilized to this end. By the medical inspection of schools and the provision of necessary treatment the State could do much. The establishment of clinics for children under school age was another valuable activity. The methods of the clinic were educative, and for their success three conditions must be observed. Nurses should be thoroughly trained; they should have the necessary medical supervision and assistance, and should co-operate with the medical profession. There should be a medical director of the whole service and medical lecturers at the training school. There should also be a local medical man attached to each clinic, whose duties should be confined to one afternoon a week. The mortality of childhood after the second year depended mainly on infections such as diphtheria, scarlet fever, measles, whooping-cough, tuberculosis, bronchitis, and pneumonia. At this age many defects were due to removable causes such as adenoids.

Dr. E. H. M. STEPHEN (New South Wales), in a paper on blood transfusion in young children, said that in the wards of the Royal Alexandra Hospital for Children at Sydney intraperitoneal transfusions of citrated blood had been given to eleven children for gastro-enteritis. Four had recovered; all were suffering from severe infections. Three marasmic infants who had survived gastro-enteritis had made a rapid recovery in a few days after intraperitoneal transfusion; in two a very toxic condition was present. Very good results had been obtained after intravenous transfusion in these children. Eight children with chorea or acute rheumatism had been favourably influenced. Children with acute rheumatism and persistent anaemia had also been transfused. Enucleation of tonsils had been performed; the patients recovered rapidly. Two choreic patients had been transfused, and an infant of 5 months with idiopathic purpura had been twice transfused and had recovered. Transfusions of the forlorn hope type in a child with a protracted meningococcal meningitis and in a pyaemic infant aged 6 months did not prolong life. A reappearance of blood cells in the urine of an anaemic convalescent nephritic was of short duration.

SECTION OF ORTHOPAEDICS.

This Section took part in three combined meetings for the discussion of cripples in war and industry, spastic paralysis, and cancer. Two sessions were devoted to papers on various subjects, which included muscle tone, the subject of a presidential address by Dr. N. D. ROYLE (New South Wales). Dr. J. RENFREW WHITE (New Zealand) read a paper on visceroptosis, and Dr. OWEN JOHNSTON (New Zealand) dealt with subacute and chronic epiphysitis. The pathology of osteo-arthritis was discussed by Dr. M. RADCLIFFE-TAYLOR (New Zealand) and Dr. K. S. MACKY (New Zealand) described the various disabilities caused by abnormality of the fifth lumbar transverse process.

SECTION OF RADIOLOGY.

The bulk of the time of this Section was devoted to combined meetings, for it took part in no fewer than six. An address on modern *x*-ray technique was delivered by Mr. E. Jerman, director of the Education Department of the Victor X-Ray Corporation, Chicago.

Dr. S. S. ARGYLE (Victoria) gave a presidential address on the progress of radiology. He said that he had been practising radiology for the last twenty-two years, and recounted some of his experiences during that time. He

drew attention to the progress that had been made, and discussed some of the problems that had been overcome. He indicated the direction in which further developments might be expected. During the war he had been particularly concerned with the equipment of an *x*-ray plant for use under service conditions for the air, and had been actively engaged in the Eastern theatre.

Dr. W. R. STOWE (New Zealand) presented three subjects for discussion. He first described two cases of Kümmel's disease (post-traumatic spondylopathy); one showed complete collapse of the first lumbar body on the left side, and in the other there was collapse of the anterior parts of the third, fourth, and fifth cervical vertebrae. In each case there was a previous history of accident corresponding with the original statement of Kümmel, and kyphosis was present. Up to 1921 only eighty-four cases of this disease had been reported. He then discussed a case of diabetes insipidus associated with defects in the skull, and said that only three cases (in children) had been recorded in the literature. The skiagram showed multiple deficiencies of a punched-out circular character in nearly all parts, more particularly in the anterior half of the skull, including the facial bones. The indication was that the skull should be examined radiographically in all cases of diabetes insipidus in children. He also described the *x*-ray treatment of Bockhart's impetigo in the adult scalp. A woman, aged 40, had had the infection for eight years. A powerful tungsten arc yielding ultra-violet rays was used; the treatment was given every other day without success. Epilation of the entire scalp was effected by irradiation, followed by the use of the ultra-violet arc and electrolysis. The hair was growing vigorously, and there were no further signs of the disease.

Dr. H. A. McCOY (South Australia) read a paper illustrated by a number of slides of 5,000 cases of gastric and duodenal ulcer, all unpublished as yet. He believed that the clinical history should be taken by the radiologist, and considered that duodenal ulcer could not be diagnosed by the history alone, but only in conjunction with a positive *x*-ray finding, though this was contrary to the teaching of Moynihan. Dr. McCoy did not agree with Moynihan's statement that a gastric ulcer was very rarely within an inch and a half from the pylorus; he had seen many gastric ulcers in which the crater was in the immediate sphincteric region. In many cases of gastric ulcer high up on the lesser curvature he had found the rhythm symptoms of duodenal ulcer, and he had seen a number of cases of duodenal diverticulum, occurring usually in the second, third, and fourth parts. He emphasized the importance of careful screening in the diagnosis of duodenal lesions, and paid particular attention to the technique of examination, which was similar to that used by Carmen Scott, Vilvandré, and Barclay.

Dr. H. F. PRAAGST (Victoria) discussed two common types of reflex dyspepsia—namely, those due to disease of the appendix and of the gall bladder. He believed that the appendix could be seen in 90 per cent. of all types of patients using the opaque meal. Of his series of 70 cases diagnosed radiologically as disease of the appendix, in 17 per cent. this organ was not seen, but all proved to be pathological at operation. Tenderness was the most valuable single sign; stasis was not by itself diagnostic. He emphasized the importance of the opaque meal investigation being employed only after the whole alimentary tract had been examined so as to obviate errors due to reflex effects on stomach and duodenum. He drew attention to the value of cholecystography by the oral method in determining whether the gall bladder was the cause of a dyspepsia, and showed films to illustrate this technique.

Dr. D. F. MYERS (New Zealand) described a method of examining the colon, utilizing the opaque enema. He gave a detailed account of the preparation and administration of a barium enema and emphasized the importance of screening in the investigation of the colon and the necessity of placing the patient in various positions in order to make a satisfactory diagnosis. He showed a number of very fine photographs reproduced in miniature from films illustrating a wide range of pathological conditions.

(To be continued.)

Reviews.

LISTER IN GLASGOW.

LISTER was born on April 5th, 1827, at Upton in Essex, of English lineage. He first became professor in Glasgow in 1860. The centenary of his birth is to be celebrated next week in London, where his work as a professor ended. It is being celebrated in Glasgow at the end of this week, April 1st, and it is therefore very appropriate that there should have been published in Glasgow two books—the one, *Reminiscences of Lister and of his Work in the Wards of the Glasgow Royal Infirmary, 1860-1869*,[1] by Sir HECTOR CAMERON; and the other, *Lister and the Lister Ward of the Royal Infirmary of Glasgow*,[2] compiled for the occasion by Mr. Ernest Maylard, honorary consulting surgeon to the Victoria Infirmary, Glasgow, Mr. James A. Morris, architect, and Mr. L. W. G. Malcolm, M.Sc., conservator of the Wellcome Historical Medical Museum in London, where a collection of relics of Lister is now on view.

In his preface to the *Reminiscences of Lister*, by Sir Hector Clare Cameron, Sir Donald MacAlister truly says that "the number of those who 'from the beginning were eye-witnesses and ministers' of his beneficent revolution in surgery becomes sadly smaller." Happy are we that so gifted and distinguished a member of the group of disciples who sat at the master's feet in the early days at Glasgow is still with us and able to make a contribution so acceptable as he does in this publication. No other living surgeon knows as much of the successive stages and steps in the evolution of the antiseptic system, from the first successful essay on a compound fracture to the full fruition of the method which banished hospital gangrene and pyaemia from those deadly ground-floor wards of the Royal Infirmary in Glasgow.

Sir Hector reminds us of the conditions of Lister's appointments in Glasgow. Like other Regius Professorships, his chair of Systematic Surgery was conferred upon him by the Crown, and he held it quite independently of the authorities of the Royal Infirmary. But if he wanted to practise what he preached and to afford clinical object-lessons to his students he must make himself so far agreeable to the directors as to induce them to appoint him to the staff of their hospital for five years. The directors were probably more anxious to help in the application of such knowledge of surgery as then existed than to increase and widen that knowledge. Sir Hector tells us a story of Lister's canvass of the directors which bears on this point. A very shrewd and influential tradesman decried the suggestion that the wards might be made use of to test the validity of theories enunciated in the lecture room as "a real Edinburgh idea." In his opinion the Infirmary should be used to cure the sick and not to educate the student. He did not realize that the surgical wards killed many more than were cured, until the "Edinburgh idea" was acted upon by the young Englishman. Although the hospital buildings were then (in 1861) new, they proved to be fearfully insanitary, to a degree remarkable even in those days of unwholesome wards. Sir Hector Cameron tells us that as a student he himself has seen as many as five men die in the same ward in one week of pyaemia following amputation for injury. Surgery in these circumstances was a cause of more grief than satisfaction to a conscientious and sensitive man such as Joseph Lister, and the effect upon him was obvious to a sympathetic observer. The successive steps in the evolution of antiseptic surgery were all watched by the eager student who is now Emeritus Professor of Clinical Surgery at Glasgow, from the crude carbolic acid, the tin-foil cap, the carbolic putty and carbolic oil, to the buried silk, and finally to the absorbable catgut ligature. The further advance to porous dressings was not made until Lister had returned to Edinburgh as professor of surgery. We are perhaps inclined to think of him as a philosophic thinker, which he

[1] *Reminiscences of Lister and of his Work in the Wards of the Glasgow Royal Infirmary, 1860-1869.* By Sir Hector Clare Cameron, C.B.E., LL.D., M.D., C.M., F.R.F.P.S. Glasgow University Publications, VI. Glasgow: Jackson, Wylie and Co. 1927. (6 × 9, pp. 45; 3 plates. 1s. net.)

[2] *Lister and the Lister Ward of the Royal Infirmary of Glasgow.* A Centenary Contribution. Glasgow: Jackson, Wylie and Co. 1927. (6¼ × 10¼, pp. xvi + 132; 27 plates. 12s. 6d. net.)

was, but not as a man of prompt action in emergency, which he also was. Sir Hector Cameron relates two incidents in which he stands out strongly as a man of deeds, in circumstances in which words were out of place, as when he rescued his own coachman from the danger of kicking horses and when he helped to save a delirious patient who had jumped out of a window.

After eight years at Glasgow, when Lister left for Edinburgh "he was able with confidence to ensure that a wound under his care pursued from first to last an aseptic course." None of those surgeons of the Glasgow Infirmary who had advised the directors that there was nothing in the antiseptic method dared give such an assurance.

Sir Hector Cameron reminds us, too, that, thanks to this immunity from suppuration, Lister was able to be a successful pioneer in bone and joint surgery and to correct the deformities due to vicious union of fracture. He left bone chips in a wound, confident that nature would deal with them satisfactorily, although, perhaps, he did not foresee that in the hands of a successor, Sir William Macewen, they would also serve a useful purpose.

In summing up his recollections and reflections Sir Hector concludes that the qualities of outstanding merit which distinguished Lister were his extraordinary powers of patience and perseverance. These, added to his great abilities and industry, carried him to the very summit of achievement accessible to the healer and the practical philanthropist.

The other book relates the efforts that were made some three years ago to save the Lister Ward from destruction and the determination of the directors of the Infirmary to persevere in its demolition. We commented on this matter at the time (BRITISH MEDICAL JOURNAL, October 27th, 1923, p. 776, and February 16th, 1924, p. 288), and after the lapse of more than three years we still wonder at the managers' decision.

Besides dealing with the controversy, in which all the valid arguments seem to be on one side, this book gives an interesting history of the three successive hospital buildings which have been used by the Royal Infirmary of Glasgow on or near the same site during the last 140 years or so.

Mr. Ernest A. Maylard, consulting surgeon to the Victoria Infirmary, Glasgow, who was formerly a manager of the Royal Infirmary, contributes a short but interesting sketch of Lister's career in Glasgow, as well as an account of the "Efforts for the preservation of the Lister Ward," and to Mr. James Morris, F.R.I.B.A., whose public-spirited efforts to secure the preservation of the ward have been beyond praise, we owe the article on the Infirmary buildings, with many interesting illustrations, as well as comments on the demolition controversy.

When the first building was erected the directors had the great advantage of using the designs of the brothers Robert and James Adam, and a handsome and dignified building was the result, to judge by the excellent illustrations which adorn this book. With the growth of Glasgow this building, even when a wing had been added, was inadequate. A new and larger hospital was erected on another part of the ground, and thus there seems to have been no excuse for the destruction of the handsome original building. Possibly those responsible for the mean-looking new building shunned comparisons with the old one, or were simply inspired by the materialistic spirit which moved the destroyers of the western towers of the adjacent cathedral. It was on the ground floor of this new building that Lister's male ward was situated, in which he applied his new method with such striking results. It was in it that he showed surgeons how to abolish hospital diseases, despite the fact that only a few feet distant was a mass of festering corpses which had been hurriedly buried there during a cholera epidemic in 1849. Separated from the other end of this ward block by only a few feet, and aligned at right angles to it, was the "Fever House," in which were treated many of the cases of fever for which Glasgow had formerly a bad name. It would have been hard to find a more severe test of the antiseptic method than was afforded by a ward thus placed.

By the beginning of the present century it became evident that a new surgical block was necessary, and it was decided to pull down the building which was opened in 1861, including the Lister Ward. Appeals for its preservation, although couched in the most respectful and persuasive terms, were all rejected, sometimes on one ground and sometimes on another; the reasons given were not all reconcilable, and none of them were convincing. Then, three years ago, as if to put the matter beyond further controversy, the ward was pulled down as far as the ground level, and in that condition the site remains to-day, unused and unsightly. Luckily the trustees of the Wellcome Historical Medical Museum acquired the materials and furniture of the ward, and the reconstruction of part of it in Wigmore Street is described by the conservator, Mr. L. W. G. Malcolm, M.Sc., in this volume.

The celebration of the Lister Centenary takes place in Glasgow on the first of this month, and we intend to publish an account of the proceedings in our next issue. Members of the medical and other learned professions, as well as many other citizens of that great city, are taking this occasion to show their pride in the fact that it was in Glasgow Lister found opportunity to prove his worth and confer on the whole world his great gift. Lister's tenure of office was by no means easy. It is significant, as Mr. Morris remarks, that so even-tempered and patient a man as he was should have felt compelled to put on record that his work at the time was "often heartbreaking, so as to make me sometimes feel it a questionable privilege to be connected with the institution." When he had succeeded in banishing hospital diseases from his ward, the directors pooh-poohed his system, attributed his success to sanitation, and resented his statement of facts. Their successors seem to have had no appreciation of the inspiration that the preservation of the ward would have been to surgeons, and of the educational value that would have attached to its maintenance in its original state.

SCIENCE AND QUAKERISM.

A COLLECTION of brilliant essays entitled *Common Sense and its Cultivation*,[3] the outcome of a life largely spent in India in an official position—Government analyst at Agra—was brought out last year by E. HANBURY HANKIN. The author is well known for his early work on immunity, of which a reminder occurs in his use of the adjective "alexic" for protective theories made up on the spur of the moment as a defence mechanism in opposition to an unwelcome proposition. Among other topics he deals with the mental ability of members of the Society of Friends, who as a result of their religious tenets were in the past driven to concentrate on business careers, education, and the study of nature. Although a small religious community such as the Quakers, numbering less than twenty thousand in Great Britain in 1900, would not appear likely to form an important recruiting ground for the Royal Society of London, he shows that this indeed is the case. In the period 1851-1900 there were on an average probably 17,000 Quakers in Great Britain, and among them there were nineteen Fellows of the Royal Society, as against 817 non-Quaker Fellows, but per million of the population this works out at the surprising figure of 1,117 for Quakers and twenty-four for others. Taking these figures at their face value Dr. Hankin argues that during the period a man had about forty-six times more chance of election to the Royal Society if he was a Quaker or of Quaker descent than if he belonged to the general population, and that, purely on the consideration of these figures and the rapid rate of increase of Quaker Fellows and the decrease of non-Quaker elections, the Royal Society should become a branch of the Society of Friends. Figures, it is said, will prove anything, and Dr. Hankin, after putting forward this fantasy, fully admits that the small numbers dealt with do not justify such a conclusion. Among the Quaker members of the medical profession, to which their social and intellectual atmosphere specially fitted them, Thomas Young was the most outstanding example of an all-round

[3] *Common Sense and its Cultivation.* By Hanbury Hankin, M.A., Sc.D. With a foreword by C. S. Myers, M.D., Sc.D., F.R.S. London: Kegan Paul, Trench, Trubner and Co., Ltd.; New York: E. P. Dutton and Co. 1926. (Cr. 8vo, pp. viii + 289. 7s. 6d. net.)

genius and the most distinguished man of science who ever became a physician; Lord Lister's is the most immortal name in the practice of surgery, and it is a hundred years ago since he was born to make surgery safe. Others such as Thomas (Baron) Dimsdale, John Fothergill and Lettsom, Thomas Hodgkin, philanthropist and pathologist, and Jonathan Hutchinson have left their impress on the history of medicine.

Miss ISABEL GRUBB has collected a large amount of material for her *Quakers in Ireland, 1654-1900*,[4] which carries on the story told in Dr. Rutty's *History of the Rise and Progress of the People called Quakers in Ireland*, published in 1751, since which date no such connected account appears to have been put before the public. Most of the early Quakers in Ireland went over from England as settlers between 1650 and 1680, and though at first persecuted did much to advance educational and economic progress. A Cork Quaker, William Martin, in 1838 recognized the great possibilities latent in a young Roman Catholic priest, and so at his suggestion Father Theobald Mathew undertook his famous temperance crusade throughout Ireland.

LIGHT TREATMENT.

IN 1907 Dr. L. JAUBERT established at Hyères on the Riviera a heliotherapeutic clinic, which he claims to have been the first in France. Since then he has been actively engaged in studying the effects of natural heliotherapy on the prevention and treatment of disease. He has now summarized his experience in a book.[5]

It seems to us of great importance at this time, when treatment by light rays of various kinds has acquired a sudden and to some extent unjustifiable popularity, that those who have had most experience in this field of work should put forward their views so as to guide and restrain the younger and more enthusiastic advocates of the method.

It is so easy to forget that ultra-violet light is a powerful protoplasmic poison, and like other protoplasmic poisons, such as mercury and arsenic, must be employed with the greatest caution. All the more is this necessary when it is remembered that, unlike the chemical poisons, the dosage of ultra-violet light cannot be measured with accuracy. And even though care is taken to avoid actual burns or other gross effects, we have far too little knowledge at present to state that its action is uniformly beneficial. The Northern races have attained an equilibrium in which the actinic rays of the sun play only a small part, and it is on *a priori* grounds very doubtful whether their resisting power to infection is likely to be materially increased by the almost unlimited exposure that is now being advocated both in medical and lay journals. This is not said to discourage or to depreciate in any way the value of light treatment; it is only to draw attention to our ignorance of the action of light rays on the biological processes of the organism.

One point made by Dr. Jaubert is of profound importance. It is that natural heliotherapy and treatment by artificially generated ultra-violet rays are radically different. To call the latter method "artificial heliotherapy" is a misnomer. The most valuable factor in natural heliotherapy is the free exposure to open air; the direct effect of insolation on the tissues is, he considers, insignificant. On the other hand, phototherapy, dispensing with the action of fresh air currents, relies exclusively on the direct action of the light rays. Though admitting the value of the latter method of treatment in certain conditions, the author has no doubt that it is very much more restricted in its application than is natural heliotherapy.

We would recommend this book to all who are interested —and who is not?—in the sun cure, trusting that it will, by demonstrating how empirical is our present knowledge of light treatment, stimulate many to a more profound and scientific examination of the part played by the actinic rays in the physiology and evolution of living protoplasm.

A second edition of the English version of Dr. ROLLIER'S *Heliotherapy*[6] has now appeared. His work at Leysin and his book giving an account of his work, published for the first time in English in 1923, are so well known that a brief notice and a warm welcome to this second edition are sufficient. A full account of the method of graded exposure to the sun's rays is given, together with details of the special apparatus used in the different deformities. A feature of the new, as of the former, edition is the large number of excellent illustrations demonstrating, not only the cure of the local lesion, but also the remarkable "transfiguration" of the whole body effected by the treatment. Radiographs of bone lesions before and after treatment are also numerous and equally striking. The clinical conditions dealt with are mainly tuberculous disease of bones, joints, and glands; non-tuberculous conditions are dealt with in a separate chapter. There are also short sections on climate, altitude, and the general action of sun rays on the body.

The first edition of a book entitled *Ultra-violet Radiation and Actinotherapy*,[7] by Drs. ELEANOR and W. KERR RUSSELL, was reviewed on April 17th, 1926 (p. 704). We have now received the second edition, which is nearly twice the size of the first, and contains additional information, after a further year of experience, on the value of the various types of lamps now in use. The writers describe themselves as "two medical practitioners," but they may justly claim a special competence in this sphere of practice, and in the ability to make plain a procedure that is more easily seen than appreciated from the printed word.

They have generally found the various types of lamps satisfactory, particularly the air-cooled mercury vapour lamp; the difficulty of the lamp is, not any inability to get sufficient radiation, but in gauging the correct amount required by the patient. The tungsten arc gives off more radiation and is cheaper to install, but upkeep, owing to the high price of tungsten electrodes, is great; also it produces unpleasant fumes, and needs constant hand regulation. The carbon arc is very suitable for hospitals where many patients are treated together. Briefly, the faults of the three are: The mercury vapour lamp, fragile and has a comparatively short life; the tungsten arc, fumes, and the running costs are high; the carbon arc, costly in current. In the new edition there is an interesting chapter on the history of light therapy, and an extended record of types of cases that are benefited by the treatment.

The book may be commended to the attention of practitioners who contemplate making use of this mode of treatment, and they will find in it a clear account of the scientific basis of the treatment and the details of its application.

The appearance of *The Artificial Light Treatment of Children*,[8] by Dr. KATHERINE M. L. GAMGEE, affords evidence of the great popularity of this method of treatment at the present time. Dr. Gamgee relates her experience and results at the Hull Corporation Artificial Light Clinic, especially in conditions of rickets, anaemia, and malnutrition in young children. An account is given of the administrative details of such a clinic and of the various kinds of suitable light apparatus; of the technique of exposure, and of the record of clinical data, along with illustrative notes from a number of case records. The author is convinced of the great value of this treatment, although it is a little difficult for a critical reader to accept all her conclusions from the data given. It would seem almost too good to be true that the use of violet rays in such clinics would do anything more than palliate the evils produced

[7] *Ultra-violet Radiation and Actinotherapy*. By Eleanor H. Russell, M.D., B.S., and W. Kerr Russell, M.D., B.S. With forewords by Sir Oliver Lodge, F.R.S., D.Sc., LL.D., and Sydney Walton, C.B.E., M.A., B.Litt. Second edition. Edinburgh: E. and S. Livingston. 1927. (Demy 8vo, pp. xxxi + 429; 168 figures. 15s. net.)

[8] *The Artificial Light Treatment of Children*. By Katherine M. L. Gamgee, M.R.C.S., L.R.C.P., D.P.H. With an introduction by Professor Leonard Hill, M.B., F.R.S. London: H. K. Lewis and Co., Ltd. 1927. (Demy 8vo, pp. xx + 172; 33 figures, 16 plates. 10s. 6d. net.)

by lack of sunlight and fresh air in the homes of our poor city populations. Natural sunshine together with fresh air is the ideal to be aimed at; and it would be regrettable if excessive enthusiasm about the value of this artificial substitute were to slacken our efforts in working for the radical remedy—which consists in good houses and the introduction of fresh air into the homes and lives of city dwellers.

Dr. E. MAYER'S *Clinical Application of Sunlight and Artificial Radiation*[9] is the kind of book on this subject which is to be welcomed, for the author has had considerable personal experience in the use of ultra-violet radiation in various clinical conditions of tuberculosis. With this foundation and with a long experience of all modern methods of treatment in tuberculosis acquired at Saranac Lake, New York, he has attempted a comprehensive survey, not only of the clinical applications of light treatment, both natural and artificial, in tuberculous conditions, but of the more fundamental and much more important problem of the biological action of light upon human tissues. Such a survey can only be given in a provisional way, but even now its need is being widely felt as a critical check on the extravagant claims that are being made, especially for artificial light therapy. The first part of the book is the more important; it deals with the nature of various forms of radiant energy and with their effects upon animals, plants, and bacteria, and is written with an extensive knowledge of the growing literature on this subject. The sections on the clinical applications of light treatment include, not only his own personal experience in tuberculosis, but also sufficient reference to the results of other workers in Europe and America. The whole book is a well balanced critical account of a large subject, the importance of which is being more and more realized, and for which accurate and scientific data are urgently required.

The book is well illustrated, and is also provided with an enormous bibliography. The latter fills nearly sixty pages, and as not even the majority of these references are quoted in the text it is of little value except that it indicates the enormous output of writing on the subject, much of it, we fear, of very doubtful value. But Dr. Mayer's book will certainly take a much more honourable place in the literature of the subject.

NOTES ON BOOKS.

DUVERGER of Strasbourg and VELTER of Paris have collaborated in writing a textbook of ophthalmic surgery (*Thérapeutique chirurgicale ophthalmologique*[10]) which, within our knowledge, is the best of its kind in French. The whole field is covered. A large amount of space is devoted to the question of anaesthesia; the authors strongly advocate regional applications. They give in minute detail the technique they practise, and express the view that with few exceptions it should supersede the employment of general anaesthetics. A special feature is made of plastic operations on the lids and conjunctiva, to which about a quarter of the book is assigned. The operation advised in those cases of lacrymal disease where nasal drainage is feasible is a modification of the technique of Dupuy-Dutemps and Bourguet. In the surgery of the cornea stress is laid upon the advantage of a conjunctival flap in chronic marginal ulcer, and superficial corneal grafts are suggested as worthy of a trial in some cases of central opacity. Cysts and tumours of the iris which are amenable to local removal are freely excised *in situ* with the surrounding iris tissue after a hemisection of the cornea has been made and the whole half of the cornea has been folded back *en bloc*, exposing the neoplasm "*à plat et au grand jour.*" For such a procedure retrobulbar anaesthesia is necessary. The old-fashioned ways of performing cataract extraction are advocated, and the various methods of intracapsular extraction are dismissed as not compensating for the increase of risk by any theoretical or cosmetic advantages. For acute glaucoma iridectomy, and for chronic glaucoma the technique of Lagrange, are given first consideration. In enucleation regional anaesthesia only is advised. The book is well written, and its most striking feature is its wealth of clearly drawn illustrations; they are much above the average, and, like the illustrations of all surgical textbooks, show how beautiful and easy surgical manipulations really are.

[9] *Clinical Application of Sunlight and Artificial Radiation.* By Edgar Mayer, M.D. London: Baillière, Tindall and Cox. 1926. (Med. 8vo, pp. xvi + 458; 16 figures, 37 plates. 45s. net.)

[10] *Thérapeutique chirurgicale ophthalmologique.* Par Prof. Duverger et Prof. Velter. Paris: Masson et Cie. 1926. (Roy. 8vo, p. 630; 45 figures, 40 plates. 18s. 4d.)

Dr. FRANKLIN H. MARTIN, Director-General of the American College of Surgeons, visited South America in 1920 and 1921, and published an account of his tours in a book entitled *South America from a Surgeon's Point of View*, which we reviewed on March 4th, 1922 (p. 355). Since then other Fellows of this College have paid similar visits, and Dr. Martin has, therefore, revised his original book extensively to include an account of the *Vandyck* cruise arranged by the College in 1922-23, and journeys of Drs. Francis P. Corrigan, W. J. Mayo, A. J. Ochsner, and E. I. Salisbury, with a view to indicating the position to-day of medical practice in the Latin-American countries. The present volume, entitled *South America*,[11] contains an interesting description of each of its constituent countries illustrated by many photographs, and an account of their medical institutions, including their relation to the American College of Surgeons. It is stated that up to the present time the Fellowship of the American College has been conferred upon 265 Latin-American surgeons, in addition to several honorary Fellowships awarded to certain of the more distinguished among them. Dr. Martin has compiled a considerable amount of information which will interest and assist travellers, historians, or medical practitioners who propose to visit South America. An English-Spanish and an English-Portuguese vocabulary increases the value of the book.

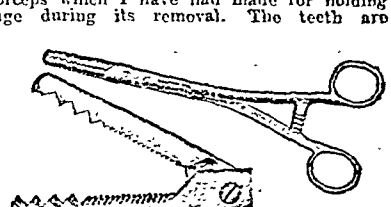
Dr. F. F. IMIANITOFF, assistant to the gynaecological research department of the Institute of Anatomy in Brussels, has prepared an English translation of Dr. SERGE VORONOFF'S book on the treatment of old age by grafting, which we reviewed on October 23rd, 1926 (p. 736). This translation[12] is illustrated by photographs, and is printed clearly. The book contains an account of the operative technique in man and monkeys, and a report of the results obtained.

The *Pocket Dictionary for Midwives and Maternity Nurses*,[13] edited by DORA VINE, contains a list of obstetrical and gynaecological terms, with phonetic pronunciations, and a short account of various medicaments used in midwifery. It is, as the title claims, very portable, and should be found useful by midwives, maternity nurses, and students for the C.M.B. examination.

In a small manual entitled *Leadership*[14] Dr. WILLIAM COLBY RUCKER suggests rules of conduct for the younger officers of the United States Public Health Service. He describes in general terms the elements of character and personal behaviour which are essential for professional success, and gives numerous hints as to the way in which the medical officer should deal with his colleagues and the public.

[11] *South America.* By Franklin H. Martin, C.M.G., D.S.M., M.D., LL.D., F.A.C.S. Introduction by William J. Mayo, M.D., D.Sc., LL.D., F.R.C.S.Eng., Edin., Ire., D.S.M. Revised edition. New York, Chicago, London, and Edinburgh: Fleming H. Revell Company. 1927. (4½ × 7¼, pp. xxiv + 411; illustrated. 3 dollars.)

[12] *The Study of Old Age and My Method of Rejuvenation.* By Dr. Serge Voronoff. Translated by Fred. F. Imianitoff, D.S.C., B.A., M.R.C.S. London: The Gill Publishing Company, Ltd. 1926. (5¾ × 8¼, pp. 155; 36 figures.)



[13] *Pocket Dictionary for Midwives and Maternity Nurses.* Edited by Dora Vine. Nursecraft Series. London: H. Edgar Smithers. 1927. (Fcap. 16mo. 1s. 6d. net.)

PREPARATIONS AND APPLIANCES.

Forceps for Operations on the Semilunar Cartilage.

MR. F. WILSON STUART, M.D., Ch.M. (*Birmingham*), writes: The illustrations show a forceps which I have had made for holding the semilunar cartilage during its removal. The teeth are so fashioned that they crush and grip the cartilage tightly instead of cutting through and breaking it up—an action which allows of continual slipping. The instrument is designedly made long to allow of the hand holding it being well away from the wound.

It has been thoroughly tested, and proved entirely satisfactory. The makers are Messrs. Philip Harris and Co., Ltd., Birmingham.

British Medical Journal.

SATURDAY, APRIL 2ND, 1927.

CERTIFICATION OF THE INSANE AND THE HUME-SPRY CASE.

THE certification as insane of a mentally disordered person has always rightly been regarded as an exceedingly grave matter, and, by the medical men directly concerned, as a painful duty. Deprivation of personal liberty, loss of civil capacity, and real handicap to re-employment after recovery, to mention some only of the disabilities certification entails, carry so much weight that relatives and doctor alike often go very far to avoid this step. But these considerations, however greatly they may delay certification, and (too often) treatment at expert hands during an early and most favourable period, do not expose the real difficulty or dilemma in which the medical practitioner may easily find himself.

As pointed out on behalf of the British Medical Association to the Royal Commission on Lunacy[1] by several high authorities, if the medical practitioner fails to certify a case with suicidal or homicidal tendencies and a tragedy ensues, he may be held responsible; or, if he takes charge of the case *without* certification, Section 315 of the Lunacy Act may be invoked and he be found guilty of a misdemeanour; while if he certifies the case he exposes himself to an action by the patient on recovery. The case Harnett *v.* Bond, heard a year or two ago, has done nothing to allay professional disquietude in this matter, but instead has so considerably increased the reluctance of medical men to handle so many-pointed an instrument as a lunacy certificate that in some districts, it has been said, medical men refuse to certify in any circumstances. In consequence, in these districts there is an increase of the practice of sending patients, not paupers, to Poor Law institutions for certification and transfer to mental hospitals, instead of, as is so much to be desired, to the mental hospitals direct. This is only one example out of several, but in general it may be said that this case has accentuated the need for that " accommodation of legal standards and medical considerations " which the Royal Commission described as the crux of the problem before it.

In such circumstances the result of the Hume-Spry case was awaited by all with anxious interest, and the congratulations which happily we were able to offer to Dr. Percy Smith and Dr. Watson last week must have been echoed by the medical profession as a whole, and also by that considerable body of laymen concerned with and about the care and treatment of the mentally afflicted. So much, however, has public attention been focused on the fifteen days' hearing concluded on March 22nd that the fact may have been overlooked that as far back as January, 1926, the defendants made application to a Master of the King's Bench Division, pursuant to the Lunacy Act, 1890, Section 330, Subsection (2), to stay the proceedings, and that the order of the Master staying the proceedings was affirmed by the Judge in Chambers. Mr. Hume-Spry then appealed to the Court of Appeal, which held, in the light of the affidavits of the plaintiff's expert medical witnesses, that a prima facie case that the defendants had acted without reasonable care had been shown, and consequently the action must proceed and the orders of the Master and the Judge be set aside. An explanation of the ruling of the Court of Appeal will be found in our issue of March 13th, 1926 (p. 508). Put shortly, the Court of Appeal held that the question for decision by the Master under Subsection (2) was not, Did the defendant medical men act in good faith and with reasonable care? but, Has the plaintiff disclosed a prima facie case of negligence? It appears, therefore, that although this subsection may powerfully protect medical men against frivolous litigation, cases in which the plaintiff is able to bring sufficient evidence in support of his claim to disclose a prima facie case of negligence, even when there appears to be a good defence, must go forward to trial under Subsection (1). Where, as in this case, the evidence includes sworn statements by medical men of professional eminence supporting the plaintiff's contention of lack of good faith or reasonable care, it would seem that a prima facie case can hardly be denied.

It may be recalled that the Royal Commission recommended certain amendments of both subsections of Section 330 which would place the onus of proof of bad faith and lack of reasonable care upon the plaintiff, and also would permit the action to be stayed unless the judge and court were satisfied that there was substantial ground for alleging bad faith or want of reasonable care. These recommendations, though they fell far short of the proposals of the British Medical Association, would, if adopted, certainly increase the measure of protection afforded at present. Whether the alterations of Subsection (2) recommended by the Royal Commission would have allowed the action to be stayed at its interlocutory stage may be questionable; but having regard to the serious statements made against several who had the misfortune to be involved, it is now clear that it was far better that this action should have been tried by a jury, and that the same verdict which fully cleared both defendants of the charges of bad faith and negligence brought against them completely vindicated the honour of those aspersed.

It will have been observed by those who have followed the case that at every stage of the action great stress was laid by some of Mr. Hume-Spry's expert witnesses on the necessity of making a full physical examination, without which, they said, the defendants should not have arrived at their conclusion. This contention is untenable. We should be the last to minimize the importance of making the fullest possible physical examination, but—and this cannot be said with too great emphasis—the only criteria for the purposes of certification as insane are psychological, and concern the mind and conduct of the person examined. Moreover, evidence for the defence showed that Mr. Hume-Spry had been under treatment in Ministry of Pensions hospitals for some years, where he had been carefully examined physically; and that not only had both defendants been informed of this fact, and that he showed no signs of any organic disease, but that the actual medical case-sheets were produced to Dr. Percy Smith at the time of his examination of the plaintiff.

Had the case gone otherwise it might have been necessary to examine at some length the suggestion that the defendants acted in bad faith because they did *not* make inquiries of independent persons in a search for evidence corroborative of the plaintiff's delusions. Fortunately it is still not required of the

[1] Report of the Royal Commission on Lunacy and Mental Disorder. Printed and published by H.M. Stationery Office. 1926. Price 3s. 6d.

certifying medical man that—to quote the apt phrase of defending counsel—he constitute himself into a kind of amateur divorce court.

The principal charge made by the plaintiff against the Ministry of Pensions was that a plot or conspiracy existed to separate him from his wife by detaining him in hospitals, and that his eventual certification was the culmination of such conspiracy, and was engineered by headquarters officials of the Ministry of Pensions in conjunction with the plaintiff's wife to cover her alleged misconduct with the medical superintendent of a Ministry hospital in 1920. The evidence showed that these allegations were baseless, and the product of a mind dominated by an inordinate degree of morbid suspicion and jealousy. There was, on the other hand, ample proof that the Ministry of Pensions, in accord with its publicly avowed policy, kept the plaintiff under observation and treatment in its hospitals for some years in the hope of avoiding certification, and that it was only when he was considered to have become potentially dangerous and showed marked deficiency of self-control that legalized detention became essential.

At the judge's direction the documents connected with the case were retained in the custody of the court in order that the Director of Public Prosecutions might consider whether or not he should take criminal proceedings against Mr. Hume-Spry for perjury or such other offence as he might think should be disclosed. If it be true, as was stated during the hearing, that this action was subsidized by a society—the Ex-Services Welfare Society—whose claims, supported by distinguished patronage, are constantly before the charitable public from whom it derives its funds, we can only deplore the fact.

It is always a comforting reflection that out of evil good may come, and if, following the great publicity given to the case and the complete vindication of the defendants, there ensues a greater degree of confidence in the good faith of medical action, and a less suspicious attitude of the public towards its servants acting in the discharge of their often difficult duties, this trial, however considerable the pain to the defendants, may yet prove a blessing in disguise.

PARALYSIS OF THE VOCAL CORD AND OF THE DIAPHRAGM.

APART from their value as experiments in nerve anastomosis, the investigations reported by Sir Charles Ballance and Mr. Lionel Colledge in the current and preceding numbers of the JOURNAL are of physiological interest in that they deal with one aspect of what has been termed "central nervous response to peripheral nervous distortion."[1] The object of their experiments has been to see if a paralysed vocal cord can be so innervated by a motor nerve which normally innervates muscles other than those of the cord that the latter regains its normal co-ordinated activity, moving rhythmically in respiration and playing its part in phonation. Their observations have been carried out on dogs and monkeys, and the essential results were described concisely by Mr. Colledge in this JOURNAL two years ago (March 21st, 1925, p. 547). Certain additional facts concerning the restoration of function in the diaphragm after section, partial or complete, of the phrenic nerve and the anastomosis of its distal end with the descendens hypoglossi are embodied in the present papers, together with a wealth of experimental detail. Also there is the brief account of a human case in which they have applied the method of nerve anastomosis that their animal experiments have shown to be most efficacious. Briefly, the facts of observation are these: Anastomosis of the distal end of the cut recurrent laryngeal nerve with either the vagus trunk or with the descendens hypoglossi restores a tension of apparently normal degree to the paralysed cord, but fails to produce the normal respiratory movement of the cord. Under partial asphyxia the cord does show some adduction and abduction movement, indicating that motor nerve fibres have traversed the suture and gained the musculature—a conclusion confirmed by stimulation experiments—but a useful normally co-ordinated movement of the cord is not restored. Following anastomosis of the distal end of the cut recurrent laryngeal nerve with the proximal end of the cut phrenic nerve, or an end-to-side anastomosis of the former nerve with the partially divided phrenic, there appear after the lapse of some months movements on respiration of normal amplitude and form in the previously paralysed cord. However, these tend with the further passage of time to increase in amplitude so as to exceed those of the normal cord of the opposite side. Further, when a similar nerve division and anastomosis is performed on the opposite side in the same animal, paradoxical movements tend to develop in the newly innervated vocal cords. So that the normal abduction of inspiration and the adduction of expiration are reversed, and stridor develops. In the case of the unilateral operation a similar disorder of movement is apt to appear under anaesthesia.

It would seem from the observations thus summarily stated that while a restoration of muscular contraction in the intrinsic muscles of the larynx can be secured with reasonable certainty by phrenic-recurrent laryngeal anastomosis, the restoration of co-ordinated movement in the cords is a result much more difficult of attainment. As the authors point out, a similarly deficient functional result is apt to follow attempts to re-innervate the paralysed facial muscles by nerve anastomosis, and it is possible that, as with the face so with the vocal cords, re-education exercises may overcome this defect up to a certain point. It is probable, however, that the various movement complexes, voluntary and reflex, in which the vocal cords normally take part are even more highly differentiated than those in which the facial muscles engage, and that in consequence a perfect physiological result from recurrent laryngeal anastomosis will be even more difficult to obtain. After describing the movements of the glottis in simple respiration, Gowers remarks in his textbook: "If the action be thus complex in simple opening and closing the glottis, how much more complex must it be in the delicate and varied actions by which is produced the infinite variety of vocal sounds." And we have also to consider the harmonious co-operation in which the glottis normally works with the other muscles of respiration.

In the endeavour to find an explanation for certain of their observations, the authors wander more deeply into the realms of speculation than the physiologist will be prepared to follow, while they record observations—not, indeed, essential to their main purpose, but made in the course of a prolonged investigation—which he will not be able to accept. Thus it is stated that anastomosis of the distal end of the cut facial nerve with the proximal end of the cut lingual will secure effective re-innervation of the facial muscles, and that a similar sensory-motor anastomosis of the distal end of the phrenic with a cervical cutaneous

[1] Osborne and Kilvington, *Brain*, 33, 1911.

nerve will restore movement to the paralysed half of the diaphragm. These appear to have been isolated observations which, in view of their unusual character, it might have been wiser not to embody in their paper. Further, there is the statement that stimulation of the hypoglossal nerve evokes reciprocal innervation of the hyoid muscles, contraction of the supra- and relaxation of the infra-hyoid. It is clear that the acceptance of this as an accurate observation would involve a revolution in the body of accepted neuro-physiology.

These aspects of their paper do not, however, invalidate its main thesis, and in the discovery of an operation which may with reasonable certainty relieve the subject of a double abductor paralysis from the danger to life in which he stands, the authors have every ground for satisfaction. It seems that in unilateral phrenic (end-to-side)-recurrent laryngeal anastomosis they have devised such an operation. The reader who wishes to ascertain the essential facts of observation upon this, the authors' main purpose in their investigation, may with advantage refer to the earlier paper published by one of them in this JOURNAL and cited above.

THE NEW MIDDLESEX HOSPITAL.

WHEN the authorities decided that the Middlesex Hospital would have to be rebuilt, the appeal to the public for support in this important undertaking mentioned the sum of half a million pounds. This amount, however, represented only the estimated cost of replacing the existing, condemned portion of the hospital, and, as distinct from the "rebuilding scheme," the "development scheme," announced at a meeting of subscribers in November last, including the provision of a new out-patient department, the erection of paying wards, adequate accommodation for the nurses, and certain developments in connexion with the medical school, is dependent entirely upon the special generosity of friends of the hospital. The Ferens Institute of Otology was opened the other day (as recorded in our issue of February 12th, p. 296), and building work in connexion with the Courtauld Institute of Biochemistry is proceeding. Subscriptions towards the sum necessary for the erection of paying wards have already reached the total of £10,000, and more is promised. At the annual court of governors, held on March 24th, Prince Arthur of Connaught was able to announce that yet another important item in the development scheme could now be proceeded with, since an anonymous donor had made the splendid gift of £160,000 for the provision of a complete and up-to-date hostel and training school for nurses. At present the nurses at Middlesex Hospital live in five separate buildings, but thanks to this most generous gift it will be possible to erect a building on a site adjoining the hospital in which the whole nursing staff could be housed under conditions where the necessary comfort and facilities for instruction, recreation, and social intercourse could be realized. This donation has relieved the governors of the hospital of much of their anxiety with regard to the development scheme, for the space in the new main hospital buildings can now be planned to contain all the necessary accommodation and equipment for treatment in one building. The modest donor, whose anonymity is most strictly preserved, was inspired to make his magnificent contribution by the good offices of Mr. A. E. Webb-Johnson, surgeon to the hospital. The nurses of this hospital have again to be congratulated on their good fortune, for it was only a short time ago that Dr. Essex Wynter made the generous offer of his country house and certain cottages, together with sufficient endowment, to provide a home for retired members of the nursing staff.

HARVEY MEMORIAL: REBUILDING HEMPSTEAD CHURCH TOWER.

WILLIAM HARVEY died at the age of 80 on June 3rd, 1657, and his remains were deposited in a vault adjoining the parish church of Hempstead in Essex, seven miles from Saffron Walden and some fifty from London. By the middle of the last century this family vault underneath the Harvey Chapel had become ruinous, and early in 1882 the church tower fell, and is still a heap of stones in the churchyard. On St. Luke's Day, 1883, the body was removed from its resting place and laid in a white marble sarcophagus erected by the Royal College of Physicians of London in the chapel above the vault. As recorded two years ago,[1] a project was set on foot to restore the fallen church tower as a further memorial to William Harvey at an estimated cost of £5,000. This appeal had the warm support of the Royal College of Physicians, and a committee was appointed, including the bishops of the three neighbouring dioceses, the President of the Royal Society, and the President and other distinguished Fellows of the Royal College of Physicians, with Lord Stanmore, treasurer of St. Bartholomew's Hospital, as its chairman. A meeting of the committee of the Hempstead Church Tower Restoration Fund was held recently at the Royal College of Physicians, when the following report was received:

	£	s.	d.		£	s.	d.
Donations received ...	431	10	6	Expenses of appeal...	59	4	10
				Purchase of £360 5% War Stock ...	363	6	9
Interest on investments, etc.	32	2	8	Balance in hand and at bank	41	1	7
	£463	13	2		£463	13	2

There is, in addition, £515 5s. 7d. collected locally previous to this appeal and invested in 5 per cent. War Stock. It was resolved to keep the fund open in the hope of receiving sufficient further support to commence the rebuilding of the tower. Donations from members of the medical profession may be sent to Dr. Sidney Phillips, joint honorary secretary of the Fund, the Royal College of Physicians, Pall Mall East, S.W.1.

THE BEIT MEMORIAL FELLOWSHIPS.

THE administrators of the Beit Memorial Fellowships for Medical Research have resolved to increase their annual value. The change will take effect on October 1st, and will then apply to all fellowships—those now held and such as may be awarded next July. The annual value of a junior fellowship will then be raised from £350 to £400 a year, a fourth-year fellowship from £400 to £500, and a senior fellowship from £600 to £700. This step has been taken by the trustees after consultation with the Advisory Board of the Beit Fellowships and others competent to express an opinion. The necessary expenses of an undergraduate at Oxford or Cambridge cannot be directly compared with those of a Beit Fellow, for the terms cover barely half the year, whereas the science worker must have provision for nearly twelve months. The need for an increase is felt in particular with regard to the junior Fellows, who are practically dependent on the salary. If the Fellow's circumstances are too straitened he or she is discouraged from attempting, during what are very formative years of life, to correct the somewhat intense specialization the work of the fellowship entails by recourse to some broad cultural interest or pleasure. No one can doubt that this risk exists, for even physiology and pathology are breaking up into specialties, so that a neurological physiologist may know very little about biochemistry, and both will tend to limit their general interests in the cultural life about them. Incidentally we may recall that the Rhodes scholarships have recently been increased to £400 a year, and even

[1] See BRITISH MEDICAL JOURNAL, May 9th, 1925, p. 895.

junior Beit Fellowships are held by persons distinctly senior to the Rhodes scholars. An election of junior Beit Fellows will take place in July next, as more fully stated in a notice which will be found in our advertisement columns. The usual tenure of a junior fellowship is for three years, and those elected next July will be required to begin work on October 1st. Forms of application and all other information can be obtained from the honorary secretary, Sir James K. Fowler, at 35, Clarges Street, London, W.1. Applications must be received by him on or before June 1st.

CRÉSOPIRINE.

THE great importance of the coal tar antipyretics and analgesics, and the clinical success of drugs of such comparatively recent origin as acetyl salicylic acid and cinchophen (atophan), make new derivatives of this group of particular interest. Two theses for doctorates at Lille have just reached us dealing with a new derivative—namely, acetyl-ortho-cresotinic acid (1-2-5) ($CH_3.C_6H_3.COOH.OCOCH_3$), which was prepared in 1926 by Professors Carrière and Gérard and named by them crésopirine. The cresotinic acids were investigated by Stockman in 1912 and found to be antipyretic, and acetyl p-cresotinic acid (ervasin) was introduced at that date for the same purpose. In the thesis of Dr. Madeleine Notredame the mode of preparation of the substance is described and a certain number of experiments and clinical observations are reported. M. Serre in his thesis (1927) gives an account of a considerable series of clinical observations made with this drug. Both authors show that crésopirine has an antipyretic and analgesic effect on acute rheumatic fever equal or superior to that of sodium salicylate. Further, they claim that in chronic rheumatism crésopirine has an analgesic action superior to that of aspirin, and often produces benefit when the latter drug fails. They claim also that the toxicity of crésopirine is very low. The group of coal tar derivatives which possess antipyretic and analgesic action is large, and it is particularly difficult to estimate accurately the relative value of these drugs. The theses under discussion suggest, however, that crésopirine is well worth a trial, particularly in refractory cases of chronic rheumatism.

MILK IN HOLLAND AND DENMARK.

LAST year the Health Committee and the Port Sanitary and Hospitals Committee of the City of Liverpool instructed their chairmen, the medical officer of health, and the chief veterinary officer to visit Holland and Denmark for the purpose of studying Continental methods in the production and distribution of milk. The deputation was accompanied by twenty-four other persons, representative of the Liverpool Cowkeepers' Association, of farmers, and of distributing firms. The visit lasted from September 27th to October 3rd. In its report the deputation states that the standard of knowledge and interest in milk amongst producers, distributors, and the general public in the countries visited is high; that more milk per head is consumed than in this country; that the price is regulated according to quality; and that the feeding and management of cattle are more scientifically conducted. The handling and distribution of milk are conducted from large centres, where the hygienic arrangements are all that can be desired. It is admitted that the farms visited were specially selected, and that there are farms in England where the standard of efficiency is as high as in Holland and Denmark. But it is said that the average farmer in this country does not understand the scientific feeding of cows, and that the supervision of small milk dealers is very difficult. The construction of cowsheds in Holland and Denmark is very simple, cleanly, and satisfactory. In one farm in Denmark the cows are fed principally on concentrated food and sugar beet, and are rationed according to the milk yield. In a farm in Holland automatic drinking vessels are supplied, and it has been found that each cow in milk requires about four gallons of water for every gallon of milk produced. When at grass the animals in Denmark are tethered each day, so that they have to eat within their bounds, and the grass of the field is economically consumed. Great care is taken in milking to prevent pollution by excreta, and in some places the tails of the cows are tied by the tip to a wire running the length of the cowshed, so that when the animal lies down the tail, while it can still be used, is raised from the excreta. In several places in Holland electrically driven machines are used for milking. The cows are often groomed night and morning, and the hair on the quarters, udders, and tails clipped. The distributing firms are large, and have well trained staffs and well appointed machinery. The distributing dairy of the Danish Milk Company can deal with 40,000 gallons of milk a day and one ton of butter. In Denmark there are five grades of milk, while in Great Britain, according to the deputation's report, there are only two types—graded milk and "milk." At the Amsterdam University Professor van Leersum told the deputation that exposure of milk to air renders it less nutritious, in that at the end of sixteen hours vitamin C and vitamin A are practically non-existent. The members of the deputation are of opinion that in Great Britain clean milk production is difficult owing to faulty construction of cowsheds, lack of knowledge of modern methods in producers, and absence of distinctive prices for various standards of milk. Their slogan is "propaganda," through the press, by wireless methods, and by clean milk competitions.

OCCUPATION ANALYSIS.

THE National Institute of Industrial Psychology has issued recently a report[1] on occupation analysis, the outcome of team work by the staff of the vocational section of the institute. The introduction of the report is concerned with the definition of terms; and this is very necessary in a comparatively new psychological pursuit. We learn that "occupation analysis" includes every kind of inquiry that the vocational adviser's study of employment entails, and means the analysis of occupations in order to discover the human capacities which are essential to success. It is of use, we are told, in vocational guidance, vocational training, vocational selection, and in industrial psychology. Evidently the method aims at placing on a scientific basis the rough-and-ready methods of trial and experiment hitherto adopted by employers and their workpeople. General and special information about every occupation and each of its processes is collected, and the information recorded under various headings, including a general description of the process, the psychological and physical requirements in the worker, the method of entry into the occupation, and the prospects it offers. The systematic observation of occupation should, it is urged, be carried on by the help of psychological methods; consequently the information under the heading "psychological" is especially complete, and contains a record of the intelligence required, the special abilities that are useful, the degree of manual skill involved—for the estimation of which a system of symbols has been devised—the temperament most suited to the work, and the general or special experience which the worker should possess. The method of recording the information gathered is illustrated by a detailed account of the occupation of laundry work, from the receiving department, through the various processes of washing and

[1] London: Published at the offices of the Institute, 329, High Holborn, W.C.1. 2s.

ironing, to the final stage of packing and dispatching. The reader will learn that in the sorting department a temperament is needed which has "no marked dislike of handling soiled linen." The calenderer must be calm and equable, and able to resist monotony; the ironer should be cautious, while the more "refined" lady in the dispatching department should combine lightness of touch with a pleasant manner. While there is no doubt that the accumulation of these data may bring to light many interesting facts, we are glad to see at the end of the report a suggestion to the vocational adviser that he will more often be helpful to a child if he tells him the kind of process he ought to seek than if he advises definitely one particular occupation. Most of us have known school "duffers" who afterwards, on their own vocational selection, became eminent men. Until occupation analysis becomes an exact science it will be well to leave even the elementary school child of 14 as many loopholes as possible for private vocational selection.

THE NOMENCLATURE OF TEETH.

THE British Society for the Study of Orthodontics recently appointed a committee to consider the present systems of nomenclature in use and to submit proposals for their rectification. The committee's report was presented to a recent meeting of the society by Mr. Norman Bennett. It would sanction a large number of terms for general use, together with alternative terms in a few cases, and reject others which are equivalent but are unsatisfactory or confusing. The term "cervix," for example, as one of the divisions of a tooth is adopted, with "neck" as an alternative; but the terms "fang" and "prong" are rejected in favour of "root" and "apex." The committee found some difficulty in defining the orthodontic term "vault." The definition ultimately framed was "the longest palatal border obtainable through a coronal section of a maxilla," and the term "transpalatine arch" was rejected. A good deal of trouble also was taken over the definition of "occlusion." Ideal occlusion was defined as a hypothetical standard of occlusion based on the morphology of the teeth, and normal occlusion as that occlusion which was within the standard deviations. "Inclination," defined as "the rotation of a tooth around any transverse axis," was preferred to the Continental term "version." With regard to the nomenclature of appliances and treatment, a good deal of discussion took place over "anchorage," defined as the point of attachment at which the force of reaction produces little or no movement. It was desired, said Mr. Bennett, to avoid the fallacy of pretending that anchorage was a fixed point, which it never was. Mr. George Northcroft, also a member of the committee, who had had the opportunity of discussing nomenclature with American orthodontists at the recent conference in New York, said that he had found great difficulty in persuading the Americans that there was no such thing as reciprocal anchorage, and could not be. He had pointed out that if the United States ship *Minnesota* was anchored to the earth, the earth might stabilize the *Minnesota*, but the *Minnesota* would not stabilize the earth. The Americans, however, remained unconvinced, and in respect to appliances and treatment the British and American nomenclatures had to part company. One American orthodontist objected to the term "cheek teeth" (all teeth posterior to the canines), but Mr. Northcroft pointed out to him that it was a term used by the American anthropologist W. K. Gregory of New York, and had come into general use. The alternative term, "teeth of molar series," is, however, to be permitted, but not the term "back teeth." To his surprise the Americans accepted the term "premolar," although in former discussions they had insisted on the term "bicuspid," but with regard to occlusion they fell foul of the British terms "normal," "prenormal," and "postnormal," favouring instead "neutroclusion," "distoclusion," and "mesioclusion." They abandoned the terms "gression" and "trusion," however, in favour of "displacement," as meaning the malposition of the crown and root of an individual tooth to an equal degree and in the same direction. Some discussion took place on the term "orthodontics" itself, and it was mentioned that the original title of the society was a society for the study of "orthodonture," a term of transatlantic origin; the attention of Sir James Murray, of the *New English Dictionary*, was drawn to it, and he suggested "orthodontics," which was adopted, as it was felt that there could be no higher authority.

CANCER COMMISSION OF HARVARD UNIVERSITY.

THE fourteenth annual report of the Collis P. Huntington Memorial Hospital for Medical Research and of the Laboratories of the Cancer Commission of Harvard University covers the year ending June 30th, 1926. There was a slight fall in the number of new patients, due to the opening of other institutions with good facilities for treatment. Numerous investigations were carried on in the hospital and the laboratories during the year under review. A report issued on the course, duration, and termination of one hundred untreated cases of cancer of the breast provides a basis for the comparison of the efficiency of different methods of treatment. The advantages and disadvantages of the newer methods of electro-cauterization and coagulation have also been studied. The value of a liver diet in the treatment of pernicious anaemia was one outstanding line of research, and the relation of the number of leucocytes in the saliva to variations in their number in the circulating blood is believed to be of practical importance in determining the safety of *x*-ray treatment in critical cases of the disease. Another discovery made was that, though a certain race of mice was immune to transplanted tumours, this inherited immunity could be overcome in about 15 per cent. of cases by the addition of a small piece of sterilized flannel to the inoculated tissue at the time of implantation, thereby causing local irritation. An attempt is in progress to repeat and confirm the work of Gye and Barnard. In connexion with the free diagnosis service for the State of Massachusetts, nearly 2,000 tissue specimens of suspected carcinoma were examined during the year.

A HEALTH DEMONSTRATION.

THE League of Red Cross Societies and the Belgian Red Cross, working together, have provided the first object lesson on the health organization of an industrial town in Europe. In the United States a similar experiment had been previously carried out, but the circumstances in these two instances, as might be supposed, differ considerably. The objects aimed at were chiefly these: to complete and co-ordinate the medical and hygienic equipment of a locality, and to interest in this project all kinds of agencies concerned, including the local medical men, in an attempt to provide efficient and up-to-date treatment for all the inhabitants who might require it. The result has been that 40 per cent. of the inhabitants have availed themselves of the preventive hygienic services provided, and that the expenses have not exceeded three francs a head for each inhabitant annually. How this result was achieved, and much other interesting information, is to be found in a report[1] published in Paris by the League of Red Cross Societies, of which Dr. Claude Lillingston is an energetic

[1] Croix-Rouge de Belgique. La démonstration d'hygiène de Jumet. Ligue des Sociétés de la Croix-Rouge. Paris. 1927

officer. Jumet, which has been the scene of this first essay, is an industrial town of 30,000 inhabitants, situated some miles to the south of Brussels, not far from Charleroi. It has had a chequered past, for the neighbourhood has unfortunately been repeatedly the battle-ground of contending armies from the seventeenth century onwards, and no matter whether Austrian, French, Dutch, British, or Prussian gained the day, war always meant misery for the unfortunate inhabitants. At present it owes its prosperity to its coal mines and extensive glassworks. The foundation of the health organization of Jumet rests on the "centres de santé," which may be translated as welfare centres, with their corps of visiting nurses, familiar to us in this country as district nurses; but in its conception the centre de santé is an educative and preventive, and not a curative, institution. Jumet was selected by the Belgian Red Cross for the first experiment because its municipal authorities showed a lively interest in matters of public health. Despite this benevolent predisposition, only a very few families in Jumet could be said to avail themselves of the best and latest treatment, and the vast majority obtained only empirical and imperfect medical attention. All this is changed. Apparently the inhabitants of Jumet, like the patients of Dr. Knock, had to be told that they were ill before they would seek advice. After the establishment of clinics and hospital facilities, and the organization and mobilization of the local medical men, 6,000 (or 20 per cent. of the 30,000 inhabitants) have realized their duty and presented themselves. But these figures, large as they are, do not include the expectant mothers, the children between the ages of 3 and 6 years, or the school children, the addition of which would double the number of cases. The good results of the preventive and curative measures taken in 1925 cannot be appreciated fully for some time to come. The various means employed to bring about these results need not be described at length, but those who are interested in the application of the general principles of social hygiene to a particular foreign industrial town should refer to the very full and carefully compiled report, illustrated by views, charts, and diagrams, which has just been issued by the League of Red Cross Societies. The copy sent to us has been placed in the Library of the British Medical Association.

THE STATISTICIAN AD HOC.

IT is, perhaps, debatable whether specialized institutions should keep their own statisticians. The popular suspicion of statistics is such that it behoves the statistician to try to emulate Caesar's wife. In this belief we are not fully convinced of the validity of the conclusions arrived at in a paper on tuberculosis hospitalization[1] by Mr. Godias J. Drolet, statistician to the New York Tuberculosis and Health Association, and consulting statistician to the Tuberculosis Sanatorium Conference of Metropolitan New York. Mr. Drolet finds a striking correlation between the tuberculosis death rate in various countries and the ratio of beds available. Thus, as he rather quaintly puts it, the "beds available for each ten deaths" in New Zealand, Canada, and the United States are 9, 7, and 7. And it is in these three countries that the tuberculosis mortality per 100,000 of population is lowest. In Japan, with only one tuberculosis bed available for each forty deaths, the mortality is very high, though not so high, we note, as in Czecho-Slovakia, where one bed is available for each ten deaths. It is true that Mr. Drolet guards himself by saying that of course he does not believe that hospitalization is the only factor controlling the tuberculosis death rate. Two other factors which he admits play a very great part are general living and working conditions, and racial resistance, which he believes has been acquired through previous tuberculization of the race or group, the effects being transmissible. Nevertheless, Mr. Drolet thinks that "we must acknowledge that tuberculosis hospitalization would seem to be one of the outstanding factors throughout the world in the control of the white plague." The arguments in the article are too sketchy to enable an opinion to be formed. Mr. Drolet would like a great many more beds for tuberculosis even in the United States, and a much longer term of treatment. But he complains that no answer has been given to the questions whether tuberculosis institutions should be for educational training or for curative treatment, and whether they should treat advanced cases or only early favourable cases. He urges more study of the ultimate results rather than of "the always debatable immediate results" of treatment.

THE DEFENCE OF RESEARCH.

CONFERENCE ON ANIMAL EXPERIMENTATION.

As already announced, the Science Committee of the British Medical Association, by the instructions of the Council, is convening a conference of representatives of medical and scientific bodies in opposition to the Dogs' Protection Bill. It will be held in the Council Room of the Association's House in Tavistock Square, London, on Monday, April 4th, at 4.30 p.m. The universities, medical schools, and other medical and scientific societies have been asked to send representatives, as have the veterinary and dental organizations. The response to these invitations has been highly satisfactory and the conference promises to be a most representative gathering. The lay press also has been invited to send reporters. The chair will be taken by the President of the Association, Mr. R. G. Hogarth, C.B.E., F.R.C.S.

The main purpose of the meeting is to discuss the following three motions:

1. That this Conference, believing that any withdrawal or curtailment of the powers at present granted under licence and inspection will hinder medical research to the detriment of the health and well-being of the community, wishes to enter a strong protest against any bill which has for its object further restrictions upon experimental work on dogs or other animals.

2. That this Conference is of opinion that the existing law should be altered so as to permit, under proper provision for the prevention of pain and for efficient inspection and control, the use, for purposes of research, of some of the numerous stray and unowned dogs now taken up by the police and condemned to the lethal chamber, thus ensuring conditions which are essential to progress and physiological knowledge and to the application of this knowledge to the practice of medicine.

3. That copies of the above resolutions be sent to the Prime Minister and to the Home Secretary, together with a note of the names of those present at the Conference and of the bodies they severally represent.

These resolutions will be moved and spoken to from the physician's point of view by Lord Dawson of Penn, G.C.V.O., M.D.; from that of the surgeon by Sir Holburt Waring, F.R.C.S.; from that of the psychiatrist by Professor George M. Robertson, M.D., President of the Royal College of Physicians of Edinburgh; from that of the investigator by Sir Thomas Lewis, M.D., F.R.S.; from that of the veterinarian by Lieut.-Colonel J. W. Brittlebank, President of the Royal College of Veterinary Surgeons; and from that of the general practitioner by Dr. H. B. Brackenbury, Chairman of the Representative Body of the British Medical Association.

In the meanwhile the Divisions of the Association have been asked to approach their local members of Parliament, explaining to them the attitude of the profession in relation to the Dogs' Protection Bill, and urging them to vote against the bill on second reading.

A petition against the bill has been circulated by the Science Committee among the medical members of university staffs, medical schools, and teaching hospitals, and is meeting with a most satisfactory response.

Canada.

[FROM OUR SPECIAL CORRESPONDENT.]

THE HOSPITAL PROBLEM.

THE recent meeting of the American College of Surgeons in Montreal afforded an opportunity for full and free discussion of the hospital problem, more particularly in Quebec Province. Steady progress is being made in the survey of the hospitals in this province by the American College of Surgeons, the aim, of course, being to bring them all within certain standard requirements. The proportion of hospitals so far approved is 72 per cent. This compares with a percentage of approved hospitals in Ontario of 66.7; in Alberta of 83.3; in British Columbia of 56.3; in Manitoba of 81.8; in New Brunswick of 100; in Prince Edward Island of 100. For the whole of the United States and Canada the percentage of approved hospitals is 75.5.

The situation in Montreal as regards the support of the hospitals is still unsatisfactory. The two largest hospitals here, the Montreal General and Royal Victoria, continue to show large financial deficits each year, which are met mainly by the generosity of private subscribers. It is true that the Provincial Government has done much, especially in contributions towards buildings, and compares favourably with the other Provincial Governments in this respect. But the solution is by no means yet reached. A committee of aldermen has been formed and has devoted much time to the study of the problem, but so far we still await its recommendations. The hospital tax (5 per cent. on meals in restaurants costing one dollar or more) has been in operation for some time now, and has yielded a considerable sum; but naturally it was never expected to furnish complete relief.

A bulletin issued by the Department of Health on Canadian hospitals generally contains a census of the hospitals for 1925, and shows that there are 676 in Canada, not including those for mental patients, or sanatoriums for tuberculosis. Of these 388 are public, 259 are private, and 29 are Red Cross. The number of hospitals and beds in each province is as follows:

Province.	Hospitals.	Beds.
Nova Scotia	29	1,313
New Brunswick	20	933
Prince Edward Island	3	185
Quebec	48	4,012
Ontario	176	9,955
Manitoba...	46	2,872
Saskatchewan	115	2,247
Alberta	132	2,871
British Columbia	101	3,587
Yukon	3	72
North-West Territories	3	29
Totals	676	28,076

The report contains a map of Canada showing the location of each hospital, and this gives a vivid idea of the gradual penetration of hospital facilities to some of the most remote spots.

A similarly unsatisfactory hospital situation also exists in Vancouver. The president of the Vancouver Medical Association, in his retiring address, made a powerful appeal for the support of the profession in working out some plan by which the shortage of beds in the hospitals could be relieved. He impressed upon the local profession the necessity of having something definite to put before the public whenever legislation in hospital matters was brought up, as it seems likely it soon will be.

THE TRAINING OF NURSES.

The nursing profession generally has also had an opportunity to bring forward some of its problems for discussion by medical men. At the meeting of the American College of Surgeons mentioned, one session was devoted to discussion on nursing schools and the treatment of nurses themselves. It was fully admitted that the modern nurse has more demanded of her as regards the technical accessories of medicine, and for this reason it has been necessary steadily to expand her training. But it was also the feeling of some of the leading medical men that there was a danger of nurses being taught too much of scientific details, at the expense of such fundamentals as dietetics for instance.

Those responsible for the training of nurses emphasized the difficulties they had to meet as regards the general education of those they had to train for a profession upon which so many additional demands were being made. These demands made a good general education absolutely necessary. Consequently nursing schools were making unprecedented demands on their hospital boards. Above all, the quarters for the nurses must be as comfortable as possible, as beyond any doubt the quality of the training was becoming a severe tax on the students. It was held by one speaker that small hospitals should not have training schools for nurses unless they could be given the modern type of training. Graduate nurses should be engaged in such instances. It was also shown that the number of nurses is not increasing—partly, it was said, because of the increasing tendency towards specialization in nursing. As an instance of the trend towards more elaborate methods of training in nursing, there is the newly finished nurses' training school at the Montreal General Hospital. It had been found for some years that the living quarters and training school facilities for the nurses were quite inadequate, and indeed were in a state which seriously hampered the development of the hospital. With the very generous help of the Provincial Government (which found its complement in the devoted interest and private gifts from the governors of the hospital themselves) a combined home and training school of the most modern and commodious type has been added. This was formally opened a few weeks ago by the Premier of the province, and the tour of inspection which followed revealed a most striking wealth of detail and technical equipment for teaching. One might well have been permitted at times to ask if this was not, after all, a medical school!

England and Wales.

THE LONDON FEMALE LOCK HOSPITAL.

LORD RADSTOCK opened, on March 23rd, a new unit and operating theatre for the treatment of genito-urinary diseases at the London Female Lock Hospital, erected at a cost of £1,200. Mr. Charles Gibbs, senior surgeon to the hospital, stated that in the new ward it was proposed to treat patients with serious abdominal complications; hitherto such cases had been transferred to Charing Cross Hospital. An x-ray apparatus was still required for the unit. The new ward would also be available for the more serious operative procedures connected with childbirth, and would remedy to some degree the great scarcity of beds in London for genito-urinary diseases in women. Necessitous patients would be admitted free and other patients would be accepted who could afford to pay a small sum each week. Reference was made to the fact that the London Lock Hospital had reached its 180th year.

SUSSEX PROVIDENT SCHEME.

At the annual meeting of the Sussex Provident Scheme on March 19th it was announced that during 1926 payments amounting to £7,750 had been made to various hospitals for services rendered to subscribers to the scheme; the cost of administration had only been £493. During the year under review there had been a net increase of 1,823 subscribers and 2,493 dependants. In-patient treatment had been secured for 1,058 persons for a total of 19,290 days; 3,277 had been treated as out-patients. Since the commencement of the scheme five years previously £23,876 had been distributed to hospitals. Major P. A. S. Crawley, J.P., chairman of the Sussex scheme, commented on the difference in cost between various hospitals as regards both out-patient and in-patient treatment. He thought a considerable reduction in expenditure could be brought about by the hospitals agreeing to amalgamate their out-patient departments and to establish a general centre for out-patients near Brighton station.

FINCHLEY MEMORIAL HOSPITAL.

The medical staff of the Finchley Memorial Hospital has presented Sir D'Arcy Power, K.B.E., F.R.C.S., with his portrait to commemorate his service as consulting surgeon since the opening of the institution. Dr. T. Godfrey, chairman of the medical staff, in making the presentation, expressed the desire of the staff, now that Sir D'Arcy Power had retired from the active work of the hospital, to provide a permanent record of their appreciation of his services and of the affectionate esteem in which he was held. In acknowledging the gift Sir D'Arcy Power referred to the great interest he found in the work of the hospital and in watching its growth. He returned the portrait to the secretary, who, in the absence of the chairman and vice-chairman, accepted it on behalf of the Committee of Management for a permanent place in the board room. As a memento of the occasion a small photographic reproduction of the portrait signed by the medical staff was presented to Sir D'Arcy Power.

Scotland.

NEW REGULATIONS FOR THE EDINBURGH M.D. DEGREE.

AT a meeting of the Edinburgh University Court on March 21st, a regulation for the examination for the degree of M.D. was adopted on the recommendation of the Senatus. The object of this new regulation is to provide an examination suitable for testing either persons who have been in general practice or those who have been occupying their time in research work. The examination is to consist of two parts, a major and minor. For those who have been doing clinical work the major part will be an examination in clinical medicine, including a practical and oral examination and a written paper in medicine and therapeutics, while the minor part will be a special branch of medical science or practice professed by the candidate and to be approved by the Faculty. For those who have been doing research work or engaged in some special employment, the major part will consist of a special branch of medical science or practice professed by the candidate and approved by the Faculty, and the examination will include a practical and oral examination and a written paper in the subject proposed. The minor part for these persons will be an examination in clinical medicine. At the same meeting of the court it was intimated that a grant of £6,500 had been received from the University Grants Committee to be applied towards the extension of the University Women's Union.

POOR LAW REFORM IN SCOTLAND.

The problem of Poor Law reform was discussed by Dr. W. E. Elliot, M.P., Under Secretary of State for Scotland, at Glasgow on March 24th, at a meeting held under the auspices of the Central Division Unionist Association. The speaker said that there was no more thorny set of questions than those bound up in the words "Poor Law," and the difficulties had been accentuated of late with the crisis of unemployment which came upon the country after the collapse of the post-war boom, from which the country had not yet escaped. There was no reason, however, why Scotsmen should not grapple with this question once again. In May of last year the famous circular of the Board of Health had been issued, which was in fact a Cabinet decision, and which stated that at that time it was to be considered that the dependants of people engaged in any industrial dispute should be eligible for Poor Law relief. There had been great apprehension and uneasiness in Scotland that this was a step against national tradition. He himself considered that this apprehension was unfounded, for it was more important to remember that some reform of the Poor Law system was inevitable, and it was necessary, in the steps taken to deal with this emergency, to consider what steps would be likely to be necessary when the recasting of this fundamental social law was brought about. In England the position was more advanced than in Scotland. The essence of the proposals for Poor Law reform in England was the abolition of boards of guardians and the handing over of their duties to county and town councils. The abolition of parish councils in Scotland would require much discussion, for the parish was one of the foundation stones of the whole of their society. People should be making up their minds on the problems that would arise in the course of a year or two in Scotland, and should be able to put constructive proposals before the Government in this matter.

STANDARDIZATION OF DRUGS.

At a meeting of the Pharmaceutical Society in Edinburgh an address was delivered by Dr. J. H. Burn, director of the society's pharmacological laboratories in London, on the nature and scope of the work of these laboratories. During the first fifteen months a controversy of some fifteen years' standing with reference to the action of ergot had been settled. Attempts had been made to set up physiological standards for substances like digitalis, strophanthus, and squills, which, he said, was by no means easy. In the *United States Pharmacopœia* biological tests had been included for such substances, but experience had shown that these would require revision. Preparations of these drugs made by using a definite quantity of the drug might give very serious results. In the case of digitalis, for example, one preparation had been found twice as strong as the standard, while another was 60 per cent. below the standard. This would indicate the need to fix a standard by a biological test. The importance of this work was emphasized by the recent passing of the Therapeutic Substances Act, which schedules drugs requiring to be standardized with the greatest possible care, and he believed that the work of the society's pharmacological laboratories had already been recognized as of great practical value in this direction.

TRAINING AND CARE OF THE BLIND.

A circular has been issued by the Scottish Board of Health to town and county councils directing attention to recommendations in the third report of the Scottish Advisory Committee on the Welfare of the Blind. It is pointed out that the question of home employment should receive more attention from institutions, and that blind persons should be trained either to work in an institution or to become home workers, older entrants being generally trained for the latter purpose. Those who returned to their own homes after training should continue in the employment, and under the supervision, of the training institution under an approved scheme of assistance to home workers. Only one institution had up to the time of issuing the circular submitted a scheme to the Board of Health for outdoor employment, and the board suggests that outdoor societies for the blind, as well as institutions, should consider carefully the possibilities of undertaking or developing this service. Voluntary agencies are reminded that the grant is payable to them by the board in respect of the conduct of such schemes.

PAISLEY MATERNITY AND CHILD WELFARE CENTRE.

H.R.H. Princess Mary on March 19th formally opened the Russell Institute, a maternity and child welfare centre which had been presented to the town by the late Miss Agnes Russell of Muirfield. The Princess was received by Provost Crawford, and showed much interest in the equipment of the institute, devoting special attention to the dental, orthopaedic, x-ray, and artificial sunlight departments. Provost Crawford, in an address of welcome, said that owing to the generosity of the citizens of Paisley, the question had never arisen as to whether infirmaries and other institutions for the treatment of disease should be a charge upon the rates. The present institution was an example of this public-spiritedness, as well as a memorial erected by the late Miss Russell to the memory of her brothers Robert and Thomas, whose business and social interests were centred in the burgh. In June last Miss Russell died in London at the age of 83, just before the date on which she was to have received the freedom of the burgh.

EDINBURGH HOSPITAL FOR WOMEN.

At the annual meeting of the Edinburgh Hospital for Women and Children and of the Elsie Inglis Memorial Maternity Hospital, presided over by Dr. Isabel Venters, Lady Walker, the honorary secretary, submitted the report, which showed that the increase in the numbers attending the women's hospital and dispensaries had been remarkable. In the Elsie Inglis Memorial Hospital there had been 647 births, with 213 attended in the neighbouring district, an increase of 321 on the previous year's figure. In the Bruntsfield Hospital there had been 55 extra patients over those in 1926. In the dispensary ante-natal clinic there had been 3,595 attendances, an increase of 1,524, while there had been 4,546 attendances at the newly developed child welfare clinics. In the venereal diseases clinics the numbers attending had reached 5,680, an increase of 854 on those of the previous year. The ordinary expenditure had amounted to £12,079, and the receipts to £9,300. The cost per bed in the Bruntsfield Hospital worked out at £143, which was £7 less than the figure for last year.

SMALL-POX IN DUNDEE.

An outbreak of small-pox in Dundee has occurred, and by March 25th the total number of cases was reported to be 19. The Lord Provost has issued an appeal to the citizens on the subject of safeguarding themselves by vaccination or revaccination against the spread of the disease. It is noteworthy that all the persons who had taken small-pox in Dundee are children of school age who had not been previously vaccinated.

THE CHURCH AND MEDICINE.

The annual meeting of the Church of Scotland Deaconess Hospital was held in Edinburgh on March 25th. The Rev. Dr. Norman Maclean, Moderator-Designate of the Church of Scotland, presided. Lord Sands, chairman of the board of management, submitted the annual report, which showed that a total of 6,912 persons had received the benefits of the hospital during the past year. The patients had mainly been drawn from Edinburgh, Midlothian, and Linlithgow, but a considerable number had come from various distant parts of Scotland. The speaker pointed out that 1926 was the first year in which the hospital had been faced with a deficit (£1,135) on the year's working. This, however, had been adjusted, leaving only a net adverse balance of £97 to be carried forward, but the board desired to call attention to the fact that they were responsible for providing an income of over £6,000 a year to the hospital. They trusted that the Church would respond, though no doubt the real cessation of their anxieties in regard to funds would be the permanent endowment of all the beds, towards which considerable progress had already been made. The chairman, in an address, said that there was no more beneficial type of work than that done by this hospital in a crowded district like the Pleasance of Edinburgh. He considered that medical men at the present day did not sufficiently study the history of the development of their own profession. The Church was the mother of all hospitals, for at the Council of Nicea in 325 A.D. an instruction was issued that in all cities there must be a hospital for poor and infirm pilgrims. At the present day there were scores of hospitals in France which went back to the ninth, tenth, and twelfth centuries. The Deaconess Hospital was a witness in the midst of Edinburgh to the rock whence all hospitals had been hewed, and when Church union came he thought there would be no more adverse balances, for they would have double constituencies to which to appeal. Mr. A. Logan Turner, F.R.C.S., President of the Royal College of Surgeons, Edinburgh, moved the adoption of the report, which was seconded by the Rev. Dr. Bogle, secretary of the United Free Church of Scotland. The latter remarked that the relation between the Church and Medicine had fluctuated in the course of history, for in the Middle Ages there was no separation between the two professions, and this tradition had survived in many respects. He was afraid, however, that the study of history was not pursued in the medical profession as it might be, and that very excellent traditions were losing much of their force because of ignorance of their origin.

Ireland.

ROYAL VICTORIA HOSPITAL, BELFAST.

THE 134th annual meeting of the Royal Victoria Hospital, Belfast, was held in the King Edward Memorial Hall of the hospital on March 18th. The Prime Minister of Northern Ireland, Lord Craigavon, occupied the chair, and there was a large attendance. The chairman congratulated all concerned on the most satisfactory character of the report, which reflected the highest credit upon the management. The accommodation for both intern and extern patients had been increased by 25 per cent. a year ago; £130,000 was expended out of capital, which meant a depletion of income of nearly £7,000 a year. In addition there was the increased cost of maintenance; so that a sum of about £1,200 was needed to meet the weekly expenditure. And yet at the end of a year characterized by profound depression in local industries and extensive unemployment the account closed with a debit balance of only £1,729. The systematic weekly contributions from workers' committees reached the splendid total of £19,067. Treatment to-day, with all its numerous specialties and research, was very much more expensive than in the past, and yet strict but not undue economy had brought a decrease of £14 in the yearly cost per bed. Lord Craigavon expressed the great regret that all felt that Professor Lindsay, who had been chairman of the board of management for eight years, and had been connected with the hospital in various capacities since 1883, was now retiring. He moved a resolution of thanks to Professor Lindsay for the admirable manner in which he had occupied the chair of the board of management and his devoted attention to the welfare of the hospital. Professor Lindsay was to be succeeded as chairman by the Marquess of Dufferin and Ava. The motion was seconded by Mr. R. E. Herdman, D.L., chairman of the Harbour Commissioners, supported by the Marquess of Dufferin and Ava, and passed with acclamation. Mr. Howard Stevenson, F.R.C.S., honorary secretary of the Medical Board, moved the adoption of the report of the medical staff, and drew attention to the increasing number of those seeking medical advice and treatment at the hospital; all did not realize that the institution was now a congeries of small special hospitals or units, each of which had special work to perform. Sir Thomas Houston, M.D., who seconded, praised the splendid team work carried on. An extension was needed to meet the requirements of people of moderate means, who could not pay the fees incident to private hospitals. He referred with gratitude to the donors of blood for transfusion, but said the list was not large enough yet. A vote of thank to the medical, surgical, dental, and nursing staffs for their services during the year was passed unanimously. Professor Lindsay moved a vote of thanks to the Prime Minister for presiding, and congratulated him on the honour which had lately been conferred on him; the motion was received with applause, and Lord Craigavon briefly replied.

MAJOR J. A. SINTON, V.C., I.M.S.

At the spring congregation of the Queen's University of Belfast, on March 24th, the honorary degree of D.Sc. was conferred on Major Sinton, V.C., I.M.S. The Vice-Chancellor said that Major Sinton's distinguished undergraduate career was followed by one equally distinguished in the study of the science of his profession, and by the highest honour in the field. Major Sinton was received with great applause by the audience, and will have the heartiest congratulations of all who know him. Major Sinton, after holding the offices of house-surgeon and house-physician at the Royal Victoria Hospital, Belfast, was Riddell demonstrator in pathology in the University.

STILLORGAN CONVALESCENT HOME, CO. DUBLIN.

The annual report of the committee of management of the Stillorgan Convalescent Home for 1926 stated that the good work it did had been well maintained. The number of patients admitted during the year was 607. The income

for the year was £2,575 17s. 6d., and the expenditure £2,785 0s. 11d. The extremely high level at which food, fuel, etc., had to be purchased hampered the committee considerably in carrying on the work of the home. In proposing the adoption of the report at the annual meeting Dr. T. Gillman Moorhead, who presided, said that, despite the continual improvement in sanitary conditions, a better system of town-planning, and an improvement in the health of city populations, the larger number of city workers were, as regards health, only C3 instead of A1. In that lay the importance of treatment in the country. At the Stillorgan Convalescent Home the patients got good food, fresh air, and, in particular, plenty of sun. Six to eight hundred city workers were treated annually in this home, and since it was founded, sixty-five years ago, nearly 50,000 people had been treated. Dr. Moorhead referred to the revolution that had taken place in the finances of hospitals in the last ten or twelve years. With the war came higher costs for foods and drugs, and subscribers could not afford to increase their donations in proportion; so the patients who could pay were asked to contribute. During the last twenty-five years, Dr. Moorhead added, no patient recommended by him for the home had been refused. Again and again he had received letters from patients telling him of the benefit that they had derived from treatment at the home. He himself was firmly convinced that, from a medical point of view, convalescent homes were most necessary for the complete return to health of city workers who were recovering from a severe illness. He thought that the public were beginning to wake up to this fact.

Correspondence.

THE USE OF TUBERCULIN.

SIR,—Judging by recurrent references in the press, medical and lay, it would seem that the subject of tuberculin is regarded by many persons as a *terra incognita* which had hardly been explored save by a handful of adventurers who recounted their experiences in not strictly measured language. Is this really the case? Speaking as one who has used tuberculin much and consistently since its introduction in 1890, both for treatment and for diagnosis, I am puzzled to understand the difficulties frequently expressed.

For the last ten years the University of Edinburgh has included in its medical curriculum special training in tuberculosis. The course, which means thirty meetings, is very practical, and is compulsory on all students preparing for graduation. The subject has special consideration in the Final Examination. During the course, which deals with tuberculosis as a general infection and as it manifests itself in the various organs of the body, the properties and value of tuberculin, and the various methods of use for purposes of diagnosis and treatment, are discussed at length and richly illustrated by the exhibition of patients, etc. For tuberculin is in daily use, in one or other fashion, in the several medical institutions which are linked up with the University Department. As the University turns out an annual average of approximately two hundred medical graduates, the number of younger practitioners in Britain and the Dominions who have knowledge of the subject must be very considerable.—I am, etc.,

Edinburgh, March 26th. R. W. PHILIP.

INFLUENZA AND THE HEART: ADMINISTRATION OF RAW ADRENAL GLAND.

SIR,—In your leading article on "Influenza and the heart" (March 19th, p. 527) you speak of the low systolic pressure that characterizes the aftermath of influenza, and after discussing the parts played by the poisoned heart muscle (Dr. Shore's observation in 1918) and by the poisoned vasomotor mechanism (degenerated internal elastic layer and muscle of the media of vessels: Stoerk and Epstein, 1919), you come to Cowie and Beaven's suggestion (1919) that the suprarenal glands are damaged, or, at any rate, fail to function properly, as a result of the influenza poison. "But," you say, "the advantage that has been claimed for treatment with adrenaline and other similar methods has received no great measure of confirmation."

I have not tried adrenaline. I do not know how to use it for a chronic condition. But I have used raw adrenal gland and I find it effective.

For instance, on March 17th a nurse, aged 50, is noted as having a systolic pressure of 92. "I feel good for nothing," were her words, "and don't care what becomes of me." After treatment by raw adrenal gland, and by nothing else, the pressure on March 22nd was 116, and she was bright and fit for some portion of her duty.

Again, a horseman, aged 22, recovered from exceptionally severe and neglected influenza, is noted on March 22nd as "weak," and having a blood pressure: systolic 112, diastolic 68. He takes four pieces of raw adrenal gland in the next twenty-four hours, and has no other treatment. Next day (March 23rd) he "feels much better, much more like doing a day's ploughing," and his pressure is systolic 122, diastolic 72 (mercury instrument, and auditory method).

My experience of using the raw gland is too recent and limited for dogmatism; but I think it works. And I think so with the more confidence because I have had considerably more experience of the use of raw adrenal gland in another condition, asthma. In cases of chronic and intractable asthma, resistant to other treatment, I have convinced myself by a good many months' trial of the reality of the good effect of raw adrenal gland. But that is another story—a story I hope to tell more formally, at more leisure. Your leader constrains me to mention now this simple observation:

If a sheep's adrenal gland, which is a little thing like a reddish-brown bean, or tiny kidney, about an inch long, be cut into six pieces across the length, so that each piece contains both cortex and medulla, and if one such piece be taken, raw, in a teaspoonful of cold water, or in a bit of bread, on an empty stomach, thrice daily, by the patient with post-influenzal debility, the headache and the lassitude clear up and the patient soon approaches normal health.

I must add three notes in a minor key:

(1) I have mentioned asthma. A bit of adrenal gland is disappointing when an attack is on. It will not stop the attack. All I find is that chronic asthmatics, to whom other treatment designed to remove the provocative cause is being given without success, or with very incomplete success, improve when they take the raw gland. Attacks tend to recur when they stop taking it. I hoped that the sheep's gland would awaken the patient's own adrenals to activity. My evidence on that point is incomplete.

(2) One asthmatic patient, on taking about a third of a gland in a single dose, gets distressed. There is nausea and a sense of apprehension. For half an hour the symptoms are severe. This patient, however, persists in taking the gland in small doses because "she keeps freer from asthma when she is taking it."

(3) One post-influenzal patient, after experiencing rapid relief from lassitude during several days in which she took the gland, then had a bilious attack (that is, felt sick and distressed). That soon passed.

I have seen no other ill effects of the use of this remedy (unless a transient attack of gout was due to it, in a patient strikingly relieved by a course of raw gland from the influenzal aftermath). But doubtless any extended use of it should be safeguarded by watchfulness lest haply it provide glycosuria.

There is one thing to add. Sheep's adrenal keeps worse than almost any other part of the carcass. One butcher I know removes the glands "to prevent the meat going bad."

The doctor who uses this remedy will have to find the glands for himself—in the fat above the kidney and not so close to that organ as human anatomy would lead him to expect. The butcher sometimes knows them (some do not), but has no name for them.—I am, etc.,

Holmes Chapel, Cheshire, March 25th. LIONEL JAS. PICTON.

SPASTIC PARAPLEGIA.

Sympathetic Ramisectomy.

SIR,—Most of us who read the first accounts of sympathetic ramisectomy were under the impression that this operation was the outcome of the theoretical, experimental, and clinical work of Drs. Hunter and Royle, and we understood that, while Dr. Royle was concerned more with the experimental and clinical side of the question, he associated himself also with the views, anatomical and physiological, expressed by Hunter. Hunter quite definitely put forward the hypothesis that the functions of movement and posture are performed by entirely different sets of muscle fibres—an hypothesis which in the present state of our knowledge I venture to think cannot be supported.

When I recounted my own small experience of sympathetic ramisectomy to the Neurological Section of the Royal Society of Medicine on February 11th, 1926, I made a few introductory remarks which I did not then think worth elaborating in the *Proceedings* of the society.

For a long time I had been attracted by the hypothesis of the dual innervation of skeletal muscle, and soon after Sherrington's paper on the postural activity of muscle appeared in *Brain* in 1915 I began to make some experiments to see whether division of the sympathetic nerves would have any effect upon the spasticity of hemiplegic limbs. In an anatomy book I found a picture of the brachial plexus receiving a spray of communicating branches from the first dorsal ganglion of the sympathetic and some also from the inferior cervical ganglion, and I was then under the impression that at least a considerable part of the sympathetic nerve supply of the upper limb was derived from these branches. In a typical case of infantile hemiplegia in a youth I removed the first dorsal and inferior cervical ganglia with all their branches. This operation was followed, of course, by paralysis of the cervical sympathetic on that side, but it had not the slightest effect upon the muscular tone or the vascularity of the upper limb.

I was then reminded of the work of Wood Jones, who showed that the communicating branch from the second dorsal nerve to the brachial plexus is composed almost entirely of sympathetic fibres, and he suggested that the vascular symptoms which occur in some cases of cervical rib might be due to pressure upon these fibres as they join the lowest cord of the plexus lying upon the rib. I therefore, in another case of infantile hemiplegia, excised the communicating branch from the second dorsal nerve and also the first dorsal ganglion with its branches. This operation also had no effect upon the muscular tone or the vascularity of the upper limb.

I then turned to Leriche's operation of stripping the tunica adventitia, and with it the periarterial sympathetic plexus, from a section of the main artery of a limb. On theoretical grounds this operation never appealed to me, because I thought that one of the few things we did know about the peripheral distribution of the sympathetic was that the arterial nerve supply is segmental and the periarterial plexus does not in any sense constitute a tract running along the artery to supply the distal parts. I have done Leriche's operation only once, and that was on the brachial artery of a woman with typical hemiplegia, and it had no lasting effect upon either the muscular tone or the vascularity of the limb. I have seen a few other cases in which either Leriche's operation or the injection of alcohol into the sheath of the artery had been done for one reason or another, but I have never seen any permanent effect from either procedure.

It was therefore with great interest that I read the first accounts of Hunter and Royle's work as soon as they were available, and I believe I was one of the first to try the operation of sympathetic ramisectomy in this country, my bias (if any) being all in favour of confirming Royle's results if possible.

But before attempting my first case I had already heard some criticism and counter-criticism of the operation. The defence bluntly amounted to this—that those who had done the operation and had failed to obtain results similar to those of Royle were either careless neurologists who could not recognize the plastic tonus described by Sherrington, or they were incompetent surgeons who thought they had divided the sympathetic rami, but really had not.

I was determined that criticism on these points at least should be out of the question. The cases selected by me were examined by some of the best known neurologists in this country, and they were chosen particularly from the point of view of showing the effect of sympathetic ramisectomy on plastic tonus. The operations themselves were conducted with extraordinary care and deliberation as "demonstration" operations in the presence of highly qualified and very critical assistants. Every step in the operation was verified. When the rami and the sympathetic trunk (in the lumbar operations) had been exposed, a pause was made and these structures were both demonstrated by myself and examined independently by my assistants, so that there should be no possible question of their identity. Each ramus was then picked up in turn, called by name, and when everyone was agreed upon its identity, it was divided in view of those assisting me; and similarly with the lumbar trunk. No case in which there has been the slightest doubt as to the destruction of the sympathetic rami—and the correct ones—has been included in my small series.

I hope that before long Dr. Royle will be able to demonstrate to us here in London that sympathetic ramisectomy produces not only constant results but more pronounced results than were obtained in any of my cases; for I have to confess that even in the "about half" of my cases which gave a positive result the rather slight diminution of muscular tone which followed the operation did not appear to me to be of great benefit to the patients.—I am, etc.,

London, W.1, March 28th. A. S. BLUNDELL BANKART.

CATARRHAL VACCINES.

SIR,—The value of prophylactic vaccines against the common cold and feverish chill is not yet accepted generally as proven. Though there are an increasing number of doctors who believe in and practise this method of preventive treatment, there are probably many more who are waiting for further proof of its efficacy before adopting it or advocating it in their own practice.

Evidence from the clinical side of the value of vaccines can be got through the accumulation of statistics amongst a more or less fixed population, living under similar conditions for a considerable period, and a public school does offer such conditions. In such an institution vaccines cannot be given compulsorily, but only with the parents' consent, and it will probably be found that the relative numbers of acceptances and refusals will be such as to offer a reasonable control experiment, though the word "experiment" is an unfortunate one in this connexion, so far as the public is concerned.

An attempt has been made at one public school during the year 1926 to supply this evidence. Records were kept throughout the year of every boy reporting sick with cold or feverish chill. As at this school the school hospital is the only place where a boy can report sick, the large majority of those affected to any extent are recorded; but it is recognized that some of those with colds only would not come for treatment, and to that extent the accuracy of the figures given below is vitiated.

The vaccine used in almost all cases was the anti-catarrhal vaccine supplied by Parke Davis, prepared by St. Mary's Hospital. Three doses were given at weekly intervals: to those below 15 years 0.25 c.cm., 0.4 c.cm., 0.6 c.cm., to those above 15 years 0.3 c.cm., 0.5 c.cm., 0.75 c.cm.; 170 boys were inoculated in January before returning to school, the remaining fifty in the first three weeks of the Lent term. Ill effects were trivial. Three boys reported a temperature of 100 to 101° for about twenty-four hours. Two felt faint a few hours after the first dose. One had a slight local reaction after the third dose. One reported a cold after the first two doses.

Though the total number of boys in the school remained constant throughout the year, the number of those inoculated varied, as some boys left and new ones came. The following figures therefore are given for each term separately.

	First Term.	Second Term.	Third Term.
No. of Boys in School.			
Inoculated	220	220	200
Non-inoculated	315	315	335
No. of Colds	160	35	86
Inoculated	50=22.7%	10=4.5%	18= 9.0%
Non-inoculated	110=34.6%	25=8.0%	68=20.0%
No. of Feverish Chills ...	33	17	51
Inoculated	10= 4.5%	4=1.8%	16= 8.0%
Non-inoculated	23= 7.3%	13=4.1%	35=14.4%
Days Lost	413	104	980
Inoculated	80. Av. 1.3	19. Av. 1.3	263. Av. 7.7
Non-inoculated	333. Av. 2.5	85. Av. 2.75	717. Av. 7.0
Complications.			
Inoculated (16)	2 Otitis 2 Bronchitis	1 Adenitis	1 Otitis (abscess) 6 Bronchitis 3 Broncho-pneumonia 1 Carditis
Non-inoculated (37) ...	5 Otitis (2 abscess) 9 Bronchitis 2 Broncho-pneumonia	2 Otitis 2 Bronchitis	5 Otitis (5 abscess) 2 Bronchitis 8 Broncho-pneumonia 1 Adenitis 1 Pleurisy

The figures in the group of "days lost" are not quite clear. By the average is meant the days lost by those who had colds or feverish chills in the two groups. If the average of days lost was taken amongst all the inoculated and non-inoculated it would, of course, be very different, and for the whole year would show:

Inoculated	0.36, 0.09, 0.76
Non-inoculated	1.0, 0.26, 2.1

From this aspect the loss of time was nearly three times as great amongst the group of non-inoculated as amongst the inoculated. The rest of the figures show a slight but definite advantage for the inoculated. To the observer this advantage was the more noticeable as regards the complications, the severity of which was much more marked in the non-inoculated.

Another point which cannot be shown statistically is that amongst the inoculated were the large majority of those known to be particularly susceptible to colds and coughs; this would tend to raise the percentage incidence of this group, but observation showed that these "inoculated susceptibles," if attacked by cold or catarrh, were definitely less affected than might have been expected from their previous record and medical history at the school. The suggestion is that their immunity was raised. It will be noted that the complications were more numerous and more severe in the winter term, and the average loss of time very much greater. No doubt the small amount of sunshine during the late autumn delayed convalescence, but it is not unreasonable to suggest that the hypothetical good effects of the vaccine given in January had passed away. Certainly the Lent term was very healthy, and never had the colds and coughs been so few or so slight, and never had so little medicine been used.

During the year 1926 the Medical Officers of Schools' Association issued a circular to a large number of schools on the subject of catarrhal vaccines, and through the kind help of the authorities of the bacteriological department of St. Mary's Hospital got prepared a special "school vaccine" from a large number of swabs sent up from schools in various parts of the country.

This special vaccine was put on the market in December last by Parke Davis, and it is hoped that sufficient use will have been made of it during this year to form an opinion as to its value.—I am, etc.,

March 28th. L. R. LEMPRIERE, Medical Officer, Haileybury College.

HEREDITARY FAMILIAL CONGENITAL HAEMORRHAGIC NEPHRITIS.

SIR,—In his paper, published in the JOURNAL of March 19th (p. 504), Dr. A. Cecil Alport adds some interesting details to the history of the family first described by Leonard Guthrie in 1902 and subsequently by me in 1912. Unfortunately he appears not to have seen a later paper, published in the *Guy's Hospital Reports* for 1923, which contains particulars about the members of the third generation born since 1912. In this paper I also refer to Case No. 6 as being still alive, and I record the fact that Nos. 14 and 15, said by him to be unaffected, had, as a matter of fact, suffered from attacks of haematuria. So far as I can recollect, Dr. Alport is incorrect in stating that Cases 10 and 11 were deaf.

In addition to the cases of familial nephritis collected by Dr. Alport, I referred in my paper of 1923 to three other families. Benson[1] in 1893 reported the case of four brothers and sisters who suffered from acute nephritis in a period of four years, three of whom died; Fergusson,[2] in 1910, described a family in which the father aged 87, the mother aged 78, and eight children, whose ages varied between 45 and 56, had albuminuria unaccompanied by other symptoms; and in 1920 Thomson and MacAuley[3] reported four cases of acute nephritis occurring after influenza in a family of eight children; all recovered completely.—I am, etc.,

New Lodge Clinic, Windsor Forest, March 22nd. ARTHUR F. HURST.

SIR,—Dr. A. Cecil Alport may be interested to hear of a family some members of which have been under my care suffering from haematuria of the same nature as that mentioned in his interesting article (March 19th, p. 504). Fifteen years ago I attended a woman, then aged 34, suffering from haematuria, the cause of which I did not then recognize. Last week I saw her again for the same complaint. Two years ago I was called to a male patient, aged 39, who had severe haematuria; three months later he had another severe attack. I sent him to a surgeon, who eventually removed a cystic kidney (right) weighing 8 lb. Four months after the operation he had another attack of haematuria. As far as I know he has had none since. His father died of "kidney disease." During January of this year a man, aged 46, came to see me complaining of passing blood in his water. This came on after rather a severe blow in the abdomen. There was severe pain in the right loin, but neither kidney was palpable. He was back at work in about a week. As his name was similar to that of the last patient mentioned I made inquiries as to his family history, and elicited the following facts. His father died as the result of a "seizure" seven years previously. He suffered from haematuria, having on an average one attack yearly. Three brothers, aged respectively 40, 48, and 49, all suffered from the complaint. The one aged 49 died suddenly, the cause of death being certified as "haemorrhage." Until I saw the last patient I was not aware that any of these three were related; he informed me that the first patient was his sister and the second his cousin. None of the three patients referred to suffer from deafness. —I am, etc.,

FREDERICK H. RUDGE, M.R.C.S.

Lostwithiel, Cornwall, March 22nd.

THE SURGERY OF GASTRIC AND DUODENAL ULCERS.

SIR,—In the article by Mr. H. S. Souttar in the BRITISH MEDICAL JOURNAL of March 19th (p. 501) on 1,275 cases of gastric and duodenal ulcers admitted to the surgical wards of the London Hospital in 1923-25 he says:

"Of the 1,275 London Hospital cases above referred to, 660 were gastric ulcers with a male incidence of 70 per cent., and 615 were duodenal ulcers with a male incidence of no less than 86 per cent.—figures which agree closely with those found elsewhere by both English and American surgeons."

So far as this statement refers to the male incidence I have no comment to make; but the ratio of gastric to duodenal ulcers does not coincide with our experience in Leeds. In the years 1924 and 1925 there were admitted to the surgical wards of the General Infirmary at Leeds 559 cases of chronic gastric and duodenal ulcers, of which 148 were gastric and 411 duodenal—that is to say, an incidence of 2.7 to 1 in favour of duodenal ulcer; and this

[1] A. H. Benson: *Lancet*, 1893, i, 583.
[2] J. N. Fergusson: BRITISH MEDICAL JOURNAL, 1910, i, 637.
[3] W. W. D. Thomson and H. F. MacAuley: *Lancet*, 1920, i, 431.

preponderance of duodenal ulcers over gastric has held good for many years—in fact, ever since we realized that the dyspepsia associated with haematemesis in young women is seldom due to chronic gastric ulcer. I do not think this accounts for Mr. Souttar's figures showing more gastric than duodenal ulcers, because he gives a male incidence in the former as high as 70 per cent.

There is, however, a possibility of confusing duodenal and gastric ulcers situated near the pylorus; indeed, some Continental surgeons go so far as to say it is impossible to differentiate these with the organs *in situ*. We have become accustomed to rely upon the white line of the pylorus and the pyloric vein as landmarks of sufficient accuracy to enable us to say that an ulcer to the right of these is duodenal and to the left gastric. If the London Hospital statistics are not dependent upon some such clearly defined anatomical differentiation between what is gastric and what duodenal, I can see a good reason for the discrepancy between their recorded results and ours. It is difficult to believe there is really so marked a difference between the localization of ulcers in the north and south of England.—I am, etc.,

Leeds, March 27th. E. R. FLINT.

MALIGNANT DISEASE OF THE THROAT.

SIR,—I heartily agree with Mr. Syme (March 19th, p. 540) that it is much to be desired that patients suffering from, or suspected of, cancer of the throat should see the throat surgeon at as early a stage as possible. I do not think, however, that the general practitioner should bear the entire blame for such belated attendance and for the advanced condition of many cases when first seen by the specialist, since the patient himself is often most remiss and dilatory in going to the practitioner, even delaying until the malady has drifted on to an inoperable condition.

During the last three months I have met with two cases—both in men of over 60 years of age—which plainly point to the dangers, not only to the patient, but to the public. Both were brought at once by their doctors for confirmation of their diagnosis, and were suffering from advanced cancer of the throat, but had been so careless and ignorant that one had arranged to be married at an early date, and the other had been regularly partaking in church of the Holy Sacrament.

My experience is that there has been during recent years a greatly increased vigilance and correctness of diagnosis on the part of the general practitioner; this, I think, is certainly an outcome of greater facilities for post-graduate study, and the pressing and efficient way in which medical journals and literature have emphasized the urgency for improved knowledge on the doctor's part.

With regard to lay enlightenment, however, much yet remains to be accomplished, and I would urge the imperative necessity for an extension of such measures as were recently mentioned by Sir Berkeley Moynihan for starting in Yorkshire itinerant vans with lecturers to give demonstrations all over the country to teach the laity. Lectures might also be delivered by the junior members of the staff of both general and special hospitals on the prevention of disease.—I am, etc.,

London, W.1, March 27th. WILLIAM STUART-LOW, F.R.C.S.

PHARYNGEAL DIVERTICULA.

SIR,—It was my privilege in my earliest days in the dissecting-room to see the dissection of the historic pharyngeal diverticulum described by Morison Watson. I trust my sentimental, in addition to my technical, interest in it may justify my trespassing on your space. It was unquestionably pharyngeal, and air may have entered it in sufficient quantity to give it some claim to the title of aerocele. It is highly improbable, however, that food could have done so in sufficient quantity to cause much distension, in view of the small size of the opening. To my mind it was more likely to be produced by the entrance of pharyngeal secretions, and I think the term "pharyngocele," or Watson's non-committal one of "pharyngeal diverticulum," is the most appropriate. It was no doubt originally a small congenital defect in closure of the second branchial cleft, distended by the accumulation of air and secretions, and, therefore, eventually a pressure pouch.

Godlee's case is more obscure, and the tracing of the pedicle to the thyro-hyoid membrane in association with the increase of swelling when the subject "held his breath and blew," would suggest at first glance a laryngeal origin. It is difficult to give a definite meaning to the somewhat loose expression "held his breath and blew," but with goodwill it might be interpreted to signify that he closed his larynx (by means of the ventricular bands) and made an expiratory effort, or that he closed his lips tightly (with or without pinching the nostrils) and then "blew." Swelling in the former condition would indicate a laryngeal communication, while in the latter it might be pharyngeal. The fact, however, that salivary glandular structures (described with minute detail) were found in the wall of the sac when vouched for by Godlee (and for any who knew him this is conclusive), proves beyond question that the cavity was originally, at least, of pharyngeal origin.—I am, etc.,

London, W., March 25th. JAMES DUNDAS-GRANT.

SIR,—In my letter of January 8th I pointed out that Dr. Irwin Moore was obviously wrong in asserting that the case of pharyngeal pouch so carefully recorded by Godlee and Bucknall was really a laryngocele. The marked dysphagia, the uncomfortable sensation shooting up to the ear on squeezing the sac, and the presence of glands "representing in every detail of their structure a mucous salivary gland," as found in several other cases of pharyngocele, clearly established the fact as claimed by Godlee and Bucknall, that their "pouch was obviously of the pharyngeal variety." The presence of salivary gland tissue alone knocks the bottom out of Dr. Moore's argument that the pouch was laryngeal and not pharyngeal. Dr. Moore now brings forward a "somewhat dramatic story" which he got from Sir Arthur Keith, from which it appears that the latter wrote to Godlee pointing out that the description left no doubt that it was a laryngeal air sac, and that Godlee replied accepting this view. Dr. Moore claims that this settles the question in his favour. It does nothing of the kind, in my opinion, and, moreover, the story has a sequel. Soon after the publication of Halstead's paper in 1904 (*Annals of Surgery*) on diverticula, in which the case under discussion was quoted, I met Godlee and talked the case over with him. He then said nothing about his having abandoned the idea that the air sac was pharyngeal (so that his conversion must have been short-lived and forgotten); but, on the contrary, he pointed out with enthusiasm his gratification that Bucknall (who was responsible for the pathological and literary research part of the paper) had been able to collect at least one British case, similar to theirs, in addition to half a dozen foreign ones (Kostanecki, *Virchow's Archive*, vols. 117, 120, 121). We can fairly conclude that though Godlee was temporarily converted by Sir Arthur Keith to admit the laryngeal origin of the sac to begin with, yet that, on conferring with Bucknall, he reverted to his original explanation of the case, otherwise he would surely have written a correction to the *Lancet*. This case must stand as reported.

Of course, it does not fit in with Dr. Moore's thesis to admit that Watson's case of pharyngeal diverticulum, of presumed branchial origin, was a pouch containing air, so he falls back on the generalization of Keith, that as it originated behind the thyro-hyoid ligament it could not contain air, and Dr. Moore now states that it was a "dilated branchial cleft sinus with a dilated saccular or cystic extremity." The use of the word "cystic" suggests that Dr. Moore is trying to make out this specimen of Watson's to be a true cyst, whereas the clear description of the case shows plainly that it was an undoubted air-containing pouch with a well defined mouth in the faucial region, and not a mere potential space or sinus, nor a cyst. Watson states that the sac terminated "inferiorly in a dilated cul-de-sac, which on being cut discharged a quantity of grumous material"; such material is often found in the cavities of the mouth, pharynx, and oesophagus in dissecting-room subjects, and is not a cystic content. Bland-Sutton, in his Erasmus Wilson Lecture in

1887 (*Journal of Anatomy*), quotes this case as a pharyngeal pouch of congenital branchial origin, and makes no suggestion of its resembling a cyst. This case also stands to controvert the view of Keith and Moore that all cervical air sacs are laryngeal in origin.

As regards Wheeler's case, the description clearly identifies it as a pouch containing only air during the time the patient was under observation and at operation. Dr. Moore asserts that it was a "pressure diverticulum or pulsion pouch." All pouches, without exception, originating from the pharynx must develop by pressure (pulsion), whether congenital or acquired, but some develop through air pressure alone, and others by food pressure combined with air pressure. The evidence that it was not congenital but acquired, and caused by food pressure, or ever at any period contained food, is wanting, though possibly this may have been so, as also may have been the case in the St. Thomas's Hospital specimen, which was figured by Butlin in his communication to the Royal Medical and Chirurgical Society in 1893. I showed a slide of this to illustrate my paper at Nottingham. I admit an element of doubt as to these two cases being pure aeroceles, because of their wide orifices, though their lateral position obviously suggests a congenital branchial origin.—I am, etc.,

London, W.1, March 26th. WILLIAM HILL.

*** Although we had considered that this correspondence had come to a natural end, we feel bound, in justice to Dr. Hill, to publish the above letter, and Sir J. Dundas-Grant adds an interesting reminiscence. We cannot undertake to publish other letters on the same subject.

INFLUENZA AND ALBUMINURIA OF PREGNANCY.

SIR,—Mr. R. H. Paramore, commenting in your issue of March 26th (p. 596) on Dr. Gutch's suggestion (BRITISH MEDICAL JOURNAL, March 19th (p. 543) that influenza and the albuminuria of pregnancy stand to one another in the relation of cause and effect, brings forward a very ingenious mechanical explanation for the cause of the albuminuria when it affects pregnant women during the influenza epidemics, but, unfortunately for his theory, it is based on two wrong assumptions at the outset—namely: (1) That, as Dr. Gutch says, "the pregnant woman only is affected in this way," and (2) that a "terrible cough" (as Mr. Paramore says) is present in these cases. Now, any general practitioner who has a wide experience of influenza knows that not only pregnant women, but non-pregnant women, men, and children of both sexes and all ages are "affected in this way"—that is, are liable to renal complications during the influenza epidemics or, indeed, at any time following an attack of influenza. The following extract from an essay on "Influenza in general practice," which I wrote about eighteen months ago, may be of interest.

"I have noted during the epidemics and in the intervals many cases of pyelitis which were undoubtedly due to influenza; as I am writing this I have a small epidemic of pyelitis, and every case can be attributed to a definite influenza with sore throat, which occurred about fourteen days before the onset of the renal symptoms; it is much more common for the tonsillar cases to be so complicated than those with pulmonary symptoms. I have noted, too, far too frequently for the matter to be considered a coincidence, that pregnant and puerperal women show a decided tendency to pyelitis during the epidemics, and I am convinced that the pyelitis of pregnancy is sometimes influenzal. . . . There is no doubt in my mind of the existence of an influenzal nephritis; I have seen many cases; here, again, the influenza with sore throat is most commonly antecedent."

These statements were based on a study of over 1,700 cases which had been on my visiting lists, and subsequent experience of many more hundred cases has more than justified my remarks. Like Dr. McDougall, I am "surprised that this is not more generally recognized."

Mr. Paramore, however, may not be satisfied with my experience, so I refer him to a short article by Peace (BRITISH MEDICAL JOURNAL, January 2nd, 1926, p. 17), who described some cases of "nephritis following tonsillitis," and another by Cook (BRITISH MEDICAL JOURNAL, December 11th, 1926, p. 1118), on some cases of "acute haemorrhagic nephritis following influenza." There is no mention of pregnant women in either article.

I hope, therefore, that Mr. Paramore will recognize that there are two fallacies in his argument: (1) That the nephritis is not confined to pregnant women. (2) That nephritis follows influenza oftenest when there is no cough, and therefore is *not* the "enormous rise of pressure in the abdomen" of which Mr. Paramore speaks.

I remember seeing in consultation in February, 1923—when influenza was fairly prevalent—a woman in the puerperium who had a high temperature which had failed to react to the uterine douche applied on several occasions. I suggested that the fever was renal in origin, and a microscopical examination of the urine showed it to be teeming with *B. coli*. Potassium citrate brought down the temperature promptly. I also remember an infant of 10 months whom I had seen in my surgery with an influenzal tonsillitis, developing pyelitis a week later; the mother and father were down with influenza at the same time. Here again the condition cleared up with potassium citrate. One reads much of pyelitis being mistaken for influenza. Though the renal changes are often overlooked, they often follow influenza. The influenza germs or toxins must have an effect on the kidney and render it vulnerable to attack by the germ which is constantly in the vicinity—the *B. coli*.

I am not so sure that, as we become more enlightened, we will not find that accidental haemorrhage, eclampsia, etc., are due to the invasion of the body by extraneous organisms of the influenza family, and that there will not come a time when it will be no longer considered old-fashioned to make a diagnosis of influenza during the puerperium. Browne's recent work on placental infarction in connexion with accidental haemorrhage has paved the way for other observers.

A case of that rare complication—suppression of urine after labour—which I reported in the BRITISH MEDICAL JOURNAL of April 14th, 1923 (p. 630), puzzled me at the time. I found out later that I had attended the woman's father in the same house during the same week for influenza with severe delirium and that the puerperal pyelitis case mentioned above was seen in that week. Were these coincidences? I am inclined to think now that influenza had something to do with the suppression.

I suggest that a far more reasonable explanation than Mr. Paramore's of these cases is that they are embolic. I have seen two cases in the last twelve months of nephritis following influenza in which pulmonary infarction followed the nephritis. There is, of course, no reason why the pregnant woman should not be "affected in this way."—I am, etc.,

Aberdare, March 28th. AMBROSE W. OWEN.

SIR,—Mr. Paramore (BRITISH MEDICAL JOURNAL, March 26th, p. 596) attributes the relation between influenza and albuminuria in pregnancy to pathological intra-abdominal pressure. But surely the large bed of fat in which the kidney lies is sufficient to act as a shock absorber. I am quite ready to allow that in pertussis albuminuria is fairly frequent, but naturally most of the observations have been made in children, in whom the fatty bed is not so well developed. Normally great changes occur in the blood during pregnancy—for example, the great reduction in the suspension stability of the red blood corpuscles. It is not unreasonable to expect that the further changes provoked by an infection with the influenza bacillus will occasion such a degree of condensation in the protein particles of the blood that the glomerular membranes will permit the altered protein particles to pass through into the urine.—I am, etc.,

Bristol, March 28th. FRANK BODMAN, M.B.

SPORADIC DYSENTERY IN ENGLAND.

SIR,—The very interesting account in the JOURNAL of March 26th (p. 563) of outbreaks of bacillary dysentery prompt us to send a brief note of a similar small epidemic which occurred three weeks ago in an institution under our medical charge.

[1] McDonagh: *The Nature of Disease*, vol. I, 133.

The outbreak occurred, fortunately, in a small group of children who were at the time isolated in the sanatorium of the institution on account of whooping-cough. The first case, a boy of 4, started with a temperature of 102° F. and profuse diarrhoea, with green stools. In the course of a few hours this changed to blood and mucus. The tenesmus was very severe, and the child was passing small portions of blood and mucus about every twenty minutes. Treatment consisted of a preliminary dose of castor oil and subsequently small doses of Dover's powder. Two days afterwards two other children of the same group developed it, and two days later another two, and two adults who had been in contact with the sanatorium had slighter attacks. The original case is still passing occasional mucus, but all the other cases cleared up in a week. They all started with temperatures of 102° to 103° F. In the case of the youngest children the treatment as in the first case was adopted, and with the older and adults magnesium sulphate was given every two hours, until the motion became normal.

Immediately on the onset of the outbreak the sanatorium was strictly isolated from the main building. All motions were disinfected, and a kitchen was established for the use of the sanatorium alone. No fresh cases occurred either in the sanatorium or in the main building. In view of the possibility of the organism being dysenteric, specimens of the motions were sent direct by car, forty miles, to the nearest laboratory. Four of the cases gave a culture of *B. dysenteriae* "Y." In regard to the origin of the outbreak, water and milk were excluded, and no food had been consumed in the sanatorium which was not common to all the institution.

The matter is still under investigation, but two possible sources have been determined. (1) A visitor to the institution proves to have just returned from abroad convalescent from dysentery, although the type has not yet been discovered. This visitor was in close contact with the original case. (2) The original boy was born and spent nearly two years in India. He may prove to be a carrier.

We should like to express our indebtedness to Dr. J. J. Day, medical officer of health, Eastry area, and Dr. Ponder, Kent county pathologist, for their valuable help in dealing with this outbreak.—We are, etc.,

N. MCCALL-SMITH,
D. M. M. FRASER.

Eastry, Kent, March 26th.

BREATHING EXERCISES WITH MOVING ARMS.

SIR,—Mr. R. H. Paramore, F.R.C.S., in his letter (March 19th, p. 542), commenting on my article (March 5th, p. 422), asks, "Can the doctrine of the reciprocal innervation of antagonistic muscles stand?" This doctrine is generally accepted, and I personally find evidence of it in the healthy man in physical training.

The tension in the opposing muscles described by Mr. Paramore is due to the contraction of the plastic element in the muscle, consisting of the thin muscle fibres of a voluntary muscle innervated by the sympathetic non-medullated nerves, and has nothing to do with the contractile element, which consists of the thick fibres of the muscle innervated by the somatic medullated nerves. The plastic element is merely postural, and does not oppose.

Pulling on the arms in artificial respiration cannot very well be an illustration that movements of the arms raise the ribs, for in this case the arms are passively moved, whereas I speak of actively moving arms. Even in this case artificial respiration depending on passive movements of the arms has been given up for better and more efficient methods.

The only time when the muscles attached to the chest and arms can raise the ribs is when the arms are fixed.

Even if it was granted that movements of the arms created a slight pull which elevated the ribs, the amount could only be negligible, in view of the other detrimental factors to breathing pointed out in my article which occur when the arms are moved. The arms should not be moved during breathing exercises.—I am, etc.,

Portsmouth, March 22nd. HORACE HILL, M.R.C.P.

Obituary.

LOUIS HEMINGTON PEGLER, M.D.ED., M.R.C.S.ENG.,

Consulting Surgeon, Metropolitan Ear, Nose, and Throat Hospital.

THE death of Mr. Louis Hemington Pegler on February 26th, in his seventy-fifth year, has removed one who had held a leading place among otologists and laryngologists.

Mr. Pegler received his medical education at University College, London, and Edinburgh. He graduated M.B., C.M.Ed. in 1878, obtained the diploma M.R.C.S.Eng. in the following year, and proceeded M.D. in 1885. After ten years' service as surgeon to the Clay Cross Colliery Company at Alfreton, he came to London in 1892 to study otology and laryngology. He held the posts of registrar and pathologist to the Central London Throat, Nose, and Ear Hospital from 1893 to 1895, and in 1896 became surgeon to the Metropolitan Ear, Nose, and Throat Hospital, remaining on its staff until 1921, and contributing greatly to its progress. He was honorary consulting laryngologist and otologist to the London College of Music and several other institutions. During the war he acted as surgeon in charge of the ear and throat department of the Mile End Military Hospital. He joined the Laryngological Society of London in 1893, and was later a member of its council. He was secretary of the British Laryngological and Otological Association for three years, and took a prominent part in organizing its international meeting in 1895. He was a Fellow of the Royal Society of Medicine, and had been vice-president of its Laryngological Section. Mr. Pegler was actively concerned in the organization of the Laryngological Section of the International Medical Congress in London in 1913; he was a member of its council and curator of the laryngological museum in connexion with it. Ill health compelled him to retire from practice in 1921, and obliged him to decline the presidency of the Laryngological and Otological Section of the Annual Meeting of the British Medical Association, which he was offered in that year.

He published in 1900 a short monograph on nasal obstruction, and among his other contributions to literature were an article on the pathology of treatment of discrete angioma of the nasal septum, and the elaborate "Map scheme of the trigeminal nerve and its connexions," in which he defined its exact ramifications and anastomoses; this was published in 1913.

He was a great lover of classical music, being particularly interested in the works of Beethoven and Bach. He was also an enthusiastic naturalist, giving attention to botany, geology, and archaeology, and possessing an expert knowledge of mosses and flint instruments. His collections are preserved in the Natural History Museum and the South London Institute. He is survived by his widow, a daughter of the late Mr. Francis Palmer of Bedford.

JAMES LUKE, M.B., C.M.ED.,

Surgeon, Northern Infirmary, Inverness.

THE death took place at Inverness, on March 24th, o Dr. James Luke, after five days' illness from pneumonia Dr. Luke was born in Fifeshire, and studied medicine a the University of Edinburgh. During his undergraduat days he was a well known athlete, being noted as a boxer and being captain of the University Cycling Club at a time when cycle racing was a widely practised form of sport He graduated M.B., C.M. at Edinburgh in 1889.

Immediately after graduation, he acted as house-surgeon to the late Professor Annandale, and afterwards proceeded to Glasgow, where he was house-surgeon to Sir William Macewen. Subsequently he was appointed to the surgical staff of the Royal Hospital for Sick Children in Glasgow, and became an assistant surgeon in the Glasgow Royal Infirmary, where he was attached to the wards of Mr. J. Hogarth Pringle. During the South African war he served with the 2nd Scottish National Red Cross Hospital, which was organized largely from Glasgow, and on his return to this country he was one of those who received the freedom of Glasgow for their services. In 1907 he

went to Inverness, where he built up a large practice, working particularly as a surgical specialist. At the same time he was appointed one of the visiting surgeons at the Northern Infirmary, Inverness, which he served for twenty years, and where he gained a reputation as one of the chief surgeons in the North of Scotland.

Dr. Luke in his spare time was a noted sportsman, being regarded as a first-class shot, and he was also a keen angler in many of the rivers of the North of Scotland. He is survived by a widow, two sons, and two daughters.

THE LATE DR. JOHN BROWNLEE.

DR. A. FREELAND FERGUS (Glasgow) writes: With reference to your very appreciative and excellent article on the late Dr. John Brownlee, contained on page 598 of your issue of March 26th, I have to say that Dr. Brownlee had conferred upon him not the Fellowship of the Royal Faculty of Physicians and Surgeons, but the Honorary Fellowship, an honour very seldom bestowed by the Faculty. At the time of its being conferred I happened to be the president, and therefore I have taken the liberty of communicating this information to your readers.

Dr. ARTHUR GODFREY WILKINS, who died on March 9th, at the age of 50, was the second son of Professor A. S. Wilkins of Victoria University, Manchester, and received his medical education at Owens College, Manchester, and Dublin. He graduated M.B., Ch.B.Vict., with honours, in 1900. After serving as house-surgeon to the late Mr. F. A. Southam, at the Manchester Royal Infirmary, he became senior resident medical officer at the Salford Union Infirmary, from which he went to Manchester as resident medical officer of the St. Mary's Hospital for Women and Children. He then began to practise at Patterdale, on the shores of Ullswater, which involved long daily journeys of more than forty miles. On one of these he was accompanied by the late Sir Robert Morant, who thus obtained an insight into the question of mileage for country doctors. During his twelve years in Patterdale Dr. Wilkins was appointed justice of the peace for Westmorland. At the outbreak of war he disposed of his practice and, after spending some time with the French, received a commission in the R.A.M.C., serving in France and in German East Africa. In 1918 he was appointed a bimbashi in the Egyptian Army, but did not go to Egypt, as the war ended immediately after his appointment. On leaving the army he became chief school medical inspector for the Staffordshire County Council, and was responsible for the establishment of over thirty school clinics and infant welfare centres within eighteen months. Into this work he threw an immense amount of energy and enthusiasm. He subsequently spent two years as a ship surgeon, visiting China and the East Indies, and held the posts temporarily of superintendent of the Staffordshire Infirmary at Prestwood and of the Cheshire Joint Sanatorium at Market Drayton. His last appointment was that of medical superintendent of the Essex County Sanatorium, from which ill health compelled his resignation after about one year's service. Dr. Wilkins was a representative of the Mid-Staffordshire Division in 1921, and a member of the executive committee of the North Staffordshire Division 1923-24. A colleague, to whom we are indebted for the particulars given above, writes: Of fine physique, absolutely unassuming, and of great charm of manner, all classes of persons within ten minutes would be talking to Dr. Wilkins as if they had known him all their lives. He was one to whose kindness and common sense many appealed in times of trouble, and remembered his help with sincere gratitude.

Dr. CHARLES DRUMMOND MUSPRATT of Bournemouth, who died suddenly on March 10th, was born in India in 1859, the son of Mr. Henry Muspratt, I.C.S. He received his medical education at Guy's Hospital Medical School, took the diplomas of M.R.C.S.Eng. in 1884 and F.R.C.S. in 1885, graduated M.B., B.S.Lond. with honours in 1886, and became M.D. in 1889. After serving as house-surgeon at Guy's Hospital and assistant medical superintendent at St. Saviour's Union Infirmary he removed to Bournemouth for health reasons in 1891, and entered into partnership with Dr. J. Douglas. In 1892 he was appointed to the honorary medical staff of the Royal Victoria and West Hants Hospital, and in 1906 was appointed consulting surgeon. In 1919 he had a breakdown in health, which necessitated his retirement in the following year. For many years he was an active member of the British Medical Association, and was president of the Dorset and West Hants Branch in 1916. He was a member of the Ethical Committee of the Bournemouth Division from 1917 to 1923, and chairman of the Division during part of 1923. In 1892 he married the daughter of the Right Hon. Sir H. Knox; she died six years later, leaving three sons, one of whom was killed while serving in France in May, 1918, and another, who had won distinction in the Air Force by bringing down single-handed ten enemy aeroplanes, died through a crash at Martlesham, in March, 1918. Both the sons had been awarded the Military Cross. Dr. Muspratt himself rendered valuable assistance for two months during the war at the Allies' Hospital for French Soldiers at Yvetot near Rouen.

Dr. LEONARD SATCHWELL SMITH, who was killed in Nanking during the disorder consequent upon its capture by the Southern Chinese army, received his medical education at Birmingham and Newcastle-on-Tyne; he graduated M.B., B.S.Durh. in 1900. After holding the post of resident house-surgeon at the Queen's Hospital, Birmingham, he practised for some time in Kobe, Japan, and then moved to Nanking sixteen years ago as medical officer of the Tientsin-Pukow Railway. He also engaged in private practice in Nanking, and was very popular among the Chinese. In 1912 he married Miss May Williams, who with other refugees has reached Shanghai safely.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Fellowship Election at University College.

ARTHUR DUNCAN GARDNER, M.A., M.D., University College, F.R.C.S., has been elected to a special supernumerary Fellowship at University College. Dr. Gardner, who was elected to the Radcliffe Travelling Fellowship in 1914 and was awarded the Radcliffe Prize in 1923, is engaged in research in the Department of Pathology and is bacteriologist-in-charge of the Standards Department under the Medical Research Council.

Radcliffe Travelling Fellowship.

The Electors have notified to the Master and Fellows of University College the election, on March 7th, of Thomas Cecil Hunt, M.A., B.M., of Magdalen College, to a Fellowship on the foundation of Dr. John Radcliffe. Mr. Hunt was an open scholar at Magdalen College, who obtained the Theodore Williams Scholarship in Human Anatomy in 1922, the Theodore Williams Scholarship in Pathology in 1924, and the Radcliffe Scholarship in Pharmacology in 1924.

Radcliffe Prize.

Bernard Warren Williams, M.A., B.M., Exeter College, F.R.C.S., has, on the report of the examiners, been elected by the Master and Fellows of University College to the Radcliffe Prize for a thesis entitled "The importance of toxaemia due to anaerobic organisms in intestinal obstruction and peritonitis."

UNIVERSITY OF LONDON.

MR. W. E. LE GROS CLARK, F.R.C.S., has been appointed, as from September 1st, 1927, to the university chair of anatomy tenable at St. Bartholomew's Hospital Medical College, where he has been university reader in anatomy since the beginning of 1924.

Dr. Hamilton Hartridge, F.R.S., has been appointed, as from September 1st, 1927, to the university chair of physiology tenable at St. Bartholomew's Hospital Medical College. He holds the M.A., M.D., and Sc.D. degrees of the University of Cambridge, is a Fellow of King's, and, since 1919, has been lecturer on organs of special sense and senior demonstrator in physiology at the Cambridge physiology laboratories.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—*Part I*: *R. K. Bowes, Gladys A. Coventry, J. H. St.B. Crosby, A. Dala, H. R. Dugdale, R. A. Furniss, K. Jhaveri, E. W. Jones, Mary G. Jones, T. Lotter, Hilda M. C. MacMahon-Garry, J. S. Mather, G. W. Molyneux, Elizabeth B. Robson, J. L. A. Webster, F. J. Welton. *Part II*: I. Lipschitz.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—V. Friedland, R. W. Gemmell, T. Harrison, Agnes B. MacGregor, A. M. Robertson.

* With distinction.

UNIVERSITY OF ABERDEEN.

AT the graduation ceremony on March 23rd the following degrees and diplomas were conferred:

LL.D. (*honoris causâ*).—Matthew Hay, M.D., LL.D., professor of forensic medicine in the University of Aberdeen, 1883 to 1926; medical officer of health for the city of Aberdeen, 1888 to 1923.

Sir Frederick Gowland Hopkins, M.A., D.Sc., F.R.C.P., F.R.S.; Sir William Dunn professor of biochemistry in the University of Cambridge.

Sir William Milligan, M.D., C.M.; lecturer on diseases of ear and throat, Manchester University, and consulting aurist and laryngologist, Manchester Royal Infirmary.

D.Sc.—Lieut.-Col. Andrew Gray McKendrick, M.B., Ch.B., F.R.C.P.Ed.

M.D.—*Philip Bayer (commended for thesis).

M.B., B.Ch.—*W. Marshall, *A. S. Paterson, G. J. Allan, A. W. Barlenoch, J. Barclay, Catherine I. A. Craig, J. G. H. Davidson, R. G. Dingwall, P. T. J. Doss, A. D. Duff, G. A. P. Fraser, J. M. C. Gill, J. Leiper, J. W. Lobban, †N. J. Logie, †H. G. McPherson, C. P. Mann, N. G. Marr, J. R. Moir, J. H. Otty, Mary Riddoch, C. C. Ross, C. G. Walker, L. G. Walters.

D.P.H.—Jessie R. G. Dingwall, J. Innes.

* With second-class honours.
† Completed final medical examination with distinction.

UNIVERSITY OF GLASGOW.

THE University proposes to confer at the June graduation the honorary degree of LL.D. upon Sir Charles Ballance, K.C.M.G., C.B., consulting surgeon to St. Thomas's Hospital, London, and to the National Hospital, Queen Square.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—J. de Rosa, J. A. Fernandez, R. Kahn, A. M. A. Moore, R. C. Pratt, S. Slotar, W. G. H. Warner.

MEDICINE.—G. W. Ayres.

FORENSIC MEDICINE.—G. W. Ayres, A. C. F. Barrow, L. J. Lawrie, G. C. Rhys Jones, H. N. Walker.

MIDWIFERY.—A. C. F. Barrow, W. H. Collins, L. J. Corbett, S. Goldman, H. H. Lakin, W. D. Neill, S. le R. Switzer.

The diploma of the Society has been granted to Messrs. G. W. Ayres, A. C. F. Barrow, J. de Rosa, R. Khan, and H. N. Walker.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

AT the meeting of the Parliamentary Medical Committee on March 23rd, Dr. Fremantle presiding, Dr. Roche, an Australian practitioner who had worked with M. Spahlinger at Geneva, gave particulars of cases he had seen under the Spahlinger treatment for tuberculosis. His account of the results was very disappointing, though he would not say that no benefit had been done, and he cast no reflections on M. Spahlinger's personal sincerity. Dr. Roche's evidence conflicted with that of those members of the Parliamentary Medical Committee who had visited M. Spahlinger last year, and his statement was followed by a brisk discussion. During this Dr. Watts and Dr. Vernon Davies declared that they held to the opinions they had formed when they visited M. Spahlinger, and that if they were to be attacked themselves by tuberculosis they would go to him for treatment.

The Medical Committee decided that the urgency for an open lecture to members of Parliament on vaccination and small-pox had disappeared now that Dr. Watts no longer had a good chance to raise the question of vaccination when the House of Commons went into committee on the Civil Service Estimates. The lecture, consequently, was postponed *sine die*, but the Medical Committee considered that in view of recent public discussion on vivisection and the British Medical Association conference to be held on the subject on April 4th, it was desirable to invite all members of Parliament to a lecture on experiments on animals after Easter. Lord Dawson of Penn attended this meeting of the Medical Committee, and it is hoped that he will arrange to deliver the suggested lecture to members of Parliament early in May.

The medical profession has, unfortunately, lost the services of Dr. Haden Guest in the House of Commons. He was elected in the Labour interest for North Southwark in 1923, but, finding himself in disagreement with the policy of that party in respect of events in China, he resigned his seat and was not successful in the by-election, when the constituency was carried by a member of the Liberal party.

At a meeting of the Unionist Associations of the four Scottish Universities, on March 28th, Mr. John Buchan was chosen as a candidate for the vacancy in the parliamentary representation of those universities caused by the death of Sir Henry Craik. Mr. Buchan has accepted the invitation to stand "as a loyal follower of Mr. Baldwin, and believing his creed of voluntary evolution offers the best help for the country."

The House of Commons this week passed the Consolidated Fund Bill, agreed to the Lords amendments on the Poor Law Emergency Provisions (Scotland) Bill, and took the Committee stage of the Army and Air Force Annual Bill. During discussion on the last measure debate arose on the retention of the death penalty in the army for desertion and cowardice in the field. The Nursing Homes Bill, introduced by Mrs. Philipson, was down as second order of the day for April 1st. Debates also arose on the supersession of the elected guardians at Chester-le-Street, and on the encouragement of rural craftsmanship.

Physically and Mentally Defective Children.

When the second reading of the Consolidated Fund Bill opened, on March 24th, Mr. Trevelyan, on behalf of the Labour party, began a debate on education. He complained that when the Minister of Health revised the code of regulations governing elementary schools he had swept away all detailed building regulations, all special requirements as to floor space, playground space, and lavatory accommodation, and had left local authorities to build as they pleased. There were 623 schools which had been absolutely condemned, but not replaced, and 160,000 children in them. Mr. Morrison called attention to the provision made for educating subnormal children. In the case of blind or partially blind children, 2,408 out of 4,694 who in the opinion of the Board of Education might benefit from admission to special schools were either in public elementary schools or attending no school at all. Out of 4,154 totally deaf children in England and Wales, 319 attended ordinary schools. Of 2,170 partially deaf children, 1,632 were in ordinary schools, and 80 not in any school. The Board of Education showed 142,889 physically defective children, including cripples, those suffering from tuberculosis, and those requiring open-air schools. Of them, 94,332 were in public elementary schools, and 18,931 not in any school. Out of 33,000 mentally defective children, 12,470 were attending elementary schools who should not be there. There were 3,872 who were educable, but attending no school, and 110 education authorities had made no provision for teaching mentally deficient children. The Minister of Health had issued a circular saying: "It would not seem prudent to incur heavy expenditure at the present moment on new schools for such children or on enlargements of such schools." Yet the records of the existing schools showed that between 60 and 70 per cent. of the children who passed through these schools were at work two years after leaving them. In England and Wales on March 31st, 1926, accommodation was only provided for 17,154 educable mentally deficient children—about half the accommodation required. A committee on the education of mentally defective children had been sitting for two and a half years. It must be near the end of its labours. Why had the Minister intervened to advise against the construction of special schools? It was nonsense to suggest that the situation could be met by increased zeal on the part of the school medical services in ascertaining children with these disabilities. Lord Eustace Percy intervened to say that what he had declared in a circular was: "It will be understood that the Board do not underrate the value of special schools, but . . . the completion of the school medical service would appear to be of primary importance." Mr. Morrison retorted that the doctor, so far as mentally defective children were concerned, could never do the work of the teacher.

Replying to the debate, Lord Eustace Percy said the explanation of the number of blind children not attending special schools was either the unwillingness of the parents to have their children placed in such schools or the fact that the children had reached an age where the obligation to attend such schools no longer held good. In London there were a large number of physically or mentally defective children whom they could easily classify and bring together into special schools. But the main problem was in the areas where there were only a few defective children, who could only be dealt with by having a class somewhere in connexion with an elementary school, or by sending them to a residential institution. Members who had been to mentally defective schools in parts of the country other than London, and had seen the mixture in one room of widely differing grades and types of mental defectives, must have asked whether it was good for these children to be altogether. Were the Board to use its powers of compulsion with regard to mentally defective children, and dealt with them wrongly, that would be worse than not dealing with them at all. The Board was now for the first time about to present the country with the settled programmes of local authorities, and on these programmes arose the question whether a number of new schools for the mentally defective were to be built. From the beginning of last May the whole work of school building and of placing contracts for school buildings had been seriously affected by industrial disputes. Mr. Morgan Jones referred to the death rate of children under 5, and said some provision should be made to bring children at 4 or 5 into some form of nursery school where their physique as well as their moral training might be looked after. Dr. Menzies, the medical officer of the London County Council, had reported 10,000 children who were or had been suffering from rheumatic symptoms. Having regard to the effects in later life of this disease, there was a strong case for intensifying the medical service attached to educational work throughout the country. The Duchess of Atholl said everyone who had read the last report of the Board's principal medical officer must feel grave concern at the figures there given on the health of children under 5. Nursery schools were doing splendid work in improving the health of small children. Children suffering from heart trouble caused by rheumatic infection were to an increasing extent being admitted to schools for the physically defective. In some areas, thanks to the provision of orthopaedic treatment for the crippled child, increasing space was being found for rheumatic children or for

children who had affected hearts in schools originally intended for crippled children.

The Duchess of Atholl, on March 28th, informed Mr. Harris that the committee on the education of mentally defective children included among its members a Commissioner of the Board of Control, as well as other persons with special knowledge and experience of the subject. The committee had not decided whether to invite evidence.

The Scottish Midwives and Maternity Homes Bill.

A Standing Committee of the House of Commons commenced on March 29th to consider the Midwives and Maternity Homes (Scotland) Bill. Mr. Maxton moved that the section forbidding an uncertified woman to attend women in childbirth should be limited by the phrase "habitually or for gain." He suggested that if this proviso were not inserted any woman who went to aid a neighbour in childbed in the middle of the night when a doctor or nurse could not arrive for an hour or two might be convicted of an offence. Dr. Vernon Davies said such a woman would be completely covered by the provision exempting attendance in sudden or urgent necessity. Dr. Drummond Shiels, after referring to the high rate of maternal mortality in Scotland, suggested that Mr. Maxton's apprehensions would be met by a later amendment. Dr. Fremantle, as one who had administered the old Act in England for a dozen years, said that to prove "habitual" attendance a series of cases had to be adduced, and such a series meant an immense tale of suffering to mothers. In the past it had been almost impossible to get the immense mass of evidence required for the conviction of uncertified women who were practising. Mr. William Adamson said that unless the point made by Mr. Maxton was met an injustice would be done. The proposal of the bill reversed the criminal procedure in Scotland. Dr. Elliot said a point had been brought out in which the majority of the Committee felt that something should be done, and he thought that Mr. Barclay Harvey, who had introduced the bill, should assent to some concession. The position of those attending women in labour had always been specially restricted both in the law of Scotland and in that of other countries. To engage in medical practice without a qualification was not illegal, but to engage irregularly in midwifery was illegal. Mr. Westwood, a Labour member who had backed the bill, said it was not intended as a party measure. Mr. Barclay Harvey said he was ready to accept a further amendment in the name of Dr. Shiels which exempted the unqualified woman if "reasonable efforts were made to obtain the services of a person certified under this Act." Mr. Maxton said that all the untrained midwives who had been in the habit of maltreating the poor women of Scotland were now on the register. Dr. Shiels's amendment did nothing to meet the difficulty. The real trouble was poverty. Mr. Maxton's amendment was defeated by 26 to 12.

Dr. Drummond Shiels then moved his amendment. He said that in many areas in Scotland qualified persons were not available, even although a certain amount of medical assistance was provided by the Highlands and Islands Fund. The purpose of the bill was to see that every woman, however poor, received expert attention in childbed. As Mr. Maxton had said, there was a problem of poverty, but it was possible for any woman, however poor, to get qualified assistance without fees. No doctor, no nurse, no midwife could institute a prosecution under the bill. That would have to be initiated by a public official, the Procurator Fiscal. Mr. Barclay Harvey said there was no reason why Dr. Shiels's amendment should not be accepted. He suggested that it should be altered to read "or that reasonable efforts were made to obtain the services of a duly qualified medical practitioner or of a person certified under this Act." Dr. Shiels agreed, and the amendment was carried.

Mr. Maxton then objected to the proviso in the bill exempting medical students from the provisions against unqualified attendance. Dr. Elliot said that medical students might be a jesting race, but when they went to deal with a matter of life and death they did so with the fullest sense of responsibility. The bill provided that the whole weight of the General Medical Council would regulate the attendance of students in training on these cases. In the earlier cases the student would go with a trained practitioner. Later he would be on the telephone. Dr. Elliot remarked that his experience was that the student was too much disposed to call up his advisers in such cases. Mr. Westwood suggested that the proviso regarding students should be amended by adding "under the supervision of a properly qualified medical practitioner or midwife."

The Chairman, Sir Cyril Cobb, said that it was too late to put an amendment. Dr. Davies said the medical student had to do a minimum of twenty cases. Only towards the end of his course was he allowed to attend normal cases accompanied only by a nurse. If any abnormality occurred he had to report to the hospital at once. The student got his training gradually and the interests of the mothers were safeguarded. Mr. Adamson said an unqualified student was as great a danger as an unqualified woman unless under direct supervision. The Labour party would take the opportunity of the Report stage to deal further with this matter. Mr. Barclay Harvey said it would be wrong to take the responsibility off the General Medical Council and the Central Midwives Board. Dr. Elliot said there came a time in medical training when the trainee must feel the responsibility upon his shoulders. The student taking his twentieth case was as competent as the newly qualified practitioner taking his twenty-first. The clause was added to the bill. On the clause providing for compensation to midwives suspended to prevent the spread of infection, Dr. Davies moved to omit the proviso "if not herself in default." Dr. Elliot resisted the amendment, which was not pressed.

On Part II of the bill, dealing with the registration and inspection of maternity homes in Scotland, Dr. Drummond Shiels moved an amendment providing that sanitation be added as one of the grounds on which the local authority might refuse to approve premises for use as a maternity home. This was accepted. Dr. Elliot moved to provide that applicants should not be registered if "in the case of a maternity home which was not in existence at the commencement of this Act, the person having the superintendence of the nursing of the patients in a home is not either a qualified nurse or a certified midwife." This was also accepted. Further drafting amendments were made. Dr. Davies moved that for inspection purposes patients might be designated by numbers or initials. The chairman said that Mr. Barclay Harvey had a later amendment which provided that the records should only be open to inspection by qualified medical men. Dr. Davies agreed to await this amendment. Dr. Elliot moved to insert an amendment providing that records should be kept "in the case of each maternity home relating to (1) the persons engaged or employed at the home in attending on the patients or infant children; and (2) the patients admitted to the home; and (3) the infant children in the home." He emphasized the phrase "relating to." Widely drawn regulations would be made by the Scottish Board of Health, and would be laid on the table of the House. The Committee agreed to the amendment, and also to Mr. Barclay Harvey's amendment restricting inspection to officers who were medical practitioners.

Dr. Vernon Davies pointed out that the bill would enable local authorities to exempt institutions which were refuges for girls, and where confinements occasionally occurred, as well as hospitals. Dr. Shiels thought that there should be no exemptions. Mr. Barclay Harvey was willing to accept an amendment from Dr. Davies making the exemption run "any hospital or similar institution not carried on for profit and not used mainly as a maternity home." The amendment was accepted. Dr. Shiels moved that all such exemptions should be reconsidered annually by the local authority. Dr. Davies supported. An amendment for a similar purpose was moved by Mr. Barclay Harvey and accepted, Dr. Shiels's being withdrawn. Dr. Elliot moved a new definition, which ran: "'Qualified nurse' means a person registered in the general part of the register of nurses required to be kept under the Nurses Registration (Scotland) Act, 1919, or a person who had, before the commencement of this Act, completed a three years' course of training in a hospital which was during the period of her training or subsequently became a training school approved by the General Nursing Council for Scotland, or the General Nursing Council for England and Wales, or the General Nursing Council for Northern Ireland for the purpose of admission to the general part of the said register."

Dr. Elliot said that nurses registered in England could be added to the Scottish register by a simple arrangement. The section was added to the bill, and the bill was reported to the House.

Scottish Administration.

On March 23rd Sir John Gilmour moved the Reorganization of Offices (Scotland) Bill. He said that in the past the administration of Scotland had been conducted by a system of boards. The bill was to set up in its place a system of departments on the lines of the great departments which existed in England, such as the Ministry of Health. Under the existing system the Board of Health in Edinburgh had a number of advisory committees composed of unpaid outside people skilled in certain interests which came before the Board. Nothing in the bill would lessen the necessity or the opportunity for continuing such boards. Mr. William Adamson moved the rejection of the bill.

The debate was adjourned.

Alcohol and Flying Accidents.

Captain Garro-Jones asked the Prime Minister, on March 23rd, whether he had inquired into the rules governing consumption of alcoholic drink by flying officers, engineer officers, and mechanics during flying hours, and whether he had received any complaints of overwork by flying officers. Captain Garro-Jones explained that he made no charge of excessive drinking. Mr. Baldwin replied that as a suggestion had been made that the consumption of alcohol had some bearing on recent accidents he had made careful inquiries and had satisfied himself that the consumption of alcohol among Royal Air Force personnel in general, and officers in particular, was very small. He had also satisfied himself that there was no evidence that consumption of alcohol had caused or contributed to any accidents, and none that overwork by flying officers had been the cause [illegible] in Garro-Jones insisted that in some cases [illegible] iquor had been consumed immediately befo [illegible] ientific opinion held this to be a contribu [illegible] The Speaker observed that these were r[illegible]

In the House of Lords, on March 23rd, Lord Gorell called attention to the frequency of accidents in the Royal Air Force, and asked why aeroplanes were not fitted with gear to give the pilot warning when stalling was about to occur, and whether the Government was adopting any device to prevent petrol tanks from bursting into flames. The Duke of Sutherland, replying for the Government, said continual efforts were being made to reduce the number of accidents. Pilots were constantly under supervision by senior officers and the Royal Air Force Medical Service. The medical service was alive to the necessity of detecting any incipient physical unfitness, strain, or staleness before harm could be done. Training was progressive and not hurried, and pilots had on an average 100 hours' flying experience before they were posted to squadrons. In no single case had indulgence in alcohol been proved to have caused or contributed to an accident in all the years covered by the official statistics. The average wine bill of pupil officers at the training schools was well under £1 a month.

and that of squadron officers little in excess of the same figure. The anti-stalling gear had been found suitable only for some types of aeroplane. The department was making every effort to find a petrol tank which would give adequate security both in accidents and enemy action. A general policy had been adopted that all personnel in the air should carry parachutes. But only in collision, fire in the air, or aircraft failure at a height could the parachute be instrumental in saving life.

Detection of Tubercle in Milk.—Sir G. Hennessy, replying to Mr. Everard on March 29th, said that various investigations had been promoted during the past few years in the attempt to devise better methods for determining whether milk was tuberculous. One of these, undertaken jointly by workers at the National Institute for Medical Research and at the National Institute for Research in Dairying, made possible a considerable improvement of pre-existing methods. An account of this was published in 1925. Further search would be made for new means of attacking this difficult problem. The reference given by Sir G. Hennessy was as follows: S. R. Douglas and L. J. Meanwell, "A new method for the concentration of bacilli in tuberculous milk" (*British Journal of Experimental Pathology*, 1925, vol. 6, p. 203).

Tuberculosis Treatment.—In reply to Colonel Day, Mr. Chamberlain said the total expenditure in England and Wales on the carrying out of the approved schemes for the treatment of tuberculosis during the last three completed financial years, excluding capital expenditure, was as follows: For the year ended March 31st, 1924, £2,884,062; 1925, £3,034,600; 1926 (provisional figures), £3,157,879.

Light Treatment.—Sir Kingsley Wood, on March 28th, told Mr. Cadogan that the Minister of Health had no authority to make regulations whereby only qualified medical practitioners should be allowed to treat patients with the ultra-violet ray. In cases in which his approval was required to the installation of artificial light apparatus, it was made a condition of approval that the treatment would be given under the supervision of medical practitioners who had experience of this form of treatment. The Minister of Health was informed that a central clinic and training centre where doctors and nurses could be instructed in the use of actinotherapy in the treatment of disease, had been established in London. Mr. Cadogan asked whether actinotherapy could not be placed in the same category as dangerous drugs. Sir K. Wood replied that if a question were put down he would consider it.

Indian Medical Service.—On March 28th Earl Winterton informed Mr. Pethick-Lawrence that the Secretary for India had found it necessary to consult the Government of India further on the question of providing facilities for study leave to Indian officers who entered the Indian Medical Service by competitive examination in London. He hoped that an announcement could be made very soon. In the House of Lords, on March 29th, Lord Lamington asked the Secretary for India what steps were being taken to reconstruct the Indian Medical Service and to provide adequately for the medical needs of the people of India. The Earl of Birkenhead said that he had been in correspondence with the Government of India, which consulted the provincial governments with a view to the future organization of the medical service in that country. He had recently received from the Government of India its final proposals, and his comments on these were forwarded on February 17th. Pending receipt of a reply he was not in a position to give full details of the scheme which it was proposed to adopt. The cardinal features of it were: (1) the retention of the Indian Medical Service and the necessary war reserve of trained medical men; (2) the provision of European medical attendance for European officers of the Superior Civil Service and their families; (3) the creation of provincial medical services, recruitments for which would be carried out by the local Governments. He anticipated that it would be possible to bring the new scheme into operation at no distant date.

Disablement Pensions.—The Minister of Pensions states that 26,200 disablement pensions ceased in 1924, 16,150 in 1925, and 13,150 in 1926. Cases of a wound or sickness breaking out again after a disability pension has been stopped and the statutory year allowed for appeal has passed are comparatively rare and are met by provision of medical or surgical treatment in the course of which the Ministry can judge whether special action is required. Answering Sir Richard Barnett, Major Tryon said he could not give a free choice to the pensioner between metal and wooden artificial limbs, or in any other type of appliance. When the medical officer of the Ministry considered that a metal limb should be given it was issued. The statement that the Ministry was providing wooden stumps was untrue.

Palestine: Quarantine Station.—Mr. Amery, on March 28th, said that the High Commissioner for Palestine reported that there was now no mosquito breeding in the area within one and a half kilometres of the quarantine station at Haifa, and that no anopheline mosquitos had invaded the quarantine station from a swamp, which existed at that distance. Lord Plumer was advised that no more suitable and no healthier site than the present one could be found for the permanent quarantine station.

Sexual Offences and Young Offenders in Scotland.—On March 29th Sir J. Gilmour, replying to Mr. R. W. Smith, who asked if he proposed to introduce legislation dealing with the question of sexual offences against young persons in Scotland, said that he proposed to await the report of the Scottish Committee on Young Offenders now sitting, and to consider the two reports together. He had already taken action on recommendations of the committee which did not require legislation.

Notes in Brief.

On March 29th the Sale of Food and Drugs Bill, which has already passed through the Commons, was read the second time in the House of Lords.

The estimated daily cost of each occupied bed in an army hospital is 13s. 7d., of which 7s. 4d. is for staff and 2s. 6d. for patient's maintenance.

At the end of 1926 there were 99 licensed establishments for pasteurizing milk in England and Wales, and 591 other licensed establishments for the sale of such milk. For certified milk 120 producers' licences were current, for Grade A (tuberculin tested) 131, and for Grade A milk 258.

The Minister of Health does not propose to institute any inquiry into the physical, as opposed to chemical, methods of improving flour. He understands these methods are still experimental.

The Minister of Health has appointed a departmental committee to consider and to make recommendations on the Optical Practitioners (Registration) Bill, which is set down for second reading on May 13th.

Mr. Chamberlain is now considering a recommendation of the Royal Commission on National Health Insurance that the ordinary benefits of health insurance should be provided on a basis of mutual insurance to deposit contributors who, through the state of their health, cannot obtain admission to an approved society.

Commander Kenworthy presented, on March 23rd, a petition, signed by 15,286 persons, praying that vivisection be prohibited by law.

Sir P. Cunliffe-Lister states that the regulations respecting the standard of accommodation for seamen on board ship have not been revised since October, 1923.

Medical News.

THE College of Physicians of Philadelphia has arranged to commemorate the hundredth anniversary of the birth of Lord Lister on the evening of April 6th. The president, Dr. Hobart Amory Hare, will take the chair, and addresses will be given by His Excellency Sir Esmé Howard, K.C.B., the British Ambassador, and Dr. Astley P. C. Ashhurst.

SIR WILLIAM DE COURCY WHEELER presided over the annual meeting and festival dinner, in London, of the Irish Medical Schools' and Graduates' Association on March 17th; about 150 members and guests were present. Colonel G. A. Moore proposed the health of "The Guests" in a witty speech, and replies were made by Vice-Admiral Sir Frederick Field, Sir Squire Sprigge, and Dr. Bertram Watson. The toast of "The Association" was proposed by Dr. Kenneth Fraser, and Sir William Wheeler responded. The arrangements for the evening, which worked out very successfully, were made by the honorary secretary for the dinner, Dr. F. R. Holmes Meyrick.

AT the invitation of Mr. Comyns Berkeley twenty-eight personal friends met Dr. Russell Andrews at the Garrick Club on March 22nd to say farewell to him on his retirement to the country. The company included Mr. J. Banister, Dr. J. Barris, Sir George Blacker, C.B.E., Dr. Bellingham Smith, Mr. Victor Bonney, Mr. A. Bourne, Dr. Darwall Smith, Mr. S. Dodd, Dr. M. Donaldson, Dr. T. W. Eden, Dr. J. Fairbairn, Dr. J. Hedley, Mr. Eardley Holland, Dr. V. Lack, Dr. S. G. Luker, Sir Ewen Maclean, Dr. A. Palmer, Mr. F. Provis, Mr. Carnac Rivett, Sir Henry Simson, K.C.V.O., Mr. T. Stevens, Mr. Clifford White, Dr. A. Willett, Dr. J. Wyatt, and Sir Hugh Rigby, K.C.V.O., and Dr. Lewis Smith, who joined the London Hospital in the same year as the guest of honour. Dr. Eden proposed in most fitting terms the health, long life, and happiness of Dr. Russell Andrews, which was drunk with the greatest enthusiasm, after which Dr. Russell Andrews replied.

SIR ERNEST HATCH, K.B.E., presiding over the annual meeting of University College Hospital last week, referred to the increasing popularity of the infan[illegible]. 100 clinics having been held during the [illegible] attendance of considerably over 5,000. Nearly 10,000 home visits had been paid by health visitors. The present accommodation was inadequate, and he suggested the conversion of a building at the back of the obstetrical hospital into a new infant welfare centre at the cost of £20,000. The number of in-patients in the hospital had increased by nearly 600 over the previous year.

THE Fellowship of Medicine has arranged to supply a comprehensive ticket for a general course of post-graduate work available at any of some fifty London hospitals for any period from one week to one year; the charges range from two to twenty guineas according to the period required, and the holder can thus plan a time-table in accordance with his special requirements. Owing to the Easter vacation the special courses arranged for April will not begin until the last week. The Royal Waterloo Hospital will provide a comprehensive course in medicine, surgery, and gynaecology. A series of eight lecture demonstrations on tropical medicine will be given on Tuesdays and Thursdays, at 2 p.m., at the

London School of Tropical Medicine, beginning April 27th. Dr. Heald will give a series of four lecture demonstrations on successive Wednesdays at the Royal Free Hospital, at 5.15 p.m., from April 27th. Copies of all syllabuses, the *Post-Graduate Medical Journal*, and the general course programme may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE course on infant care, for health visitors, nurses, midwives, superintendents of infant welfare centres, and others interested, will be held at the Infants Hospital, Westminster, from 6.30 to 7.30 p.m. on Mondays, from April 11th to June 27th. This course prepares for the post-graduate certificate of the National Association for the Prevention of Infant Mortality. The subjects include: breast-feeding; feeding of the toddler; common diseases of the skin in childhood; the early education and prevention of crippling; mental and subnormal children; the causes of ear, nose, and throat trouble in young children; diphtheria; sunlight treatment; summer diarrhoea; and the psychology of the toddler. Particulars may be obtained from the secretary of the association, Miss I. Colhoun, 117, Piccadilly, W.1.

THE Joint Tuberculosis Council has arranged a post-graduate course in tuberculosis in Copenhagen in May, under the supervision of Dr. Axel Reyn. The course will include the surgical treatment of pulmonary tuberculosis and the use of *pneumothorax, tuberculosis of the eye and larynx, and an* exposition of the Danish campaign against this disease. Members of the course will leave Harwich on May 7th and return there on May 21st; the approximate cost is estimated as £25. Further information may be obtained from the Honorary Secretary, Post-Graduate Courses, The Larches, Farnham Royal, Bucks.

AT the annual meeting of the Society for the Study of Inebriety (Alcoholism and Drug Addiction), to be held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Tuesday, April 12th, at 4 p.m., a discussion on the Inebriates Act of 1898 will be opened by Dr. R. W. Branthwaite, C.B., late Commissioner on the Board of Control.

THE eighth Salon des Médecine for the exhibition of pictures, engravings, sculpture, and decorative art by members of the medical, dental, and veterinary professions and their families will be held in Paris from April 3rd to 12th. The organizing secretary is Dr. Paul Rabier, 84, Rue Lecourbe, Paris XVe.

THE Astley Cooper studentship at Guy's Hospital falls vacant on July 4th. The present value of the prize is about £150 per annum, with an additional sum of £50 for expenses. Some particulars are given in our advertisement pages, and further information can be obtained from Mr. C. H. Fagge, M.S., Guy's Hospital, S.E.1, to whom applications for the post must be sent by May 31st.

THE Ancoats Hospital in Manchester was founded in 1828 and it is proposed to hold centenary celebrations in August next year. An appeal is about to be launched for funds to construct a new ward containing a hundred beds at a cost of £100,000. The hospital already treats 20,000 accident and casualty cases annually although only a hundred beds are available; two new operating theatres are also required. The hospital is situated in one of the most crowded parts of Manchester, and the demands made upon it are great. Recent additions include a new nurses' home and an extension of the out-patients' department.

DR. WILLIAM EVANS THOMAS of Ystrad-Rhondda has been appointed sheriff for Merionethshire.

ON his retirement from the post of medical officer of health for Canterbury after fifty years' service Dr. Frank Wacher has been presented with an inscribed silver cigar and cigarette cabinet by the officers of the corporation.

DR. RICHARD EAGER, medical superintendent of the Devon Mental Hospital, Exminster, has been presented by the officers and staff with a silver salver to commemorate his twenty-one years' service in that institution.

WE have received a copy of the two hundredth volume of the *Deutsche Zeitschrift für Chirurgie*, the well known German surgical journal which was founded in 1872 by Karl Hüter and Albert Lücke. The volume, which consists of 865 pages, contains a preface and an obituary notice by the editor, Professor F. Sauerbruch of Munich, of the orthopaedic surgeon, Professor Georg Perthes of Wurzburg, with his portrait, thirty-seven original articles by leading German, Austrian, Hungarian, Swedish, Spanish, Greek, Dutch, and Finnish surgeons, and an index for vols. 191–200 inclusive.

AN international congress on goitre will be held at Berne at the end of September.

THE Bureau of the Far East at Singapore reports that for the week ending February 26th there were 18 cases of plague with 12 deaths, 66 cases of cholera with 53 deaths, and 452 cases of small-pox with 150 deaths.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocre Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

HIGH ALTITUDES IN OLD AGE.

"M.B." asks: Is it advisable for a practitioner aged 74 to visit places of the altitude of Murren or Zermatt or to travel in the Dolomites? Quick ascent in a funicular railway has certainly caused some discomfort. Would the same thing apply to a more gradual ascent by rail or car?

*** We have referred this question to Dr. Leonard Hill, F.R.S., who has been good enough to reply as follows:

If a man's heart, blood vessels, and kidneys are in a healthy condition there is no reason why he should not go up to the Swiss resorts at altitudes of some 5,000 ft., even though he be 74 years old. If the rapid ascent in the funicular railway the whole way causes any discomfort let him break his journey half-way up for a night and so become acclimatized.

MORBID SHYNESS IN A CHILD.

DR. R. MACD. LADELL (Birmingham) writes in further answer to "K. H. G.": No psychological analysis is possible either with children or adults until the psychologist has ceased to be a "stranger." In this particular case it is probable that much preliminary time would have to be spent in getting on good terms with the child and in educating the parents, since their reactions to the child are probably faulty.

INCOME TAX.

Contributions to the Press.

"G. R. H." inquires whether a few occasional guineas earned by contributions to the press on (1) medical or (2) other subjects are liable to income tax.

*** We are of opinion that an isolated contribution might not be liable—though that is open to doubt—but it is clear that casual contributions extending over a period would create liability.

Depreciation of Motor Car.

"D." discussed the question of a depreciation allowance with the inspector of taxes about a year ago, who informed him that if he claimed "depreciation" no allowance would be made on the purchase of a new car and suggested that that claim be dropped. It has become probable that our correspondent will retire before he needs to renew his car, and consequently will never be in a position to claim renewal allowance, and he has therefore again raised the depreciation question. The inspector declines to allow any sum for years prior to 1927–8, but takes the annual depreciation into account as from the date of purchase of the car in computing the 1927–28 allowance. Is there any redress?

*** The depreciation is for the year of assessment, and it is an established principle that it must be calculated on the capital value as written down from the date of purchase. The inspector is therefore correct in putting the allowance at £49 for 1927–28. But we suggest that our correspondent has some prospect of success in pressing his claim to add to that sum the £68 and £58 referable to the years 1925–26 and 1926–27. It is true that where depreciation is allowed no claim for "cost of renewal" can hold good, but an "obsolescence" allowance is not excluded, and in this case would have been claimable if the car were replaced. The inspector was therefore not quite correct in saying that if

depreciation were claimed "no allowance could be made in the event of the purchase of a new car," and if our correspondent put it to him that his action in withdrawing his former claim was based on that advice, the inspector might—and we think probably would—agree to the resurrection of the old claim, or in the absence of such agreement it might be authorized by the Board of Inland Revenue.

LIFE ASSURANCE AND TUBERCULOSIS.

DR. ROBERT CARSWELL (Wandsworth, S.W.18) writes: Mr. Ferris-Scott (JOURNAL, March 19th, p. 552) appears to me to have mistaken the scope of my suggestion that holders of a negative tuberculin test certificate should be accorded specially favourable terms for sickness and life assurance. My suggestion is only concerned at this stage with the public recognition of the broad general proposition that, in the case of holders of such negative certificates, the diminished risk of the multifarious mass of disease due to the mischievous activities of the tubercle bacillus does, in point of fact, merit a diminished insurance premium. Were this proposition generally endorsed by members of the medical profession the insurance companies could be relied upon to work out the figures. As to the question of subsequent infec- [illegible], but individuals who were fortunate [illegible]uble and expense, a negative certifi- [illegible] knowledge of the subject, almost [illegible] guard against subsequent infection. [illegible] a simplified form in, say, five years could be carried out without much trouble or expense, and, as a further point, any such subsequent infection would be detected at an early stage, when it could be comparatively easily dealt with. The commercial value of a negative tuberculin test certificate is generally recognized and utilized in veterinary work. Why not in human? The chief objection seems to be the probably small number of successful candidates; nevertheless, the proposition might usefully be included in an insurance company's list of additional advantages. By so doing the insurance company would tend to foster the ideal of a tuberculosis-free community, and assist in tackling the question at the right end.

OLD MEDICAL BOOKS.

THERE have been up to now few really outstanding rare medical books in the auction sales of the present season; indeed, few old textbooks have come to the hammer at all until recently. Just at present, however, there are some interesting volumes to be found in the auction catalogues. There are, for instance, M. Andry's *Orthopædia; or the Art of Correcting and Preventing Deformities in Children, Translated from the French* (1743); Peter Lowe's *Discourse of the Whole Art of Surgery* (1634—not the first or even an early edition, of course); Christopher Bennet's *Theatri Tabidorum Vestibulum* (first edition, 1654—a treatise on consumption and other wasting diseases); Sir T. Elyot's *Castel of Helth* (1541); Edmund Gayton's *Hymnus de Febribus* (first edition, 1653); these will have been sold before this note is published. In the two following sales at Messrs. Sotheby's, next week and the week after, are a few books of great rarity. Thus Christopher Wirsung's *Praxis Medicinæ Universalis; or a General Practise of Physicke . . . now translated . . . by Jacob Moran* (1598) is one of the only two copies known. Oswald Gaebelkover's *Boock of Physicke . . . nuely translated out of Low Dutch into Englishe by A. M.* (Dort, Isaac Caen, 1599) is one of three copies known. Almost as rare, and much more interesting, is Thomas Willis's *Cerebri Anatomæ; cui accessit nervorum descriptio et usus* (first edition, 1664, with 5 plates of the nervous system after Sir Christopher Wren). Besides these may be mentioned also Robert Grove's *De Sanguinis Circuitu ab G. Harvaeo invento*, 1685; Walter Charleton's Harveian Oration for 1705; Nicholas Monardes on Eastern Medicine, Venice, 1575; Nicander's *Theriaca; ejusdem Alexipharmaca*, Venice (Aldine Press), 1523; Gideon Harvey (senior) on *Smallpox and Malignant Fevers, with an exact Discovery of the Scorvey*, 1685; Thomas Fuller's *Pharmacopœia Extemporanea*, 1709; John Brown's *Elementa Medicinae*, Edinburgh, 1784; and John Aitken's *Principles of Midwifery*, 1786.

THE DETERMINATION OF SEX.

DR. A. P. MURTZ (London, N.4) writes, with reference to the correspondence published in our issues of November 13th (p. 918) and December 18th, 1926 (p. 1205), as follows: I have touched upon this interesting problem in articles published in the *Medical Times*, August 5th, 1916, p. 465, and in the *Lancet*, September 1st, 1917, p. 368. I then mentioned, *inter alia*, that I would publish the result of my future clinical observations on the subject in due time. I stated then that there is no absolute reliance as to the time, pre- or post-menstrual, when male or female issue can be predicted, but judging by my own experience of observations on over 2,500 maternity cases, I think that, as a rule, pregnancies occurring immediately before menstruation produce females, and those within the first week after menstruation males. I have had the confidence of a great many married couples who had followed my advice as to time of coitus. When pregnancy occurs during the second and third week of the interval between the menses there is no probability of sex determination at all. Sex is determined at the mon [illegible] logical differentiation during ovum leads us to nothing for ce [illegible] that logical deductions based on biological knowledge are the only means at our command of establishing some feasible data. Vitality of the spermatozoa or ova, as the case may be, is the only essential in determining sex. The survival of the fittest in the struggle for existence comes here into play. In hermaphrodites of the lower animals, although male and female organs are present on the same creature, passive self-fertilization never occurs. Active copulation with a second individual *must* take place. Even here it is the struggle of [illegible] which determines the very existence o [illegible] —th [illegible] the [illegible] the ovum whi [illegible] congestion of the uterus precedes the menstrual flow exciting the ovaries to discharge their ova to meet the spermatozoa for fertilization, and, if conception happens, the latter occurs in the Fallopian tubes, *there to remain until ready to descend into the fundus* uteri. The menstrual flow does not then occur. At the time of the menses female activity is very great, probably surpassing that of the male—a female survives as the fittest. Coitus immediately after the flow, say within a week, if pregnancy ensues should produce a male. Ovulation may occur at any time during the menstrual interval, but it is less vigorous, and the product of conception should be a male. I can only speak of probabilities, but to me they are sufficiently convincing to advise my patients as to the times of sexual connexions. I have generally been satisfied with the result.

CHLORINATED DRINKING WATER AND PRESCRIBING AND DISPENSING.

DR. JAMES OLIVER (London, W.1) writes: I would like to draw attention to the fact that because it is to-day a common practice to chlorinate our drinking water by the use of chloride of lime and liquid chlorine that in prescribing and in dispensing in any mixture *sodium bicarbonate or potassium bicarbonate* the added water should be distilled. If the water specified or used is merely tap water, then slowly but surely insoluble carbonate of lime is thrown down and what happens to the soda or potassium it is impossible to say at present, as our knowledge of the chemical changes produced in conjunction with the carbonate of lime formation is scanty. Moreover, from a therapeutic point of view there is the question of the carbonate of lime present in the mixture to be considered. Possibly it may, when it enters the stomach, be converted into calcium chloride, or if the mixture containing the bicarbonate is taken by a patient suffering from gastric ulcer in any stage or degree the carbonate of lime may be harmful.

SIR JAMES CRICHTON-BROWNE'S ESSAYS.

MR. FRANK BELBEN, M.B., F.R.C.S. (Bournemouth), writes to recall the old adage, "Always verify your quotations." He is moved to do so by an error in a quotation from *Romeo and Juliet* (v, 3, 88) made in the course of a review last week of Sir James Crichton-Browne's essays. The lines in the *Globe* edition of Shakespeare are thus printed:

> "How oft when men are at the point of death
> Have they been merry! which their keepers call
> A lightning before death. . . ."

MEDICAL GOLF.

THE knock-out tournament of the Medical Golfing Society has now reached its semi-final stage. The following gentlemen are left in the competition: J. Cunning, E. N. Plummer, J. Everidge, and E. Playfair.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 107.

LISTER CENTENARY.
1827–1927.

THREE DISCOURSES

DELIVERED ON WEDNESDAY, APRIL 6TH, DURING THE LONDON CELEBRATIONS.

LISTER AS A PHYSIOLOGIST.

BY

SIR CHARLES S. SHERRINGTON, O.M., G.B.E., M.D., F.R.S.,

WAYNFLETE PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF OXFORD.

THE invitation has been extended to me to offer a few words about the contributions made by Lister to physiology. Lister's very earliest scientific papers were all physiological. Indeed, he may be said to have entered by way of physiology on his surgical researches, which were to achieve so much.

SMOOTH MUSCLE.

His first paper was on the "Contractile tissue of the iris." Work done with the microscope, which he used for the study of function rather than of form alone, it appeared in 1853 in the first number of the first volume of the now well known *Quarterly Journal of Microscopical Science*. Lister was then 25 years of age, and that his maiden voyage of discovery should employ the microscope was but natural in the son of Joseph Jackson Lister, that remarkable man, who, leaving school at the age of 14 for the business he conducted so successfully, had yet found time to cultivate optics to such purpose as to give the world the achromatic microscope. This, Lister's earliest paper, on the iris, supplied the first full and correct description of the radiating muscle dilating the pupil. It thus made a lasting mark upon its subject.

Lister's second paper, of a few months later, dealt likewise with involuntary muscle; this time in the skin, where Kölliker had recently discovered the arrector muscles of the hairs; this discovery Lister confirmed, and in several respects extended.

We may be struck by the remoteness of these, Lister's first themes, not only from surgery, but, indeed, from actual practice; they are academic. I think we have to picture him a young man to whom what really mattered was engagement on research, and less at that time what in particular the research might be: a young man so ardently curious about nature, especially animate nature, that he turned with enthusiasm to the problem that came first to hand. And these papers in the simplicity of their text recall something of the upbringing in Lister's Quaker home. There is already the sobriety of expression which, characteristic of Lister all his life, made yet the more impressive his own self-restrained statements of his great results later on. No man in his career had more excuse for, more justification for, hyperbole of phrase than had Lister, and no man ever indulged in hyperbole less than did he. It is therefore of significance when in these early papers the young author allows himself an expansive adjective, as for instance when he writes "the grand discovery of plain muscle-cells," "the beautiful muscle of the iris." We feel these expressions to be from him not mere phrases. An abiding interest of these papers is that they reveal points in Lister's so to say original nature; and among these are penetrative and faithful observation, a catholic enthusiasm for research, a restless testing of authority by observed fact, an unhesitating self-submission of opinion to whatever the truth might assert, the fear of nothing except missing the truth.

His third paper, still physiological and on the same theme, smooth muscle, followed some four years later. The cellular nature of that tissue had been denied; Lister returned to its further proof. He furnished it overwhelmingly. Forty years afterwards the then foremost authority on this tissue wrote of this paper of Lister's as being still not only abreast, but in several respects ahead, of other subsequent papers on its subject.

This work was Lister's farewell contribution to that particular theme. Much had by then happened and was happening to him to compel his main interest elsewhere; in short, his scientific enthusiasm had definitely orientated its search in the great field of the unknown. His spirit of inquiry had found a direction of compelling interest to it, a lodestar of overpowering attraction. In his own words, written to his father, he had fallen in love with surgery. And with that wide, though unified, field enchantedly before him, the genius within him pointed to the prime and all-pervading problem in that field as being, not this or that particular skill or operation, but the fundamental process and reaction of inflammation itself.

NERVOUS CONTROL OF ARTERIES.

Henceforward his physiological research became merely collateral to the pathological study engaging his main thought. Thus it was with his paper on the nervous control of arteries, distinguishing between the immediately local and the more distant effects of a stimulus, and especially of an irritant stimulus upon the blood vessels. The local effect, he concluded, was independent of the nervous system, but with a surrounding zone of effect mediated by nerve—a finding closely suggestive of present-day views. Another paper was that on the pigment cells of the frog's skin—those cells on which the animal's well known colour changes depend. Lister concluded the shift of pigment to be a shift of the pigment grains within the cells themselves, and the way in which he consolidated and marshalled his evidence for that is a striking instance of his thoroughness as an investigator. There is little doubt that from detailed study of these pigment cells Lister gained much

of that vivid and intimate conception of cell life struggling against irritant agents which directed his surgical strategy afterwards.

INHIBITORY ACTION OF VISCERAL NERVES.

Another of his physiological investigations concerned the inhibitory nature of certain visceral nerves. He wrote: "I have been led to make an experimental inquiry into this 'so-called inhibitory agency' because it appears to me to have an intimate bearing upon the question how inflammation is developed through the medium of the nervous system at a distance from an irritated part." His main conclusion was that inhibition resulted from more energetic action of those same nerves which when working mildly produce increased action.

Then, more closely related still to his pathological inquiries, followed two papers on clotting of blood, confirmatory, as he himself remarks, of his conclusions arrived at about inflammation. These papers and the year 1863 practically concluded the tale of Lister's researches devoted directly to physiology. Perhaps their main interest now is their revelation of their author in his earliest research career. Conspicuous in them is capacity for noting detail and the rarer power of sifting out from the detail its broader meanings. Another of their qualities is a voracious appetite for seeing for himself phenomena many would be content to take on trust from the excellent descriptions given by others. Lister was satisfied by nothing less than seeing for himself, and his eye never staled. Moreover, even at this stage, though he might appear engaged on diverse problems, he was in fact centred upon one problem, of which from his point of view the several were but several aspects. Thus, these early papers show that in reality quite early in his career he had not only found but had whole-heartedly flung himself upon what was to be his life-work and his life's problem—a problem we may almost subsume under the one broad term "*inflammation*." That was the study which he was to follow to a practical solution so magnificently, and in doing so exhibit what these earlier papers had less opportunity for showing—the splendid power of establishing, and systematically following through its consequences, a great generalization. Hence from these earlier researches we can see spring that triumphant career of experimentation and observation, in the laboratory and the ward, which, with a really surprising speed of mastery, winged Surgery for that which she is to-day—a far-flighted angel of healing the civilized world over.

ANTISEPTIC SURGERY IN PHYSIOLOGICAL EXPERIMENT.

But these papers whose features we have been examining far from exhaust the gift made by Lister to physiology. In addition to and beyond them he enriched it with the contribution of enhanced means towards its own most cherished aims. He put into the hands of physiology for all time a superlative refinement of its method, and made possible observations otherwise impossible. Sir Berkeley Moynihan has eloquently insisted on the importance of surgery as a means of discovery. In physiology, how could Pavloff have achieved his epoch-opening study of the digestive processes except by leaning upon Lister's surgical principles? Ferrier initiated his study of localization of cerebral function by means of Lister's surgical principles. How could the physiologists of Toronto, less than four years ago, have bestowed upon diabetic sufferers that merciful remedy insulin, had it not been for the legacy of operative principle and science bequeathed to them and to the whole world by Lister?

And Lister's own words leave us in no doubt as to what a source of rejoicing it was to him that among benefits accruing from his work was this one, an enhanced scope and power for physiology and experimental medicine. He dwelt both in public and in private upon the need and importance of such experimentation for the progress of knowledge necessary to civilization. He rejoiced that he had contributed to its power. And indeed the experimentalist owes to Lister an instrument of research whose beneficent future the boldest imagination may well halt to set limit to.

And of the gifts of Lister to humanity one which the experimentalist is with especial gratitude ever mindful of is that, while helping man to mastery over disease alike for animal and man, he contributed to free that necessary experimentation from the infliction of pain. Man, sacrificing animal life as he does to satisfy the material needs of humankind, has the right to regard the intellectual need impelling him to search means of saving human and animalkind from disease as justified in its resort to animal experimentation. He does so with the less heart-searching and with clear conscience because largely owing to Lister he can do so without inflicting pain and suppuration.
